Until about ten years ago elementary biology as understood by the Colleges was chiefly a matter of parasitic worms, but still the teaching had the merit of being founded on the principle that even the studies of the first year should have some practical bearing on medicine. The old arrangement, however, made necessary two distinct courses, one for candidates at the "College" examinations and the other for those belonging to the University of London and as this involved a considerable waste of energy the present syllabus, which is a feeble imitation of that for the preliminary scientific examination of the University, was adopted. It cannot be said to have been a success. It aimed at supplying at once an introduction to the serious study of biology and an exposition of the biological problems which are met with in medical practice and in both respects it has signally failed. Having satisfied the examiners that he can identify a cross section of hydra or the ovary of lumbricus the student hastens to forget all about those creatures and nothing in his subsequent medical career is likely to remind him of their existence. He has, perhaps, a vague notion that something lies behind them but there is no time to teach him what that something is; he must get on to the next "type." No wonder then that he remains as ignorant as the average layman of the part which natural selection, changes in the environment, hereditary tendency, and other biological factors have played in producing those complex human mechanisms with which he will shortly begin to occupy himself. And yet it is of the first importance that he should be familiar with topics such as these. More and more clearly is it being recognised by the world at large that any satisfactory scheme of practical morality must have a biological basis which professional theologians make no pretence of supplying, and the medical man is expected to make good the deficiencies of creeds and homilies. For the student of medicine the science of life should embrace much more than a little animal morphology tempered with a trace of the botany of the cryptogams and should deal as fully as may be with those principles which explain, however imperfectly, man's place in the scheme of things.

In the University of London, which, as already indicated, has influenced the requirements of the Conjoint Board, the courses of study for medical and scientific students overlap and from motives of economy the preliminary scientific studies of the former are arranged on lines which are only appropriate to the latter. It may be safely assumed that the practising physician has neither inclination nor opportunity to become a specialist in botany and zoology and it serves no useful purpose to base his limited study of biology upon work which is only of value if duly followed up. His peculiar need is to understand why man is what he is, and his interest is in the results rather than the methods of biological research. Palæontology, ethnology, psychology, and sociology are of no less importance to him than botany and zoology and all these branches should be laid under contribution.

To insist that a medical man cannot obtain a useful knowledge of biological matters without dissecting "types" is akin to reviving the obsolete method of studying the classics which requires the reader to hunt up all the words in a dictionary instead of profiting by the labour which has provided translations. Man is the only "type" which the physician can find time for. Let him therefore learn something of the springs of human conduct, of the religious sentiment, of the organisation of society, and of the other phases of man's kaleidoscopic personality. Of more strictly technical subjects he may ponder on the origin of living substance, the phenomena of growth and decay, the nature of that *vis medicatrix* without the aid of which all his arts are as nothing, and the host of similar problems which his daily round presents. If questions like these are too abstruse for his student days let him take biology at a later stage and spend his first year in the acquisition of facts relating to human anatomy or the materia medica. At any rate, let him not cherish the delusion that to pass the present examination will constitute him a biologist. The play of *Hamlet* without the Prince of Denmark is not more absurd than a synopsis in biology which makes no reference to the principle of evolution.

I am, Sirs, yours faithfully,

A FORMER TEACHER.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Vaccination in the Madras Presidency.—A Curious Petition against a Septic Tank.—The Plague.—Statistics concerning Bombay and Calcutta.

AN order has recently been passed by the Government of Madras formulating an elaborate scheme for the improvement of the working of the vaccination department. Hitherto the staff of vaccinators has been numerically inadequate and vaccination has made but slight progress. It may be said also that the class of men employed is open to improvement The staff is now to be graded and the pay is to be raised. The use of preserved lymph enables the vaccinator to cover more area than used to be the case when he had to secure lymph from the arms of previously vaccinated persons. The supervising agency will also be increased. Vaccination is not compulsory except in the towns, but it will be declared so in certain districts. The King Institute of Preventive Medicine at Guindy will supply the requisite lymph. From the last report about 66 per cent. of the children in the municipalities were vaccinated, with a reported ratio of success of 89·4, but throughout the whole presidency, with a total population of over 37,000,000, it appears that only 356,000 children under one year of age were operated upon, the births being recorded at 935,749. The death-rate of infants under one year is certainly not less than 200 per 1000 and with the imperfect registration of births is probably much more. The census of 1901 showed an infantile population (under one year) of 1,119,450.

A curious memorial has been presented to the Lieutenant-Governor of Bengal by some of the Hindu inhabitants of Rishnu, near Calcutta, complaining against the establishment of a septic tank intended for the use of mill hands. The sacred Ganges (Hooghly river branch) is to be polluted, the neighbouring shops are to be contaminated, and the religious feelings of the temple worshippers are to be outraged. The memorialists seem [illegible] latrine with any p[illegible] to ignore the common [illegible] as a latrine and of utilising any convenient spot by the roadside for the same purpose. That a public latrine used by thousands of mill hands close to the public road may be a nuisance if not properly constructed and managed is tolerably certain but that objection should be taken to the septic tank is merely an example of that passive resistance so characteristic of the Indian people. From time to time I have drawn attention to the installation of the septic tank system for the disposal of sewage at several mills anc [illegible] have only proved their use [illegible] of view of sanitation [illegible] investigation by experts will report before the prayers of an ignorant crowd are listened to.

The plague in Kashmir is fortunately subsiding. It is stated that the spread of the disease after the second case reported was due to the relatives and friends of the deceased who had attended the patient digging up his body at night because it had been buried without performing the usual religious ceremony. Some of the mourners soon after were infected and spread the disease.

Some interesting statistics concerning Bombay city were given by Dr. J. A. Turner at a recent public meeting. About 6000 persons are employed in cleaning the city. About 1000 tons of garbage have to be removed daily as well as about 500 tons of night-soil. The mean mortality from phthisis during the past 10 years is: Mahomedans, 11 per 1000 of the population; Hindus, 5 8 per 1000; Parsees, 1·4 per 1000; and Europeans, 0 3 per 1000. The total mortality from phthisis is 6 6 per 1000, as against 1·6 in London and 2·3 in Manchester. The mean annual infantile mortality is equal to 700 per 1000 of the births and the number of children under four years of age dying yearly is 12,000. In Calcutta also the death-rate from phthisis is very high, and the ratio of infants (under one year) dying is 491 per 1000 births. The Mahomedans lose 843·6 per 1000 births, while amongst the Hindus the rate is 401·3.

Jan. 22nd.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

THE BATTLE OF THE CLUBS AT SOUTHAMPTON.

FOR some time past the work of organising the profession at Southampton has made steady progress. It was the decision given by the General Medical Council in regard to the difficulty that arose at Great Yarmouth which brought matters to a climax at Southampton. Several practitioners in the latter town felt that they also were acting as medical officers of insurance companies employing canvassers and might be exposed to similar reprobation. One or two among them approached the secretary of the local branch of the British Medical Association and urged that some explanation should be forthcoming so as to enable them to know in what position they stood. The National Medical Aid Company, Limited, and the London and Manchester Insurance Company had branches in Southampton which employed medical men and there were some laymen who had clubs of their own. For instance, the agent of an insurance company which had no medical aid organisation found that this was a disadvantage. He therefore called on four or five medical men and organised a club of his own. His customers who insured their lives or their furniture were thus also able to insure against sickness. This agent took a penny per week from them all, whether men, women, or children, which he handed over to the medical practitioner after deducting from 15 to 20 per cent. for the trouble of collecting. Though the profession thus found itself in a somewhat parlous state the local branch of the British Medical Association did not take any action. It was in the habit of meeting only once in the year but its secretary personally took great interest in the attempts about to be made.

There is an old-established social and scientific society called the Southampton Medical Society and this body meets every month during the winter season. Though the subject was somewhat outside the usual scope of its discussions the question of club practice was put down on the agenda for one of the meetings. The medical men who then attended and discussed this matter felt that the only manner to deal effectively with it was to call a general meeting of all the practitioners of the neighbourhood. This was done. The first invitation was issued on Jan. 28th, 1902, for a meeting held on Feb. 6th. Other meetings followed in rapid succession and by Feb. 20th a scheme of organisation had been drawn up. This meeting of Feb. 20th was an important gathering. There were 28 practitioners present and this must be considered very good, as it was estimated that there were not more than 60 practitioners in the town and the neighbourhood. It was then decided to form a medical union "provided a practical unanimity was secured." On March 7th another meeting was held and an appeal was drawn up to the other practitioners urging them to fall into line. The first secretary, Mr. W. Hall, then resigned and was succeeded by Dr. W. Prior Purvis. By March 22nd sufficient progress in the work of organisation had been made to decide that to cover working expenses each member should pay 5*s*. a year. The greater part of the discussion held at the meetings related to the rules and the declaration of principles which every member would be called upon to sign. A large number of meetings were held so as to keep all the members well informed as to what was being done. Thus, in addition to many minor meetings there was a general meeting on April 15th and another on June 19th following As a rule these meetings were held after working hours—that is, at about 9 P.M. At the last-mentioned meeting a permanent executive committee of 11 was appointed in the stead of the temporary committee and on July 30th the following officers were elected:—Mr. J. F. Bullar as permanent chairman, Dr. H. W. Shettle as honorary treasurer, and Dr. A. A. Mackeith as honorary secretary.

The organisation was now therefore definitely constituted and it entitled itself "The Southampton Provident Medical Association." It had also by this time agreed upon its object and policy. There were a large number of church and chapel clubs at Southampton together with public house slate or sharing-out clubs. The members of these clubs who paid 1*d*. per week extra could have medical attendance. The question arose whether this could not be checked by raising the subscription from 1*d*. to 1½*d*. It was agreed that all the medical men should write identically the same letter to these clubs and also to the National Medical Aid Company, Limited, and to annual benefit clubs. Notices to this effect were to be given on Sept 28th, so as come into effect at the beginning of 1903. But it was decided that no action should be taken in regard to the registered friendly societies such as the Oddfellows, the Foresters, and the like, and some trade unions, notably the boiler makers. Though abuse undoubtedly exists in regard to these organisations, nevertheless there are not the same scandalous circumstances connected therewith as exist in regard, for instance, to some of the public-house clubs or the clubs connected with the churches and the chapels.

A general meeting was convoked for Sept. 2nd for the purpose of signing the bond and agreeing as to the text of the letter to be written to the clubs. 20 medical men attended. The bond was dated August 5th and after this meeting 49 medical men had signed it out of the 57 then in practice at Southampton. The following is the text of the bond in question:—

> Rules of the association, Article 23: " [illegible] the association shall sign a properly d[illegible] 1. That he will not take any contract pa[illegible] paid to the association except member[illegible] are recognised by the committee of t[illegible] friendly societies shall be kept by the [illegible] this list shall be submitted for approval to the next general meeting 2. That he will not advertise for patients directly or indirectly or treat patients sent to him by persons or companies who advertise for patients. 3. That he will not for a period of two years after the formation of the association accept any club which at that time was attended by another medical officer, except with the written consent of the original medical officer or of the committee of the association. 4. That he will not employ a collector or collect subscriptions from contract patients at their homes. 5 That he will obey the rules of the association and do nothing contrary to its welfare"

Members who, after signing the above, did not conform to these rules could be excluded from the association if at a general meeting convoked to discuss their case there was a two-thirds vote against them. Then Rule 25 stated that—

> No medical officer of the association shall meet professionally any medical man resident within the borough of Southampton, or carrying on contract medical practice therein, who is not a medical officer of the association or who has not signed a statement acceptable to the committee thereof, except in cases of immediate urgency and all such shall be reported to the committee within a week.

While determined to abolish or to reform the worst features of club practice the medical men of Southampton decided that they must also adopt a constructive policy. Therefore, instead of calling their organisation a medical union they have taken the title of Provident Medical Association and determined that they would themselves provide medical attendance and medicines for those persons not able to pay the ordinary medical fees. Every practitioner was to be induced to join the union either as an active member if he intended to treat poor patients on the contract system or as an honorary member if he did not, but in either case the entire profession must be brought into the movement. All were interested in the question, even those who had no club patients. Having thus decided that they would themselves provide what medical aid was necessary, the question of the collection of the subscriptions was one of the first difficult problems that had to be taken in hand. It was a very puzzling practical matter and the want of experience was keenly felt. If a collector was paid by results abuse was very likely to arise, for he would be tempted to enrol persons who could afford to pay medical fees. On the other hand, if he was not paid by results then he was tempted to be neglectful. It was decided that the latter was the less of the two evils and therefore the association resolved to pay its collectors a fixed salary and not to give them any commission for obtaining new subscribers. Indeed, they were instructed not to enter a new subscriber on their books unless the candidate had been examined by the medical attendant whom he had selected. Nor were the collectors to be allowed to collect for any insurance company. They might sell mangles and collect weekly payments for the same but must not deal in anything with which the question of insurance against sickness could in any way be associated. The collectors must find sureties; one of them has paid £25 into the bank. Three collectors have been appointed, one being paid £2 a week and the other two £1 each. They are men accustomed to the business and had already large collecting books—indeed, one of them had been working among the people whose clubs were abolished by the action of the medical men and who consequently came over to the association founded by the medical union. The rule was made that the collectors must pay the money they received into the bank every week so that if the payment was not made or if the sum differed in any marked degree from what was usually received inquiries could be instituted.

The next point was to divide the town into districts, so that each practitioner might choose the district where he could most conveniently attend to patients. The medical officers would continue to provide the drugs as in the past, but they would receive 1½*d* instead of 1*d*. per week. When the circular announcing this determination was launched on Sept. 28th, 1902, only five practitioners had not signed the agreement and joined the medical association. Two out of these five have subsequently joined, but one of them, though a young man, has practically retired. A third refused to sign because he had no club work whatsoever. Of the two remaining one is very old and did not feel capable of taking any action one way or the other and the fifth, though he refused to join the association, wrote saying that he would not undersell his fellow practitioners and promised not to take any new club except at the increased rate of payment.

The first start was therefore made under the best auspices, but weak points became manifest when once the organisation got under way. Early in the history of the movement one of the members resigned. He pleaded that he had a wife and family to maintain, that his patients could not pay more than 1*d*. per week, and that he could not afford to lose them. He did not seem to understand that he would get more by the proposed change. He was afraid of the risk and therefore resigned. Two other unfortunate circumstances occurred that were not directly connected with the medical organisation but affected it considerably. There was a benefit club called the Dock Friendly Society. This was a registered friendly society and the movement was not intended to affect such bodies. But the medical officer attached to this club was not satisfied. He found that no new members joined, that the average age of the members was 44 years, and consequently there was a great amount of sickness in proportion to the very small pay. At a penny a week it is only possible to attend to the members of a society on condition that there should be a normal proportion of young and healthy members as well as the old and the infirm. [illegible] gave rise to th[illegible]d be attacked. [illegible] firm of practitioners who refused to attend a lodge of female Oddfellows. These [illegible] to do with the organisation [illegible]t established but the friendly [illegible]nd imagined that they were seriously menaced. They said that the medical men had begun with the weak societies but would soon be attacking the stronger ones. The medical officers attached to the male lodges of the friendly societies held a meeting and declared that they had no intention of raising their charges. Nevertheless, and so as to be independent of the medical men's organisation, the female lodge of Oddfellows and the Dock Society advertised for a medical officer and so did the National Medical Aid Company, Limited. This company had started business in Southampton some 15 years previously. It employed five medical practitioners. Whenever there was any difficulty with one of them the company at once imported a new practitioner into the town. They probably paid in all about £250 a year to be shared by their five medical officers at the time the Southampton Provident Medical Association was started. When these five medical officers resigned the subscribers were told to join the association formed by the united profession. In any case this was the only means by which they could retain their usual medical attendants. The collectors of the National Medical Aid Company, on the other hand, went their usual rounds announcing that new medical officers had been appointed and did not say anything about the formation of the association by the former medical officers. The company had imported three medical men and strove to make them do the work of the five who had resigned. This, however, did not succeed. The patients preferred their old attendants even though this meant an increase of 50 per cent.—that is to say, 1½*d* instead of 1*d*. per week. The three imported medical men received so little support that the National Medical Aid Company gave up the struggle altogether and has now ceased to exist in Southampton. Thus at least in this point of the field the victory was complete.

The Dock Friendly Society had also imported a medical practitioner; and as it had not enough work for him it took the initiative in founding what is called the *Southampton Benefit Societies Medical Federation*. Some of the annual benefit societies joined and the federation claims to have over 2000 subscribers. This membership at the old rate of 1*d*. a week did not provide much of an income for the medical men who had been imported into the town. But the insurance companies encouraged them to form private clubs with the members for whom these companies used to provide medical aid. The London and Manchester, however, which had been collecting 1½*d*. a week and paying its medical officers only from 3*s*. to 4*s* a year, handed over all its subscribers and the 1½*d* to the Southampton Provident Medical Association but they had only 144 members. Still it was a help.

The greatest cause of success, however, was the attachment of the people to their medical attendants. When they found that these medical officers meant to manage their own business themselves they could not but acknowledge that this was fair. It is no advantage to the patient that some individual or some club should step in between him and his medical attendant and "sweat" a profit out of the latter. It was also felt that the charge of 1*d*. a week was instituted more than half a century ago and that wages have increased considerably in the interval, so that it is now time to augment such payments. Nevertheless, it was no small undertaking. By giving up the old contract work at 1*d*. per week it was calculated that some 10,500 persons would be affected. More than a year has elapsed since the struggle began and it is now estimated that the Southampton practitioners have lost about 3500 subscribers who are paying a penny a week to the imported practitioners. On the other hand, the members of the Southampton Provident Medical Association have about 7000 subscribers [illegible] This includes 4000 [illegible]nisations and mean[illegible]nbers of the medical [illegible] two-thirds the amount of work which they did formerly and they receive if anything rather more pay. The cost of collection, the clerk, the printing, in fact all the working expenses, amount to about 21 per cent. of the receipts. Therefore the medical officers receive in cash and net 4*s*. 10½*d*. per member, whereas formerly they never had more than 4*s*. 4*d*., and from this latter sum the cost of collecting was very often deducted. At the same time there is much less abuse and canvassing, undercutting, and unfair competition have been altogether abolished. The tone of the profession has been thus raised, yet no financial loss has been experienced. All the members have remained faithful to the Association and the newcomers to the town, six in all, have joined the union of the Southampton practitioners. The general feeling therefore is one of great satisfaction. The worst elements of contract work have been abolished. The great majority of subscribers are paying 6*s*. 6*d*. per annum and thus provide an object lesson that shows this is not more than they can afford. These excellent results would not [illegible] so easily but for the fact that the work [illegible] much easier by the energy and [illegible] Mr. J. F. Bullar, who has acted throughout in a most disinterested manner, having no club practice or personal interest to serve. The secretary, Dr. A. A. Mackeith, is likewise unremitting in his attention to the wearisome details of organisation and has always displayed great tact and activity. The policy pursued has been absolutely opportunist, attacking only where there was a real chance of success, and the results so far are very good. Perhaps this will [illegible] ocieties to reform themselv[illegible] Short of this *measure* it [illegible] Medical men cannot be [illegible] to attend well-to-do tradesmen for a penny per week because they happen to be members of such societies as the Oddfellows or the Foresters. This matter has not yet been raised in Southampton. Very cordial relations prevail between the friendly societies and their medical officers but the grievance is there, the abuse does exist, and it is for the friendly societies to maintain the peace by abolishing the abuse. But I must add that these last remarks convey only my personal opinion. In no way am I reflecting what was said to me by any responsible member of the Southampton Provident Medical Association. These observations about the abuse prevailing among the old-established friendly societies are neither official nor officious. They can therefore be taken in good part. They cannot be interpreted as a threat. They represent but an outside opinion and for that reason are perhaps worth considering, if only because they are impartial and disinterested.

THE "MEDICO CONDOTTO" OF ITALY.

(FROM OUR ROME CORRESPONDENT.)

THE term "medico condotto" is applied in Italy to the medical man employed to attend upon the sick poor of a commune and is derived from the "condotta" or area over which his work is "conducted." The appointment is in the hands of the communal council which selects for the service one or more of the medical practitioners already resident in the commune, or if none such is available the law obliges the commune to appoint at least one medical man to the post with or without a competitive examination. When a commune is unable by itself thus to provide gratuitous medical attendance for its poor it may combine with one or more of the neighbouring communes for that purpose. The respective communes entering into such a union or *consorzio*, as it is called, elect representatives in proportion to their population and taxation to form a *consiglio consorziale* the duty of which is to administer the sanitary affairs of the union.

An uninterrupted occupancy for a period of three years of the office of *medico condotto* is necessary under the present law to enable the holder to acquire fixity of tenure, and after the lapse of that time the communal council has no power to dismiss him except for reasons approved by the prefect acting on the advice of the provincial council. Against such dismissal the *medico condotto* has a right of appeal to the Minister of the Interior. The first three years of service are thus regarded as a period of probation during which the communal council may exercise its right of dismissal without necessarily assigning any reason. Before the expiry of the three years the council must hold a special meeting and decide by vote whether the services of the *medico condotto* are to be retained or not. Should the decision be favourable his position becomes *ope legis* established. The salary given by a commune to the *medico condotto* varies from about 1500 lire (£60) to about 2500 lire (£100) per annum. Although the remuneration is so poor there is no lack of candidates for vacancies. Country practitioners in Italy being numerous and badly paid these posts are eagerly sought after, the more so for the reasons that those holding them are free to engage in private practice and that after a certain period of service they become entitled on retirement to an indemnity or to a pension. The pension is granted to those who have been in effective service for 25 or more years and likewise to those who through wounds or illness contracted in the discharge of their official duties have been incapacitated for further service at any time after their three years of probation. The indemnity is accorded to those who after ten or before 24 years' effective service are unable to discharge their duties on account of illness contracted from causes other than those above mentioned or who have passed into other departments of the Government service. The pension or indemnity is supplied by a fund formed by various contributories, including the communes, benevolent institutions, and the *medici condotti* themselves, as well as by donations and bequests. To secure the minimum amount of pension the *medico condotto* must contribute 60 lire (£2 8*s.*) per annum during the whole period of his service together with a further contribution during each of the first ten years of 72 lire (£2 17*s*). This amount is obligatory upon every *medico condotto*, but he may contribute 100, 140, or 180 lire per annum and thus secure a higher pension. Thus, after, say, 25 years of service one who has paid the minimum premium to the pension fund is entitled to an amount varying, according to his age, from 506 lire (at 47 years) to 2500 lire (at 77 years) per annum. By contributing the higher annual payments he becomes entitled to a pension one-third or two-thirds greater or twice as great respectively, but in no case may the amount of it exceed 5000 lire (£200) per annum.

A Bill, already approved by the Chamber of Deputies, is now awaiting the assent of the Senate, which modifies in several particulars the law as it stands at present. Of the proposed modifications the most important are the following: (1) The appointment of the *medico condotto* must be made by a commission nominated by the provincial sanitary council after competitive examination and not as at present by the communal council; (2) the time necessary to acquire fixity of tenure is reduced from three to two years; and (3) the dismissal of the *medico condotto* must be agreed upon three months before the lapse of the probationary period. These changes are strongly opposed by the medical profession in Italy who want the power of appointment to be retained by the communal council and contend that fixity of tenure should be assured from the day of appointment and that the period of probation should be entirely abolished. In the case of unions it is pointed out that on the plea of reorganising the sanitary service the *consiglio consorziale* has the power to rid itself of its medical officer at a moment's notice without any pretext whatever by simply dissolving the union. In such circumstances the *medico condotto* would lose his position even after having served the time necessary for gaining his fixity of tenure, and this without receiving any compensation. As to the question of dismissal, it is urged that this should be determined only upon grounds of a serious nature which the *medico condotto* should be given the opportunity of disputing and that a right to appeal to the provincial council should be allowed to him. A demand is further made that annual leave of absence for a reasonable time should be granted to him. It is understood that the new Ministry which has come into office since the Bill passed the Lower Chamber regards the proposed modifications with favour and it is hoped that these and other suggestions for improving the measure which have been recommended by the council of the *Ordini dei Medici* will be adopted by the legislature. The result of the change would be a considerable amelioration in the position of the over-worked and under-paid *medico condotto* whose lot at present is not a happy one.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University Matters.

THE annual meeting of the court of governors was held on Jan. 28th, the Chancellor, the Right Hon. Joseph Chamberlain, presiding. The pro-Vice-Chancellor, in moving the adoption of the report and balance-sheet, alluded to the fact that further annual income would shortly be required, as large sums would have now to be paid out of capital for the construction of the new buildings in process of erection. Sir Oliver Lodge, the Principal of the University, in seconding the motion, stated that a small deputation was shortly to meet the Chancellor of the Exchequer with a view of endeavouring to induce him to increase the grants at present given to University Colleges. He also alluded to the urgent need of residential hostels in connexion with the University. The Chancellor laid stress upon the fact that Government assistance ought not to dispense private individuals and local authorities from their duty of providing funds for university purposes. He drew attention to the fact that whilst Staffordshire and Worcestershire gave annual subventions to the University Warwickshire, in which the greater part of the city is situated, had as yet subscribed nothing. He also alluded to the larger boroughs and municipalities in the neighbourhood and hoped that they too would recognise the propriety of making annual grants towards the funds of the institution. Contrary to general expectation no person raised the question of the vivisection licences which the University has recently obtained. It is to be supposed that the anti-vivisectionist party is convinced of the uselessness of maintaining the local conflict any longer. On Feb. 4th Sir Oliver Lodge delivered the first of his four lectures on physics and therapeutics to an audience of medical men representative of the whole of the Midlands and numbering more than 300 The lecture, which was illustrated by lantern slides and by numerous experiments, dealt, after some introductory remarks, chiefly with the subject of the cathode rays and with radium and other substances of the kind. A new substance named polonium was exhibited the emanations from which can be deflected by the breath, so as to discharge the electroscope. On Feb 5th a special address was delivered to the Anatomical and Anthropological Society by Professor A. M. Paterson of the University of Liverpool who took for his subject the Morphology of the Sternum. The audience, over which the President of the society (Professor B. C. A. Windle) presided, was much interested in the address and in the numerous specimens with which it was illustrated, and a vote of thanks was passed to the lecturer on its termination.

Guest Hospital, Dudley.

A meeting of ministers of religion has recently been held at the Guest Hospital and in combination with the board of management of that institution with the object of inquiring how it is that the sums subscribed on Hospital Sunday have so much fallen off and that in a number of churches and chapels no collections are made for this purpose. The Rev. Mr. Warren, a Congregationalist minister who recently came to Dudley, seems to have stirred up discontent with the arrangements made in past years for the religious visitation of the patients, though these arrangements appear to have worked smoothly enough for a number of years. At the meeting in question this gentleman stated that the arrangements alluded to were the cause of the falling off in the subscriptions and that he and others would not help the hospital until Nonconformist ministers were admitted to the hospital on terms of perfect equality with others. As a matter of fact there is at present an Anglican chaplain, though his services are, so far as the hospital is concerned, honorary. There has been such a chaplain for over 30 years and his visiting days have been Tuesdays and Fridays. Some years ago the Free Church Council asked to be allowed to appoint a minister to visit the hospital. This request was complied with and Mondays and Thursdays were allotted to him as visiting days. Wednesdays and Saturdays being the general visiting days it was obvious that there was not much choice left in this matter. Of course, it goes without saying that any patient is allowed at any time to see the clergyman of his choice should he specially request to do so and circumstances permit. Mr. Warren, however, complained that the days allotted for visiting to the Nonconformist minister were those devoted to the cleaning of the wards, which were often in a state of confusion. He also stated that he had been denied admission by the acting chaplain, a statement which has been contradicted. Finally, he contended that Nonconformist ministers should have the right of holding a service once a week as the chaplain at present does. Since the meeting alluded to the matter has been further discussed by the weekly board, a proposition having been ma[illegible] should be appointed in [illegible] proposition, after being f[illegible] large majority.

Bathing Statistics in Birmingham.

1903 was not a year in which bathing was greatly encouraged by climatic conditions, but in spite of that fact a very large number of persons availed themselves of the corporation baths during the last nine months According to a return prepared by the superintendent 330 790 bathers attended the baths exclusive of the Green-lane Bath and the two open-air swimming-baths, being an increase on the corresponding period of the previous year of 22 410. The receipts have correspondingly increased by £84. The return for the whole of the corporation baths shows an increase of 109 585 and of £803 in the receipts. The Green-lane baths, which have largely added to the figures, were, however, not opened until November, 1902. During the past year 67,048 boys from the elementary schools were admitted to the corporation baths as compared with 33 017 during 1902 and 826 boys succeeded in passing the swimming test as against 590 in the previous year.

Feb 7th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

University of Manchester.

A MEETING of the court of governors of the University of Manchester was held on Feb 4th in the council chamber of the Owens College. The Vice Chancellor (Dr. Alfred Hopkinson) presided. He said that the special object of the meeting was to obtain the assent of the College Court and the University Court [illegible] the cc[illegible] Univer[illegible] body [illegible] constitution had been modified. The officials of the University would remain in office. Lord Spencer is willing to remain Chancellor of the University. The Duke of Devonshire, the President of the Owens College, would become President of the Victoria University of Manchester and, in the absence of the Chancellor, would preside at meetings and confer degrees. He hoped that the Duke of Devonshire would accept the office. The arms of the College, it was suggested, should be the arms of the University, "and in all respects there would be a complete merging of the College in the Victoria University." A motion approving of the Bill was passed. The Vice-Chancellor then left the chair which was taken by Mr. Alderman Thompson, chairman of the governors of the Owens College. A motion similar to that just adopted by the University Court was passed by the governors of the College. Mr. Alderman Thompson then left the chair which was again occupied by the Vice-Chancellor and the proceedings of the University Court were resumed. When these somewhat Gilbert-and-Sullivan-like performances had been satisfactorily accomplished the Faculty of Medicine came on to the stage and Professor Stirling proposed a motion upon the constitution of the Faculty of Medicine whereby it was agreed that in addition to the professors of the subjects taught in the medical school and the assistant lecturers —Mr. J. Grier, Dr I. Walker Hall, Mr. J. E. Platt, Mr. E. J. Sidebotham, and Dr. R. T. Williamson—the Faculty shall consist of the following: (1) Professor H B. Dixon, Professor S. J. Hickson, Professor W. H Perkin, Professor A. Schuster, and Professor F. E. Weiss; (2) Dr. H. Ashby, Mr. G. W. Mould, Mr. J. Collier, Mr. W. Thorburn, Dr. C. E. Glascott, Dr. Lloyd Roberts, Dr. J. Niven, Dr. H. A. G. Brooke, Dr. A. Hodgkinson, Dr. W. Milligan, Dr. E. S Reynolds, Dr A. K Gordon, Dr. T. Harris, Dr. Graham Steell, Dr. J. S. Bury, Mr W. P. Montgomery, Dr J. Scott, and two members to be nominated by the dental committee; and (3) Dr. F. C Moore, Dr. A. W. W. Lea, and Dr. W. E. Fothergill. Dr. Clegg seconded the motion and it was passed. On the motion of Professor Hickson, seconded by Mr. Alfred Haworth, it was resolved that the period of office [illegible] the Vice Chancellor then [illegible] public meetings of the [illegible] a formal sentence in [illegible] business was over. The words suggested by the new professor of Latin were: 'Salva sit Universitas nostra Mancuniensis: hoc precantes consurgamus.'"

The Royal Infirmary.

The report of the Manchester Royal Infirmary just issued shows that the change from the old to the new has really begun. It may be remembered that the corporation agreed to pay £400 000 for the present site in Piccadilly. The first instalment of £100,000 has now been received. The formal conveyance of the Stanley-grove site from the Owens College to the infirmary is almost completed. The board has enlarged the new site by the purchase of three houses in Nelson-street which gives a frontage in a good street at right angles to Oxford-road It has also arranged for the relinquishment by the Manchester Southern Hospital of a further piece of ground on the payment by the board of £18,500 and it has agreed to pay £6000 to the Owens College in compensation for the expense involved in the removal of its bacteriological laboratory from Stanley grove and towards the acquisition of a suitable adjacent site. 56 architects wished to compete for the building of the new infirmary and of these 12 were selected by Mr. J. J. Burnet, the assessor recommended by the president of the Royal Institute of British Architects. Their designs are now receiving careful consideration. As soon as the plans are decided on the board will consider if any, and if so what, provision for accident and urgent cases and out-patients shall be made in the centre of the city. In the new infirmary there are to be 500 beds with provision for 600 and in connexion with it there is to be a permanent memorial of the late Queen. For this purpose the sum of £13,178 9*s* 7*d* has been received from the committee of the Queen Victoria Commemoration Fund. During the past year there has been great pressure on the accommodation, 5199 patients being treated in the infirmary, 38,964 as out-patients, 1548 as home patients, and 1707 at the Barnes Convalescent Home. The income of the infirmary for the past year was £24,755 and that of the Barnes Hospital was £2797, while the expenditure of the former was £19,782 and of the latter £6617.

Small-pox at Stretford.

Stretford, the close neighbour of Manchester, has had an outbreak of small-pox which threatened at one time to assume serious proportions. At the last meeting of the district council Dr. W. J. Heslop, the medical officer of health, was able to say that it had ceased and that no case had been notified since Jan. 2nd. It is pleasant to know that the exertions made to limit the outbreak have been appreciated, for as one of the members said at the meeting, "the sanitary committee, Dr. Heslop, and those who worked so well with them were deserving of the thanks of the district for their exertions which had proved so successful."

Mussel Poisoning.

A case of death after eating boiled mussels came before the Bolton coroner last week. A man sat down with his family to tea, at which they had boiled mussels. He almost immediately had symptoms of poisoning and died in 15 minutes. No details are given but the medical man is reported to have said that it was not a case of ptomaine poisoning, that the mussel was not bad, that mussels might appear perfectly fresh and yet be poisonous, and that the poison was naturally developed in the body of the mussel itself. This is, of course, something distinct from their unwholesomeness when impregnated with copper. The explanation of one mussel among the millions eaten producing such startling and deadly effects has not yet been given.

Hulme Day Nursery.

One of the factors in the production of the heavy infantile death-rate of our towns is the necessity which compels so many women to leave their young babies in the charge of old women past work, while they themselves go out to earn their daily bread. Sometimes these caretakers are worthy of the trust but they are often careless and generally ignorant. Eleven years ago the Hulme Day Nursery was founded, largely through the efforts of the late Dr. Haden Guest, to lessen the evil as much as possible, and the annual meeting was held on Feb. 1st, the Lady Mayoress presiding. For 3*d.* per day a child is taken into the nursery, fed, washed, and cared for between the hours of six in the morning and six in the evening. Only those are admitted whose mothers have to go out to work and the children of widows have the precedence. Last year there were 2358 attendances, rather fewer than in the previous year, but this was due to lack of work and not to loss of popularity of the nursery The total receipts were £189 and a credit balance of £16 was left. In seconding a vote of thanks to the officers the Rev. J. Lightfoot, rector of St. Michael's, Hulme, said, with too much truth, that the district was fast becoming the most squalid, most thickly populated, and most neglected part of Manchester. In this large district, containing about 100,000 people, there is not "a single open space where the children can play. We are badly lighted, badly drained." There are very few large employers who can do much for the people and Hulme does not seem to have become fashionable among the philanthropic workers who have flocked into Ancoats and Angel Meadow, which are not "more in need of help, more poverty-stricken in every sense of the word, than certain parts of Hulme." It may surely be hoped that his appeal will be followed by good results. It is a district which would be greatly benefited by the establishment of more cottage baths and wash-houses and more day nurseries.

Feb. 9th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Insanitary Elementary Schools.

THE managers of voluntary schools appear to have been dealt with very tenderly by the Board of Education, which does not seem to have been very insistent upon the managers making structural alterations which would have improved the sanitary condition of certain schools. The result is that in many places when county councils have required an inspection of these non-provided schools as they are now called a very unsatisfactory state of affairs has been revealed. In Pembrokeshire among 68 schools reported upon it was found that four actually required to be rebuilt before they could be considered fit for use, eight required to have more than £200 spent upon them, 24 more than £100, and upon the remainder it was necessary to spend sums varying from £5 to £50. The chairman of the county education committee stated that a few schools were in a condition too revolting to have details disclosed—they were simply shocking. In some parts of North Wales the same unsatisfactory conditions are to be found and on Feb. 3rd the Flintshire county council passed a resolution calling the attention of the Board of Education to the state of many of the elementary school buildings in the county, especially with regard to the structure and sanitary arrangements. One member of the council attributed the frequent epidemics in the county to the insanitary condition of some of the schools. He stated that during five years six schools had been closed for 64 weeks owing to outbreaks of scarlet fever, measles, or diphtheria.

Victoria Hospital, Frome.

The handsome buildings of the Victoria Hospital at Frome were erected in 1901 to commemorate the Diamond Jubilee of Queen Victoria. The usefulness of the institution is now well established and the managing committee has reason to be thankful for the support given to it by the townspeople and others. There are 16 beds in the hospital and more than 100 patients were treated in the wards during 1903. The expenditure for the year was £766 and the income was £879.

West Wales Sanatorium.

When the scheme for the erection of a sanatorium for consumptive patients was first brought forward it was confidently expected that the county councils of Carmarthenshire, Cardiganshire, and Pembrokeshire would each contribute towards the erection of the building, following the example of other counties, notably that of Westmorland. This anticipation has not been realised in the case of the Pembrokeshire council, for on Feb. 2nd it was decided upon the recommendation of the finance committee, not to make any grant in aid of the proposed institution.

Death in a Bath.

The necessity for having a bell in a bathroom has been once more illustrated at Swansea, where a woman, 50 years of age, was recently found dead in a bath. At the inquest which was subsequently held Mr. J. Lloyd Jones expressed the opinion that the deceased woman had vomited into the bath, had become faint, and falling on her face was asphyxiated. If this was actually the case (and there is no reason to think otherwise) she would probably have been able to ring a bell for assistance had one been provided. An admirable form of bathroom bell has been installed at the Newport and Monmouthshire Hospital where the bell rings in a nurse's or attendant's room and continues ringing until a cord is pulled outside the bathroom door so that the possibility of the signal being neglected is very remote

Newport and Monmouthshire Hospital.

The directors of the Newport and Monmouthshire Hospital, in which there is now accommodation for 100 patients, have of late years been able to keep their expenditure well within their income, but in their report for 1903 they have to record a loss upon the year's working of nearly £300 due apparently to a falling off in the income derived from general subscribers. It is satisfactory to find, on the other hand, that the working classes display an increasing interest in the hospital, for the subscriptions to the workmen's fund, which in 1901 amounted to £1200, have increased to £1450 last year. The men employed by one firm contributed as much as £209. The rules of the institution have been so altered that the subscribers to the fund are entitled to one representative upon the board of directors for each £200 contributed. The hospital is so well arranged and the new buildings are so well equipped with modern appliances that there should be no difficulty in obtaining additional support from the inhabitants of the town which is rapidly *increasing both in size and in prosperity.*

Discovery of Neolithic Human Remains.

Mr. St. George Gray, the curator of the Taunton Museum, has just examined, at the request of the Somerset Archæological Society, a human skeleton which has been discovered in Gough's Caves at Cheddar. Mr. Gray believes the remains to be those of a cave-dweller who lived between the Palæolithic and the Neolithic ages. The skeleton, which was found between two layers of stalagmite, belonged to a man who was 5 feet 3 inches in height. Flint implements of the type used by cave men were near the skeleton.

Infectious Diseases and Dockyard Employés.

Rear-Admiral W. H. Henderson, superintendent of Devonport Dockyard, on Feb. 2nd issued an order that when workmen have infectious diseases in their families they are not to go to the dockyard to draw their pay but are to arrange with fellow workmen to get it for them. Previously when there has been infectious disease in the house of an employé he has not been allowed to work in the dockyard but he has not been stopped from drawing his wages personally.

Feb. 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Shell-fish on the Coast of Ireland.

AN interesting and important report has recently been presented by the Local Government Board to the Lord Lieutenant of Ireland dealing with the conditions under which edible shell-fish are cultivated. The result of inquiry shows that "shell-fish are at present laid in places on the Irish coast which are grossly polluted and that there is a comparatively large number of layings the purity of which is open to doubt." Referring to Dublin Bay it is said that the total output of oysters from it and the Malahide inlet is about 25,000,000 while as many as 100,000 are sent from the beds each week. Dr. T. J. Browne states his opinion "that all the shell-fish in Dublin Bay are more or less subject to contamination," while Mr. D. Edgar Flinn considers that it is a question of importance whether shell-fish may not have played a part as one of the causes of enteric fever in Dublin At various times during the past few months personally collected samples of cockles and mussels from Dublin Bay have been pronounced to be sewage polluted by Professor E. J. McWeeney and he expresses the opinion that the gathering of shell-fish (cockles) within the estuary situated at Clontarf should be discontinued until the sewerage of this populous district has been dealt with. The Local Government Board recommends that the whole question of the cultivation and sale of shell-fish should be made a matter of special legislation

The Ulster Medical Society.

At the fourth general meeting (session 1903–04) held in the Medical Institute, Belfast, on Feb. 4th a motion was unanimously passed, proposed by Dr. Thomas Houston and seconded by Dr. H. O'Neill, supporting the resolutions sent to His Majesty's Government by the council of Queen's College, Belfast, with reference to the better equipment of that college. Dr. J. C. Martin (Portrush) showed a pathological specimen of Atheromatous and Aneurysmal Condition of the Abdominal Aorta and Iliac Arteries taken from an elderly male patient and gave details of the case. Mr. A. B. Mitchell opened a discussion on the Surgical Treatment of Malignant Tumours of the Breast, illustrated by a number of cases and a lantern demonstration of numerous photographs and microscopic preparations. Details of 30 cases were given, with remarks on diagnosis, prognosis, methods of operation, &c., and the question of subsequent recurrence. In the discussion which followed Professor T. Sinclair, Dr. Charles Kevin, Professor J. W. Byers, Dr. Martin, Mr. Robert Campbell, Dr. James Lynass, Sir William Whitla, and Professor J. A. Lindsay took part. Mr. Mitchell also showed a man on whom he had performed Subperiosteal Resection of the Clavicle with every movement of the shoulder girdle preserved.

Influenza in Belfast.

At present there is a widespread epidemic of influenza in Belfast, the main symptoms being sudden onset, high fever, general aching, and a laryngeal cough. The depression afterwards is not so marked as in previous attacks.

Fever-stricken Arranmore.

The island of Arranmore, which lies a few miles off the Donegal coast, with its inhabitants of about 2000 (mostly fishermen and small farmers), has achieved an unenviable notoriety for its severe epidemics of typhus fever during the past few years It was from fever contracted in this island, when conveying fever-stricken patients to the mainland, that Mr. William Smyth lost his life. Dr. B. MacCarthy, medical inspector of the Local Government Board, brought before the notice of the Glenties rural district council on Feb 6th the condition of many of the houses on the island which revealed a terrible state of affairs. The Congested Districts Board, which owns the island, has made most generous offers to the inhabitants to improve their miserable dwellings and, acting wisely, on the suggestion of the medical inspector, the Glenties rural district council has decided to serve notices on those who have insanitary houses to put them in order and to urge those people with insanitary houses to avail themselves of the offer of the Congested Districts Board.

The Belfast District Lunatic Asylum.

From the report of the inspector of lunatics (Sir G. O'Farrell), presented to the committee on Feb. 8th, it [illegible] but that the [illegible] no provision [illegible] and special cases. It is hoped that the committee will proceed with the erection of such buildings as will provide sufficient and suitable accommodation for all the patients under its charge. At present there are 507 male and 565 female inmates—total, 1072; on the asylum register at Belfast, 720; at Purdysburn, 290; and at Ballymena annexe, 62

Royal Victoria Hospital, Belfast.

The Right Hon. Thomas Sinclair, D.L., of Hopefield, Belfast, and his family have given £1000 to endow two beds in the "Sinclair" ward of the Royal Victoria Hospital, Belfast, to be called "Sarah Archer Sinclair" and "Elizabeth Ivan Sinclair."

Queen's College, Belfast, and the Royal Victoria Hospital, Belfast.

The Lord Mayor of Belfast (Sir Otto Jaffe) has intimated his intention of presenting a 60 milligramme tube of radium to the Queen's College, Belfast, with the stipulation that it should be available in the Royal Victoria Hospital for use there and should be brought to the College for demonstration as required. The cost is £63 and probably at the time of delivery it will be worth £100.

Feb. 9th

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Elastic Springs as Labour saving Agents.

SINCE the time that human muscular work has been studied by the same methods and in accordance with the same laws as in the case of mechanical motors more attention has been given to the question of output and to the maximum utilisation of work with the minimum expense. M. Marey showed 20 years ago at the Academy of Sciences that in the work of traction there was a considerable saving of labour when inelastic cords or connexions were replaced by springs Experimenting with a man fastened to a small cart and drawing the same load at the same speed for the same distance he compared the effect of traction by means of a rope with traction by means of an elastic apparatus and obtained accurate measurements with a dynamometer. He found that in the latter case there was a saving of 20 or 25 per cent. During the present week two captains in the artillery, MM. Machart and Ferrus, have made known the results of experiments which they have for 18 months been conducting on the drawing of artillery by horses They found that when the same horses drew the same carriages over the same distance and in the same time an additional load of one fourth or one-fifth could be carried when springs were employed. Following up this idea M. Breuillard has shown before the Therapeutical Society a small appliance which he has called a "calcanette." It is slipped into the boot or shoe under the heel and is merely a spring on which the heel rests when the foot is placed on the ground and which tends to lift the heel when the foot is raised. This little appliance in no way inconveniences the wearer who very soon becomes accustomed to it. It is a great assistance in the act of walking, reduces fatigue, and permits the same amount of work to be done with much less effort. It will render much service to Alpine climbers and especially to soldiers. It is about to be tried in the army.

New Rules for the Competition for the Position of Hospital Physician.

The system on which these competitions are conducted has long been considered by everybody to be unsatisfactory; it has several times been remodelled and has just undergone a new transformation. It is to be hoped that this will be final and it must be admitted that the new regulation is drawn up in such a way as to insure all possible impartiality in the work of the jury. Hitherto it has always been the case that a member of the jury might in complete security procure the nomination of one of his pupils by having a mutual understanding with other jurors who were doing the same thing but this will now be impossible. The competition will for the future be in two parts and there will be two examinations, each with a different jury, no member of the first jury taking part in the second. The first examination confers on those who pass it the right of "admissibility" for five years and only such candidates are eligible for the second examination. For the first examination two written papers and a report of a patient's case are required. Of the written papers one is on a subject of pathological anatomy, pathological physiology, or bacteriology; the other is on a question of symptomatology, diagnosis, or therapeutics. The jury is divided into two portions by the drawing of lots and each of these portions decides separately with respect to one of the written papers. The report on the patient's case is considered by the whole jury. The second examination is also decided by the new jury as a whole. It consists in making a clinical report on a patient's case. The candidate is allowed 15 minutes for examining the case and an equal time for giving his opinion on it to the jury orally after five minutes' consideration. The number of candidates declared admissible at the close of the first competition is to be such that the candidates for the nomination competition shall not exceed twenty.

The Treatment of Tuberculous Arthritis.

Professor Lannelongue devised, some years ago, an original method of treatment for tuberculous affections of the joints which he called *méthode sclérogène.* The object of the treatment was to transform the tuberculous tissues into fibrous tissue by the injection into them of a few drops of a 10 per cent. solution of chloride of zinc. Professor Lannelongue obtained numerous successful results by this method and it has now been improved upon by one of his pupils, M. Villemin, who, previously to the injection of the zinc chloride into the tissues around the joint, injects into the joint cavity, three days before using the chloride, some iodoform. By this means the tuberculous articulation is treated both inwardly and outwardly. M. Villemin has met with great success and at the meeting of the Academy of Medicine held on Feb. 2nd he read a paper on his cases. Professor Lannelongue, who was present, agreed with M. Villemin and in reply to those who objected that the method was one requiring extreme delicacy he replied as follows. It is true that to inject the chloride of zinc only into the tuberculous tissues and not into the joint cavity, where it would set up acute inflammation, requires a certain dexterity, but this is very easily acquired. The great point is not to hurry the procedure and not to expect the joint to recover its functions too soon. Three or four months must elapse before the tissues can be considered normal and five months must be allowed to pass before the patient is allowed to use his joint. If any stage of the treatment is hurried, or if forced movements are employed with a view to avoid the formation of adhesions, an acute inflammation may be set up which will undo all the good already acquired. M. Villemin has treated nine patients by this method with perfect success.

Feb. 9th.

Obituary.

GEORGE THIN, M.D. St. And., L.R.C.S. Edin.

Dr. George Thin, whose death took place at Nice at the end of last year after an illness of more than a year's duration, was educated at Edinburgh, taking the L.R.C.S. in 1858, and two years later the M.D. of the University of St. Andrews. After obtaining his qualifications he practised in Scotland, but in a very short time he proceeded abroad to Shanghai, where he was engaged in practice for some eight years. During this period he gained an extensive experience in all forms of tropical disease, an experience which with ripened judgment in after years brought him considerable fame in this branch of medicine.

In 1873 Dr. Thin returned to England and decided to settle in London where he practised for the remainder of his life. In the early part of his career at home he devoted considerable time to the study of dermatology, proceeding to Vienna and other places in order to acquire knowledge of this subject. The experience gained from practice in this field led him to contribute many papers to the medical journals and in addition he published a monograph on "Cancerous Affections of the Skin" and a book on "Ringworm." But Dr. Thin's chief interest lay in the direction of tropical disease and he worked with enthusiasm in this field of medicine at a time when no attention was paid to the subject by the public or the medical profession. His acquaintance with tropical disease gained in China and confirmed by much after-study both abroad and at home rendered his name well known to those who had been resident in hot climates. The disease to which he paid most attention was sprue and he published a valuable book on this subject entitled "Psilosis or Sprue" which won him wide recognition. To Dr. Thin it was largely due that the exclusive milk diet treatment of this disease has obtained such wide and deserved acceptance. A large part of his professional life was occupied in advising banks, corporations, and steamship companies doing business in the East and in this capacity a great many candidates for posts abroad passed through his hands and his skill in this special branch of medicine was remarkable.

From his earliest professional life Dr. Thin was a diligent student of the microscope and even when health began to decline and age to creep on he still took a deep interest in the subject. In all his work there was the impress of patience and thoroughness. His intellect was strong and incisive. If his manner appeared to some distant and reserved it was simply because he was a sceptic in the best sense of the word and was naturally incapable of taking anything on trust that admitted of proof. But below this cautious manner there was a thoroughly high-minded personality, perfectly honest and just. He was a man with few close friends but when he did give his confidence it was lasting For more than a year his health had failed and he was compelled to give up all professional work in the hope that rest might enable him to live. But in December he became steadily worse and he died at Nice on Dec. 27th of last year.

DAVID THOMSON PLAYFAIR, M.D., L.R.C.P. & S. Edin.

By the death of Dr. David Thomson Playfair, which occurred suddenly at Bournemouth on Feb. 1st, the medical profession in Bromley, Kent, loses one of its best-known members. Dr. Playfair was the elder son of the late Rev. David Playfair of Abercorn, N.B., where his early years were spent. He was educated chiefly at the old collegiate school, Edinburgh, and at Blair Lodge. His medical education he received at the University of Edinburgh under Tait, Crum Brown, Turner, Spence, Lister, and other distinguished men.

On leaving Edinburgh he spent some time in Paris and also at Leipsic and Tübingen. After qualifying he resided as assistant physician at Sunnyside Asylum, Montrose, and afterwards at the Royal Albert Asylum, Lancaster, and he at one time thought of taking up the study of mental disease in a special way, but a favourable opportunity of entering a practice at Bromley presented itself and he settled down there, where he spent the remainder of his life. Dr. Playfair was for some 24 years in Bromley, being at first in partnership with Messrs. Hughes and Willey, and for the last 17 years with Dr. John Scott who was his partner until his death. In local politics he took no part but in matters connected with his profession he always took a very keen interest, as well as in those associated with science or with music. He was on the staff of the Bromley Cottage Hospital almost since his first going to Bromley and on the committee of that institution for many years. He was for a long time a member of the Bromley Naturalists Society and he was one of the founders, and for some years president, of the Bromley Musical Society. He always kept up his early love of botany and possessed a very large and complete herbarium. He was a good photographer and a clever mechanic, as well as an enthusiastic sportsman, having considerable skill both with rod and gun. As a physician his well-trained powers of observation stood him in good stead and gave him a keen insight both into disease and into human nature and he was very successful both in diagnosis and in treatment.

As a surgeon he was a rapid and skilful operator, his having long been addicted to many mechanical pursuits giving him much facility in the manipulative side of the surgical art. Dr. Playfair was twice married, his first wife dying on March 31st, 1894, and on April 30th, 1902, he was married to Miss Annie Seaton Winton, only daughter of Mr. Edwin W. Winton of Etherton-hill, Speldhurst, near Tunbridge Wells. Dr. Playfair had been in failing health for some months, heart trouble—complicated by an attack of appendicitis—having kept him entirely to his house until a very few weeks before his death, when he went to Bournemouth in the hope of regaining strength. During the day of Feb. 1st he had been much as usual but shortly after retiring to rest he had a sudden attack of heart failure and passed away quietly in a few moments. He was buried at Edinburgh on Saturday, Feb. 6th, there having been a service in the Bromley parish church on the previous evening, at which the large attendance of all classes—the church being full to overflowing—attested to the esteem in which the deceased was universally held.

GEORGE COLVILLE MILLIGAN, M.A., M.B., C.M. ABERD.

REGRET for the death of Dr. G. C. Milligan will be felt by a wide circle of his friends both in the British Isles and in Switzerland, where he was assistant at one time at the Belvedere Sanatorium, Davos-Platz. The deceased gentleman had not been in good health for some considerable time, but up to within a few days of his death, which took place on Jan. 23rd, he was visiting his patients and following his profession with zeal. Dr. Milligan was the eldest son of the Rev. P. Milligan, minister of Guthrie. He received his education at the University of Aberdeen, where he graduated M.A in 1884. In 1888 he took the M.B. and C.M. degrees of his university and subsequently went to Forres as an assistant to Dr. G. L. H. Milne whose practice he afterwards acquired. His *clientèle* was a large one and in addition to his private practice he held the post of medical attendant at Cluny Hill Hydropathic Establishment and was surgeon at Leanchoil Hospital, Forres. Ill-health compelled him to spend his winters in Switzerland and for many years he practised alternately in Scotland and at Davoz-Platz. Dr. Milligan was held in the highest esteem and regard by all who knew him. He was a keen sportsman, took an active interest in golf, and was enthusiastic in the national game of cricket, besides being a capable exponent of tennis. In all of these games he took more than an academic interest for he recognised their value as agents in the maintenance of health and participated in them with the knowledge of an expert. He leaves a young widow and one son to mourn their loss, for whom the deepest sympathy will be felt.

DUNCAN CAMPBELL LONGDEN, M.B., F.R.C.S., D.P.H. EDIN., M.R.C.S. ENG.

Dr. D. C. Longden died in London at the house of his brother, Mr. E. W. Longden, on Jan. 18th, at the early age of 37 years. His medical education was obtained in Edinburgh and while a student he gained various prizes and honours, including in 1886 the gold medal scholarship in anatomy at the Royal College of Surgeons. He graduated at the University of Edinburgh as M B. and C.M. in 1887, and was appointed by Dr. J. Macdonald Brown to be senior demonstrator of anatomy at Surgeons' Hall. Thenceforward he devoted his entire energies to anatomy and his labours at Surgeons' Hall not only won for him the esteem of his colleagues but the admiration of the numerous students who attended the classes during the succeeding three years. In 1890, owing to ill-health, he was reluctantly compelled to resign his position, and at a smoking concert given in his honour he was presented by the students with an address and a gold watch. In 1891 his health improved considerably and for the ensuing two years he lectured on anatomy in the School of Medicine for Women in Edinburgh until he was obliged by a recrudescence of chest symptoms finally to abandon teaching and to go abroad. In 1894 he proceeded to St. Helena, where he resided for six months. During the next five or six years he acted as a surgeon in the British India Steamship Company's Service and in that capacity made frequent passages to India and to the Cape of Good Hope. In 1900, while at the Cape, he obtained permission to leave his ship and was appointed medical officer for the Boer refugee camp at Barberton, Transvaal. He remained there until March, 1903, when he returned to England. Although gradually becoming weaker and weaker he was nevertheless able to appear at Buckingham Palace in November last when he received the Transport Service medal at the hands of the King. The funeral took place on Jan. 21st at Kensal-green Cemetery. Dr. Longden was a man of singular gentleness of disposition, a brilliant teacher, a sound anatomist, and a faithful friend.

WILLIAM HUTCHISON, M.D. ST. AND., L.F.P.S. GLASG.

Dr. William Hutchison, who died at his residence at Brightlingsea in Essex on Jan. 32rd, saw a good deal of military life in his early days. When he became qualified as L.F.P.S. Glag. in 1854 the Crimean war was in progress. Having volunteered for medical duty he served as a civil surgeon on the medical staff and did much useful work in attending the wounded. He was present at the battles of Alma, Inkerman, and Balaclava, as well as at the siege and fall of Sebastopol. After the war he spent some time in long sea voyages. Returning to England he practised in Loughborough, Leicestershire, for many years and was on the staff of the Loughborough Hospital for a long period. In 1862 he graduated as M D. at the University of St. Andrews. During the Franco-German war in 1870 Dr. Hutchison and his wife took an active part in the collection of clothing and money in Loughborough on behalf of the Red Cross Society, which was at the time sending ambulances and stores to the continent for the relief of the wounded. An account of a case of stricture of the rectum under his care in the Loughborough Hospital was published in THE LANCET of June 1st, 1878. About 13 years ago he disposed of his practice in Loughborough and since that time lived mostly at Brightlingsea where he died. Some of his family, however, are resident in Loughborough and it was in the cemetery there that the funeral took place.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Paul Grassnick, formerly Sub-director of the Kaiser Wilhelm Academy for Military Surgeons. He served with distinction in the Franco German war. He retired a short time ago with the rank of major-general. His age was 69 years.—Dr. Conrad Clar, extraordinary professor of balneology and climatology in Vienna, at the age of 59 years.—Dr. Peypers of Amsterdam, who founded the journal *Janus*, which is devoted to medical history and geography.—Dr. Gustav Neusser, a Cracow alienist.

RESEARCH FELLOWSHIP AT ST. JOHN'S COLLEGE, OXFORD.—This College will shortly proceed to elect as an Ordinary Fellow a person whose attainments in literature, science, or art shall in its judgment qualify him to be a Fellow and who shall undertake, if required, to perform some definite literary, scientific, or educational work in the College or in the University or (under the direction of the College or the University) elsewhere. Applications (together with any evidence of qualification which the candidate may desire to submit) should be sent to the President before Feb. 20th and may include a statement of the work which the candidate proposes to perform if required.

providing more of these unobstrusive baths and washhouses for the Manchester slum dwellers. The Bishop (Dr. Knox) referred to Birmingham and said that he had the satisfaction of knowing before he left that the work there, begun on the Manchester model, was extending. "An authority acknowledged to him that it was one of the best things done for the improvement of the health of the city." He thought there were great advantages in the voluntary superintendence of ladies over paid visitors. "They approached the work from a point of view which the purely official mind could not grasp, the point of view of one who longed to raise human nature to a higher plane and who was not bound by considerations of what the ratepayers would think of this or that expenditure." Both the Ladies' Health Society and the Sanitary Association could do more effective work with more funds and more helpers.

LITERARY INTELLIGENCE.—On the 15th of this month Messrs. Kegan Paul and Co. will issue a new monthly journal entitled "Our Hospitals and Charities Illustrated." It will endeavour to awaken and to stimulate interest in the work of our hospitals and charities, particularly amongst men and women of moderate income It is to be essentially a journal for the public and all matters of controversy and technicality will be avoided It is hoped that it will assist in preparing fresh ground for successful appeals on behalf of our hospitals and charities. The price will be 3*d.* monthly.—The fifteenth annual issue of "Burdett's Hospitals and Charities, the Year book of Philanthropy and Hospital Annual," will shortly be published by the Scientific Press, Limited, 28 and 29, Southampton-street, Strand, London, W.C.

GUERNSEY NATURAL SCIENCE SOCIETY.—The introductory lecture at the commencement of the current session of this society was delivered by the President, Dr. John Aikman, the subject of discourse being Some Aspects of Light He showed that in proceeding from the red end of the spectrum to the blue end the visible rays displayed progressive increase of refrangibility and of wave frequency. The heating power of the red rays, the actinic effect of the blue rays, and some of the properties of the ultra violet rays and of Fraunhofer's lines were also explained. The discovery of radium and the phenomena of radio-activity manifested, though in a less degree, by other substances was touched upon, after which Dr. Aikman discussed the *rationale* of Professor Finsen's application of light in the treatment of disease.

COOKERY AND FOOD EXHIBITION.—The Universal Cookery and Food Association is holding its fifteenth exhibition at the Royal Albert Hall in April next from 26th to 29th inclusive, under the distinguished patronage of Her Majesty the Queen, the chairman of the council being Mr. J. C. Buckmaster and the chairman of executive Mr. A. Judah. Competitions for children, teachers, soldiers, and others, and demonstrations by experts will be of daily occurrence, while professional chefs, confectioners, and bakers will be represented by their best efforts in the respective departments. Exhibits also of every description of simple dishes will be showr [illegible] sections. Valuable prizes, [illegible] trophy, and cash awards ar[illegible] comprises food products and commercial exhibits covering a wide range of subjects of interest to caterers, as well as to the general public

CENTRAL MIDWIVES BOARD.—At a meeting of the Central Midwives Board held on Jan. 28th, Dr F. H Champneys being in the chair, letters were read from Mr. E Hastings Tweedy, the Master of the Rotunda Hospital, Dublin, and from Professor J. W. Byers, physician to the Incorporated Belfast Maternity Hospital, calling the attention of the Board to the practical impossibility of pupil midwives trained in these institutions complying with the requirements of Section O. The answer of the Board has already been recorded in THE LANCET of Feb 6th, p. 401, and in our present issue (p. 457) will be found the correspondence between Mr. Tweedy and the secretary of the Board. After consideration of applications for certificates the names of 1040 women were passed under Section 2 of the Act and ordered for entry on the Roll. Of this total 269 claimed as holding the certificate of the Obstetrical Society of London, 14 that of the Rotunda Hospital, 26 that of Queen Charlotte's Lying-in Hospital, 14 that of the Glasgow Maternity Hospital, 14 that of St. Mary's Hospital, Manchester, two that of the Liverpool Lying in Hospital, one that of the Edinburgh Royal Maternity Hospital, one that of the City of London Lying-in Hospital, and 699 were admitted as having been in *bonâ-fide* practice for one year prior to July 31st, 1902.

NEWCASTLE-UPON-TYNE LYING-IN HOSPITAL.—The annual report of this institution has just been published and it shows that the progress which commenced in 1901 has been more than fully maintained during the past year. The total number of cases has increased from 380 in 1902 to 674 in 1903. The committee reports that the hospital has been recognised by the Central Midwives Board as a training school for midwives.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. W. P. Johnstone, M.B., C M. Edin , J.P , Witwatersrand, South Africa, has recently been presented by the officers of the 1st Battalion Gordon Highlanders with a silver cigarette box suitably inscribed. Prior to this presentation he received a silver teapot, also suitably inscribed, from Captain Shearman and Captain Poole of the 10th Royal Hussars, and several cases of surgical instruments from Captain Peck of the Royal Horse Artillery. Dr. Johnstone formed, and was in charge of, the temporary hospital at Maraisburg during the South African war.

DONATIONS AND BEQUESTS —By the will of Mr. Edmond Dresden pictures and portraits are bequeathed to the Children s Hospital, Great Ormond-street, to be hung in the wards, as well as a sum of £25,000 for the maintenance of beds to be called the "Dresden Cots," which are to be contained in a ward to be called the "Dresden Ward." Middlesex Hospital, St Mary's Hospital, the Royal Free Hospital, the Hospital for Consumption, Brompton, and Queen Charlotte's Lying in Hospital each receive a donation of £5000 Under this will a sum of £250,000 will be available for charitable purposes and each of the hospitals mentioned will, under certain conditions, receive further legacies.

SOME NOVEL PATENTS.—An American inventor has patented "an apparatus for disinfecting paper money, consisting of two endless aprons travelling in holding contact with each other, the contacting portions moving in the same direction, a series of moistening, feed, and heating rollers, around which the endless aprons travel, and means for applying the liquid disinfectant to the bills, as they are fed between the moving endless aprons, to be subjected to the action of the vaporised disinfectants" Another inventor has patented a comb for applying liquid to the scalp; it has a hollow back and teeth and the fluid issues from perforations in the points of the latter. Specifications and drawings of both of these contrivances are given in the *Official Gazette* of the United States Patent Office issued on Jan. 26th.

THE ANNUAL DINNER OF THE PAST AND PRESENT STUDENTS OF THE DURHAM COLLEGE OF MEDICINE —This dinner was held in the County Hotel, Newcastle-upon-Tyne, on Jan 30th, Mr. Frederick Page, professor of surgery, being in the chair. The principal guests were the Warden of the University, the Earl of Durham, the President of the College of Medicine, Professor R Howden, and others. The dinner was well attended by past and present students, about 130 being present. The Earl of Durham, who is a great favourite with the students, in reply to the toast of "Our Guests," made a very interesting and amusing speech. He said that he was sure the college authorities all desired free trade in brains. They did not mind how much of the raw material was dumped down in the College of Medicine; he was sure that it would be turned out as a highly finished article and that in future they would be able to polish off their fellow creatures in the most scientific manner possible.

T [illegible]

on t [illegible] Plymouth before the Teachers Guild Dr. F G. [illegible] discussed some questions which ought as much as possible to be impressed on the minds both of teachers and of the rising generation under their charge. He said that the Education Department had confined itself mainly to regulations intended to insure the physical well being of children, had drawn up building rules which, he understood, were often disregarded, had provided for the exclusion of children or for the closing of schools during epidemics, and had sanctioned a course of physical training conducted according to a specified system. It was obvious, however, that there were many respects in which regulations excellent in themselves and officially recognised as authoritative could only produce their anticipated effect when the teachers were really convinced of the practical value of such injunctions. The general hygiene of schools, and especially the ventilation of class rooms, required much attention and the system followed by the teacher constituted an object lesson which might be influential in forming the habits of the children. Teachers ought therefore before receiving their certificates to be required to show some acquaintance with the elements of hygiene and with the laws governing the spread of infectious diseases.

NEWCASTLE-UPON-TYNE CHILDREN'S HOSPITAL.—The annual court of governors was held on Feb. 2nd in the hospital. The amount of work done was about the same as in the previous year. The out patient department having become inadequate considerable additions to it are in course of erection and the fund for these extensions now amounts to £6207. During the past year the hospital has been most unfortunate in losing by death four of the most important and valued vice-presidents who were also the most generous donors to the hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Physical Condition of Children.

ON a date which has not yet been fixed Sir JOHN GORST will move that a select committee be appointed to inquire and to report as to the best method of keeping a record of the physical condition of children attending schools which are aided by Parliamentary grants.

Cancer Returns.

Mr. WEIR has been interesting himself in the question of the registration of cancer cases in India and he proposes to ask Mr. Brodrick whether the Indian Government has yet arranged to have such cases recorded separately in dispensary and hospital returns.

Private Members' Bills.

About 40 Private Members' Bills have been read a first time in the House of Commons this week. Two of the number affect the medical faculty, one being General Laurie's "hardy annual" for the amendment of the Medical Act of 1886 and the other the Revaccination Bill standing in the name of Sir John Batty Tuke. Mr. Long, on behalf of the Government, has intimated his intention to bring in a Bill to amend the Public Health Acts.

HOUSE OF COMMONS.

FRIDAY, FEB. 5TH.

Arsenical Poisoning.

Sir CUTHBERT QUILTER asked the President of the Local Government Board whether his attention had been called to the confirmation by the Royal Commission on Arsenical Poisoning of the opinions expressed in the Minority Report of the Beer Materials Committee issued five years ago, prior to the outbreak of the beer poisoning epidemic, that legislation or other provision was necessary to prevent the use of deleterious substances in the manufacture of beer and that a court of reference, as recommended by the Committee on the Adulteration of Food Products (a recommendation since endorsed also by the Food Preservatives Committee), should be established for fixing standards of purity for the purposes of the Sale of Food and Drugs Acts; and if so, whether he would say what action it was proposed to take to give effect to the recommendations of the Royal Commission, more especially as regards the protection of the public against the use of injurious ingredients in beer and the fixing of a standard of purity.—Mr. LONG replied: I had, before the issue of the report of the Royal Commission on Arsenical Poisoning, had under consideration the expediency of promoting legislation with a view to the constitution of a court of reference for the decision of certain scientific questions in relation to food of the kind referred to in the question and I had been in communication with the Board of Trade and the Board of Agriculture on the subject. I am continuing to give attention to the matter, but having regard to the large and important recommendations of the Royal Commission on Arsenical Poisoning I think it will be necessary that a conference should be held of representatives of the Government departments concerned before a decision as to the course to be adopted can be arrived at.

JONES.—At his residence, 2, Vauxhall Bridge-road, Feb. 3rd, 1904, Robert William Jones, M.R.C.S., L.R.C.P., &c., formerly of St. Thomas's Hospital.

SCOTT-WATSON.—On Feb. 8th, at Sidlands Lodge, Sidmouth, Charles Scott-Watson, M.R.C.S. Lond., aged 49 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

OVERCROWDING ON THE UNDERGROUND EAST-END TRAINS.

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET I once saw the statement that in the journey from Charing Cross to East Ham by the new connexion of the Underground with the London, Tilbury, and Southend Railway it was a common experience to find about 18 or more persons in a compartment who, besides enduring great discomfort, ran perilously near to being suffocated. Since then the overcrowding seems to have become worse. In one of the morning papers a correspondent recently wrote that "train-packing is becoming a fine art on the District Railway East Ham trains." I understand the object of a fine art to be to give pleasure, but the train packing on the East Ham trains gives decided pain. I hardly expect an international medical journal to devote more space to the complaints of an unimportant section of the London public, and yet there are a good many of us daily inconvenienced, while the public health aspect of the matter seems to me, a prejudiced sufferer, not without importance. A few days ago 32 of us rode in one compartment. Each compartment was built to seat ten people and even that not too comfortably, as many of the compartments are narrow, and in the most favourable circumstances the third-class passenger knocks knees with the passenger opposite. This railway serves to some extent what is, perhaps, the poorest part of London, so that certain of the passengers are evidently and necessarily uncleanly in their persons because of the character of their work. Others wear clothes suitable to their superior work and find the contact very annoying. No accusation of snobbishness can be founded upon this. A clerk must wear garments which are not improved by being closely pressed against oily or mucky corduroy. The breath, again, of some British workmen is highly charged with the odours of stale beer and rank tobacco. I do not despise the workmen because of this, but I ask you, Sirs, to commiserate with the less robust passenger who is not partial to those spicy flavours, for on the London, Tilbury, and Southend Railway he must perforce grin and bear the fumes, because the propagator of them is wedged within six inches of his mouth.

The way people are allowed to crowd into the carriages of this line in the busy hours of the morning and evening is nothing short of a standing disgrace to London and, though knowing nothing whatever about it, I doubt if troops will be conveyed from Moscow to Mukden in circumstances of greater hardship. I dare hardly imagine what would be the direful consequences in case of a collision on this mainly underground line. Many of the passengers are fastened in like sticks in a bundle of firewood and would be scarcely able to lift a finger to attempt to save themselves. Let the influential shareholders be wise in time and have a care and contemplate the possible amount of the damages they may be called upon to pay. It does not matter whether a passenger pays second- or third-class fare—he is suffocated and jammed just the same. A few of the first-class carriages are kept locked sometimes. Why this disgusting and appalling overcrowding should be permitted on this railway and on some other railways, and should be forbidden in omnibuses and tramcars travelling in open streets where there is considerably more fresh air, is beyond comprehension. A railway company should no more be allowed to take money for accommodation which is not provided, and which the company knows is not provided, than any ordinary trader is allowed to take and to keep money for goods that he cannot supply.

Is there not a public health side to this matter which will encourage you to call further attention to a scandal? The risk of infection by inhalation of germ-laden breaths is surely much exaggerated when 32 passengers ride in a box improperly constructed to hold ten.

I am, Sirs, yours faithfully,
Feb. 11th, 1904. SARDINE.

*** Our correspondent has our sincere sympathy. A railway company seldom listens to isolated complaints from however many points such complaints reach them. What is wanted is combination among the passengers to insist upon the reform of a condition of affairs which, as described by our correspondent, must be insanitary. —ED. L.

A NEW FORM OF SCABIES.

WE have received the copies of an interesting correspondence which has taken place between the East Suffolk County Education Committee and Dr. C. W. Low, medical officer of health of the Stowmarket urban and rural districts. The first letter informs Dr. Low that "scabies is very prevalent in the B—— school and he is requested to send" an order for the necessary closing of the school whilst the disinfection of the buildings is proceeding." Dr. Low very properly wrote back to say that he could not give an order for closing the school but could only recommend the issue of such an order, if he thought it to be necessary, to the rural district council, in which body alone such discretion is vested. He added, however, that he had made a careful investigation at the school where scabies was stated to be prevalent and had satisfied himself that no single case of the disease had occurred there. On inte viewing the mistress of the school he had learnt from h that three children only had been absent by reason of the allege outbreak of scabies and that no medical evidence of the nature of th disease had been obtained. A local druggist had given a ce tificate to a parent of the absentee children, which certificat the parent refused to show or to surrender. Dr. Low accordingl visited the home of the absentee children, examined them, and coul detect no trace of the alleged disease. He then, in the interests the Education Committee, instructed another medical man to vis the children in order that a proper medical certificate might obtained as to the nature of their ailment. This was done and th medical certificate showed that the children were "suffering fro a little dry, scaly eczema. ...... I cannot find a trace of scabi even with a very strong glass." Dr. Low closes his com munication by requesting the education committee to pa certain out-of-pocket expenses and a fee of one guinea to him for services not involved in the duties of his office. Then follows copy of the druggist's letter, in which the word "scabies" is no used, the lay distributor of medical certificates, confining himself t the opinion that "as the skin affection your boys are suffering fro is of a contagious nature I think it is your duty not to send them t school until quite cured." Lastly comes a letter from the Ea Suffolk County Education Committee, very properly acknowledg Dr. Low's services and admitting that fees are due to him and to th second medical man who examined the children.

The story is very instructive as showing the trouble that can arise to a community by the habit that certain druggists have o assuming medical functions. Here is a druggist who is shown tha very ordinary condition, a little dry eczema of the scalp, and a once certifies it as contagious skin disease, during the progress o which the patients must not be sent to school. From this fact arises a report that scabies is prevalent in the school and on this follows the natural and reasonable suggestion from the local authority that the school should be closed. And so because a druggist chooses to make an excursion into medicine the education of the children of the district comes near to being dislocated. The functions of a pharmaceutical chemist do not include the diagnosis and treatment of cutaneous, or other, diseases or the giving o *medical certificates.*

SANITATION IN CUBA.

IN an official report which is published by the *Archives de Médecine Navale* for December, 1903, Dr. Pungier of the French navy gives a very interesting account of the sanitary ameliorations which have resulted from the American occupation of the island of Cuba. A few years ago, he says, Santiago had a most unenviable reputation for insalubrity. Scavenging was unknown, there were no drains either on the surface or beneath it, household refuse thrown out of doors putrefied in the streets, and in every hollow there was a stagnant pool. Close to the town on its western side a vast swamp exhaled foul emanations and afforded a breeding place for myriads of mosquitoes. Malaria reigned supreme and yellow fever was permanently established. The annual mortality, according to Dr. Caminero, was at the rate of 34 per 1000. The American soldiers had no sooner taken possession of the place than at once the medical officers began to remedy this disastrous condition of things. The measures which they adopted were sufficiently drastic and necessitated the expenditure of 60,000 dollars a month. Live stock of every description was banished from the town or, as Dr. Pungier expressively puts it, "dogs, poultry, and cattle were suppressed." Where it was possible to do so ponds were filled up or drained, while swamps too extensive to be dealt with after this fashion were deluged over and over again with petroleum. Pending the construction of a network of sewers, for which a contract, to be completed in five years, was given to a local company, a system of conservancy was organised for the daily removal of filth. Lime-washing and carbolic acid sprinkling were freely employed inside the habitations as well as outside and in a word all the latest innovations for insuring the public health were carried out. The beneficial effects of these measures, which were supplemented by judiciously applied regulations for the treatment and control of epidemic diseases, were not long in making themselves felt. Yellow fever disappeared as if by magic, the last case which occurred having been noted in December, 1899. Paludism has diminished to a wonderful extent; Dr. Pungier was assured by a competent authority that the only cases now observed took place amongst workmen who are employed on the railway to Havana. From 34 per 1000 the mortality has fallen to less than 15 per 1000 per annum. Instead of being an exceptionally insalubrious town Santiago may now be called one of the most healthy in the world. In Havana, which was also inspected by Dr. Pungier, the Americans, he says, have succeeded in accomplishing marvels. Like Santiago, the capital of Cuba was formerly the home of paludism and yellow fever, its sanitary condition, owing to the remains of its extensive fortifications which shut out the sea breezes and excluded light and air, being, if possible, more deplorable than that of the former town. The whole of the obstructive ruins has now been removed to make way for verdant lawns and spacious tree-planted promenades and boulevards. The existing sewers have been thoroughly overhauled but can only be regarded as a makeshift pending the installation of more up-to-date constructions. In dealing with the sanitation of private residences in Havana the Americans, says Dr. Pungier, have exhibited a rigour which was absolutely draconic. Rich and poor were treated alike; 22,200 houses were cleansed and put in order from basement to garret, water-closets according to a uniform pattern, with ventilating shafts opening above the roof, being established in each Soiled hangings and unclean furniture were pitilessly thrown into the streets by the sanitary agents, but the results have been most brilliant. During the 11 years from 1890 to 1900 the average annual number of deaths in Havana from yellow fever was 467, in 1901 there were five deaths from that disease, and in 1902 there were none. In 1899 the deaths due to malaria numbered 909, in 1900 the deaths from that cause amounted to 325, in 1901 to 151, and during the first ten months of 1902 to 73. In conclusion Dr. Pungier describes the Quinta de Salud Covadonga hospital for 500 patients. "I have inspected," he says, "the Charity at New Orleans, the Johns Hopkins at Baltimore, and the New York and the St Luke's in New York, but none of these hospitals gave me the same impression of comfort and intelligent luxury or anything like it as I felt when visiting the new hospital at Havana."

THE CONTROL OF THE MANUFACTURE OF AERATED WATERS

In a leading article in The Lancet of July 4th, 1903, p 40, we dealt with a very important report presented to the London County Council by Dr. W. H Hamer upon the conditions under which aerated waters are manufactured. A resolution was ultimately adopted by the Council in favour of forwarding a copy of this report to the Local Government Board, together with an expression of opinion that legislation was desirable in order to secure the manufacture of aerated water under sanitary conditions. The Council having received no intimation from the Local Government Board as to whether it was its intention to promote legislation in the direction indicated decided at a recent meeting again to communicate with the Local Government Board with the view of urging upon it the importance of the matter and the desirability of introducing a Bill upon the subject in the present session of Parliament.

THE LAW UNION AND CROWN INSURANCE COMPANY AND ITS MEDICAL EXAMINERS.

We have received further communications from medical men to whom the district managers of the Law Union and Crown Insurance Office have suggested that they should examine persons proposing to insure their lives for less than £200 at a reduced fee of half a guinea One medical man informs us that he has refused to comply with the view of the district manager and has expressed his surprise at the innovation. Another correspondent makes the cynical suggestion that he should take the reduced fee and give the company reduced service for it. For a fee of half a guinea he considered that the company ought to be satisfied if he half examined the proposer. This gentleman has logic on his side. If the company hucksters it cannot complain that huckstering is practised against it In trade if a person is prepared to pay only half he can purchase only half, and the Law Union and Crown Insurance Company has approached medical men in a trade spirit Of course, no member of our profession would sign a docu- [illegible] been examined into but whose chests and urines remain unassayed The retaliation, though impossible, is, as we have said, logical

CLUB PRACTICE MEDICINE.

To the Editors of The Lancet.

Sirs,—If Hunyadi Janos water be prescribed by a club medical officer for his patient to take it for some time is such water considered medicine or not? I am, Sirs, yours faithfully,

Feb. 9th, 1904. Inquirer.

*** We cannot, of course, tell what views the committee of the club in question would hold on the point, but the water named certainly is a medicine —Ed. L.

CHILDREN AND FIRE.

Notwithstanding the frequent occurrence of inquests on children who have been the victims of flannelette numbers of people are sceptical as to its dangers. But they are chiefly well to-do people who do not leave their little ones where the grate is without a fireguard while there is no one to see to their safety. It is happily but seldom that such an object lesson occurs as in Manchester the other day. Three inquests were held on Jan 23rd by the city coroner on three children, each two years of age, in three different parts of the city, who were burnt to death from their flannelette clothing catching fire One little girl was acting as nurse and rocking her baby brother close to the fire, where there was no guard The mother thought a cinder had set the child's flannelette nightdress on fire. The other cases were from playing with fire, which has an irresistible fascination for most children Mr. E A Gibson, the coroner, said that in all probability they would not have died if they had not been wearing this dangerous material. "It flamed up like gunpowder and it was almost impossible to extinguish the blaze before great injury had been done." It is cheap and warm, which of course makes it popular, but it might easily and inexpensively be rendered non inflammable, and it is quite time that the authorities should prevent its sale unless this is done. There is such a material on the market that goes by the not very attractive name of "Non Flam," but we fancy that its sale is small compared with that of the ordinary variety. Mr. Gibson showed some to the jury and applied a light to samples of each, the flannelette immediately burned into a blaze, while the other was proof against the light. As he said to the jury, "It was perfectly heartrending to have a list like that with three small children all burned on the same day from the same cause." Apart from the question of inflammable dress materials the provision of fire-guards when children are left alone in rooms where a fire is burning should be enforced by law.

THE STANDARDISING OF SEWAGE

We understand that with the approval of the Council of the Sanitary Institute Mr. Scott Moncrieff's sewage testing apparatus can now be seen in the Parkes Museum. The apparatus has been designed for the purpose of obtaining exact information upon which to base bacterial sewage disposal schemes, particularly as to (1) the depth of filter required to produce the necessary standard of purity in the effluent, (2) the quantity of air necessary for the life processes of the organisms in the filter, (3) the correct rate of flow per unit of filter-bed surface in order to obtain the best results; and (4) the best period of rest between each discharge to prevent gelatinous growths in the filtering material.

"FILTHY LUCRE."

Our annotation under this heading in The Lancet of Feb. 6th, p 381, has attracted considerable attention and we have received some correspondence upon the subject in which the writers cordially approve of our suggestion that in those places where banks receive a large number of coins in bulk which are subjected to the defilement of fish, meat, and other more or less dirty traffic, such coins should be cleaned in some simply designed washing apparatus before being returned to circulation. We understand that at a certain bank near Billingsgate Fish Market some such cleansing apparatus is adopted Several of our correspondents mention an invention of their own for this purpose. We cannot consider the merits of these or advise as to whether their apparatus would bring any substantial reward to the respective inventors. They should consult a respectable patent agent or communicate with the banks We may repeat, however, that if a cheap and handy machine were devised and adopted for rapidly washing and scrubbing coins at the bank it would amount to a great public benefaction and would be a step of the highest sanitary importance.

A JURY OF MATRONS

It is rare nowadays to see empanelled a jury *de ventre inspiciendo.* From very ancient times—long before the advent of the registered medical practitioner—it has been the law that when a woman sentenced to death pleads pregnancy as a bar to execution, a jury of matrons or discreet women shall be called together to examine her and to advise the judge whether or not she is "quick with child" In latter days this procedure has dropped into disuse and the evidence of medical men has been substituted. It was [illegible] revived at the last [illegible] of the prison [illegible] and having [illegible]

FURTHER OBSERVATIONS ON THE VALUE OF GARLIC AS A TREATMENT FOR TUBERCULOSIS.

To the Editors of The Lancet.

Sirs,—Having read the most interesting article by Dr. Giulio Cavazzani upon the action of garlic as a prophylactic in cases of tuberculosis which appeared in The Lancet of Jan 9th, p 90, and in which he expresses the hope that it may lead to a discussion upon the subject, I beg that you will allow me to record a brief account of my experiences with it as a remedy in almost all forms of tuberculosis, as I believe the results obtained from it are more encouraging than from any other treatment yet brought forward

In the *Medical Press and Circular* (Dublin, June 4th, 1902) I published a paper giving some of my experiences with garlic as a remedy for tuberculosis in its various forms After this publication I was made aware that Dr. G V Poore of University College Hospital, London, had already recommended that garlic should be taken internally in pulmonary tuberculosis in his book "Nervous Affections of the Hand and other Studies" (published by Smith, Elder, and Co, 1897), p 275, also that Dr Cavazzani had recommended it to be similarly used in a publication in a foreign journal in 1901. The fact of the discovery of its utility being made in three places so remote from one another and quite independently is in itself good evidence, I think, of its virtues in this disease [illegible]

When I first commenced to use [illegible] tuberculosis, now something over [illegible] internally with varying success I [illegible] in some cases, usually very early cases or old standing fibroid cases, [illegible] cases showed little or no improvement. I [illegible] nal treatment, employed an [illegible] to the sponge of an inhaler [illegible] ey Yeo for use with antiseptic [illegible] advised the inhalation to be [illegible] daily. I have had some very [illegible] treatment and I can strongly [illegible] t is suited to similar cases to those above mentioned and with such will give most satisfactory results, yet it leaves much to be desired.

Since the publication of my paper in 1902 I have further discovered that garlic when applied locally is freely absorbed by the skin and penetrates to the deeper tissues, and I have had very gratifying results from the application of poultices of freshly pulped or pounded garlic over diseased areas, and I now employ these three methods combined in pulmonary cases with much success. Garlic when applied in this manner acts as a strong blister, the various varieties of it being of widely different strengths. Some varieties will blister in from four to six hours, whilst others take 24 hours or even longer.

It may be advanced that its beneficial effects when applied in this manner are due to its action as a blister, whilst also a certain amount of inhalation takes place. I think, however, it is absorbed by the skin, penetrating to the deeper tissues, as I have had remarkable success with it in cases where the inhalation had failed. Further, it is a most successful treatment when applied locally to any tuberculous lesion, such as a joint, tuberculous glands, &c., even though the skin be unbroken. The garlic when pulped or pounded and applied in this way appears to act more beneficially than the fresh juice. Cases of laryngeal tuberculosis if not very far advanced rapidly yield to the application of garlic either by gargle, or spray, or internal administration (or combined), accompanied by a poultice (or blister) of pulped garlic externally. It is an excellent treatment for lupus, and has the advantage that it can be applied to almost any part and over a very extensive lupoid area. Where it can be borne, a blister of pulped garlic is the best and most rapid mode of treatment, leaving it on three or four hours and re-applying in a few weeks, but it can be very efficiently treated with the fresh juice as I described in my paper in the *Medical Press and Circular*. This method has the advantage of not being at all severe but it is not nearly so rapid in its results. Garlic is a powerful germicide worthy of the careful consideration of bacteriologists and I have the strongest reasons for believing that a poultice of it applied over the seat of inoculation and also given internally will prevent the development of hydrophobia in a person bitten by a rabid animal. Dr. Poore in his work "Nervous Affections of the Hand and other Studies," p. 275, states: "The allyl compounds, such as allylic alcohol and oil of mustard, were shown by Koch to be strongly antiseptic and to have a remarkable power of inhibiting the growth of the bacillus anthracis." The farmers in this part of the country largely use garlic for the treatment of symptomatic anthrax, or "blackleg," in cattle and it is most effective.

The London Pharmacopœia formerly recognised garlic and some preparations of it are still officinal in the United States Pharmacopœia. It is described as being an antiseptic, an expectorant, a rubefacient, a diuretic, an antispasmodic, and a carminative. It contains a volatile oil—sulphide of allyl—to which it possibly owes its virtues. In an old work on therapeutics to hand, by J. Moore Neligan, M.D., 1851, he states that "garlic consists of an acrid volatile oil, fecula, albumen, and a saccharine matter; its medicinal properties depend on the volatile oil, which is heavier than water, of a yellowish colour, and a very penetrating odour; it is composed of six atoms of carbon, five of hydrogen, and one of sulphur" (Wertheim). He further recommends it as an excellent remedy in ascarides.

It is, of course, a very harmless substance (especially when diluted) in doses of the juice from half a drachm to one drachm two or three times daily. The addition of a little tr. lavand. co. and syr. simplex makes a fairly palatable mixture, the former masking the odour to a great extent. An infusion with milk is a favourite way of taking it. Half an ounce to one ounce of the bulb may be taken in this way daily.

One word of warning I must give regarding its use. I have found some surgeons (to whom I recommended the local application of garlic to tuberculous joints, &c.) fell into the error of injecting the fresh juice with a hypodermic syringe into the joints, &c. This should never be done, as owing to its vesicating action a violent inflammation will at once be set up. The local application should be altogether external but may be applied over a broken surface of skin and is not then much more severe than if the skin remains unbroken.

As some persons are rather susceptible to its blistering effects it is well not to leave the first poultice on more than four hours, after which it will be more easy to judge the length of time to leave the other poultices, which will require to be repeated frequently at intervals of three or four weeks to check the disease in the deeper tissues. The more severely it is blistered the more rapidly will the disease be checked, I think The blistered surface heals quickly under any ordinary oily application.

Such a powerful germicide as garlic, which is freely eliminated by the lungs as well as being freely eliminated and absorbed by the skin is, I think, a most reasonable one to use in the manner above described in such a disease as this under consideration, especially when one considers its harmless nature.—I am, Sirs, yours faithfully,

Kells, co. Meath, Jan. 25th, 1904. WM. C. MINCHIN, M.D. Dub.

DIET IN ITALIAN NAVAL HOSPITALS.

THE *Annali di Medicina Navale* for December, 1903, contain a long article on diet in the Italian naval hospitals by a medical officer of the first class V. Tiberio who is in charge of the pathological laboratory at Venice. There are, it would seem, four diets, named, respectively, entire, three quarter, half, and quarter. In all the ingredients are pretty nearly the same, the chief differences being in quantity. The question of the nutritive value of each diet is exhaustively treated comprehension being assisted by a series of very elaborate analytical tables. The main conclusion arrived at is that on the whole the several diets are fairly sufficient but that in some particulars they are not quite in accordance with the teaching of modern dietetics. It may be noted that all the diets include an allowance of wine which is thus specified: "The wine shall be of the best quality, made in Italy, red, genuinely pure, perfectly sound, free from acidity and mouldiness, without bad smell or bad taste of any kind whatsoever, pleasant to the taste, at least a year old, of not less than 12 degrees of alcoholic strength, and costing 40 centimes the litre."

THE VIAVI TREATMENT.

To the Editors of THE LANCET.

SIRS,—Can you tell me anything of the above? I had an idea I saw something about it in an old copy of THE LANCET but cannot find it. Was it dealt with in *Truth*? Some of my friends speak of it enthusiastically, hence my query. I am, Sirs, yours faithfully,

Feb 8th, 1904. SCEPTIC.

⁎ The Viavi Treatment is undiluted humbug and quackery. Our correspondent will find our opinion of it in THE LANCET of Jan. 17th, 1903, p. 211. *Truth* has also dealt with the matter.—ED. L.

◆

Batharon.—(1) The titles are synonymous and therefore (2) any one of them can be used. (3) A qualified medical man is qualified to practise medicine in the wide sense of the word in all its branches. It is not usual for a medical man to assume the designation of a specialist—ophthalmic surgeon or dentist, for example—without having undergone special training or enjoyed special opportunities, but we do not think such assumption would be construed by the General Medical Council as a professional offence.

Hon. S. Coleridge.—We do not intend to insert any letter from a correspondent who founds upon an obviously accidental and completely unimportant slip accusations of deliberate immorality. Mr. Coleridge can publish his letter elsewhere, can shriek that we have refused him a hearing, and can try to persuade people that we have acted from innate vileness. It is his own complete discourtesy that has decided us to ignore his communication.

Mr. H. A. Matheson.—The preparation about which our correspondent inquires was examined some years ago in our laboratory. It is a weak solution in water of sulphurous acid gas (SO$_2$).

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received *Sunday Sentinel (Milwaukee), Highland News, Cork Constitution, Evening News (Portsmouth) Cork Examiner, Aberdeen Daily Journal Aberdeen Free Press (Weekly) Westminster Gazette, West Cumberland Times Carlisle Journal, Dublin Evening Mail, Daily News Surrey Advertiser, Bristol Mercury Dublin Express, Morning Post Sanitary Record, Local Government Chronicle, Mining Journal, Hertfordshire Mercury, Burton Chronicle, Army and Navy Gazette, Medical Examiner, Knowledge, Illustrated Scientific News, &c.*

The chief lesson learnt from the cases was that the great bulk of the patients who suffered from head injuries became absolutely well, provided that they submitted to the necessary period of mental rest after the injury. The reason why so many hospital patients suffer from after-effects is that their treatment is too often too short. Those who suffered from remote consequences, those who gradually drifted, were the patients who returned to their business soon after the accident, before they had completely recovered. The history of these cases was often as follows. The patient said that he had a family to keep and must be at work, that he could not afford to rest; the dangers of his action were pointed out and were ignored. But he found that work required nearly twice as much effort as before and soon headache started and persisted. In about a month or so he consulted a medical man who perhaps said that he wanted a purge and a week-end in the country. But the headache returned and continued and so the case gradually drifted on, the patient being less capable of work, more depressed, slowly tending in the direction of melancholia, and sometimes dementia. Owing, then, to inadequate mental rest recovery is frequently incomplete after fractures of the skull and there is more than an element of truth in the popular idea that "a man is never the same after a head injury." In the out-patient department one is particularly struck with the number of cases applying for the treatment of symptoms consequent on these injuries; and in following up my own cases I was again and again met with the statement on the part of the relatives or friends that the patient "was never the same again."

The third series, the miscellaneous cases, includes a very important group which from their nature are not found in Series 1 and 2 I refer to those very mild forms of concussion in which loss of consciousness lasts a few seconds only or may be practically absent. Their importance has been emphasised by Sir William Bennett. Such cases are rarely admitted into hospital and the apparently trivial nature of the injury usually leads to entire neglect of treatment or to treatment of an entirely inadequate kind. Thus it comes about that grave consequences are more liable to follow the slighter forms of concussion the seriousness of which is overlooked than the more marked cases in which proper treatment is enforced.

Having thus indicated the general results of head injuries I shall now pass to their *effect upon the wage earning capacity* and then deal individually with the various symptoms which have come under my notice. The effect of head injuries upon the wage-earning capacity is a practical question and second to none in importance to the patient. Often he is the bread-winner of the family and we are asked how long it will be before he can return to his work and whether he will be able to do the same amount of work as before the accident. The question is of especial importance from the point of accident insurance, and again it is invariably raised in the litigation which often follows these injuries. I therefore took especial care to inquire into the effects of these injuries upon the patient's work, ascertaining how long they were kept from work and how much work they were able to do later. The results may be summarised as follows. The average interval between the date of the accident and the return to work after simple concussion was four and a half weeks, after cerebral contusion nine and a half weeks, and after a fracture of the skull or cerebral laceration 13 weeks. Only those patients who resumed work within one year are included.

Now as to the ultimate effect on the working capacity. Information upon this point is available in 86 of the fracture cases. 52 of these were doing the same work as before the accident and earning practically the same wages; 13 were doing lighter work, the average fall in wages in the labouring classes being from 27*s.* 6*d.* to 15*s.* a week; seven could only do very little work; eight had been compelled to give up their trade and take to other work; and six were totally disabled from work. Turning to the cases in which there had been loss of consciousness without apparent fracture we obtain the following results in 78 cases; 51 of these were working as well as before; 12 were doing the same work but said that they did not show the same interest and energy as formerly; six were doing lighter work; four could only do a little work; two had given up their trade; and three were totally disabled for work. In 59 per cent., therefore, of the cases in the first series and in 80 per cent in the second series the injury entailed no marked diminution in the working capacity or loss in wages.

Effects on Working Capacity.

	First series.	Second series.
No marked effects	52	63
Did lighter work	13	6
Only able to do a little work	7	4
Gave up trade	8	2
Totally disabled	6	3
Total	86	78

It will be noticed that in ten cases the patient had to give up his trade and to take to lighter or more suitable work. One of these was a builder and had fits; six had attacks of giddiness in ascending ladders or working at any height; of these six, three were carpenters, one was a bricklayer, and one was a painter; the sixth, a scaffolder, who had sustained a fracture of the base, was readmitted into hospital 16 months later with concussion and a fractured humerus, the result of a fall in an attack of giddiness whilst working on a ladder. Two cabmen had abandoned their cabs on account of giddiness, inability to stand hot weather, and especially owing to difficulty in remembering the names of streets. The last case was that of a police constable, to whom I am referring later.

We see, then, that diminution of the working capacity depends largely on the presence of certain disabilities following the head injury but partly on the particular trade or occupation which the patient is following. After severe head injuries patients are no longer fit to follow certain trades and occupations, especially those which involve ascending heights or which entail great responsibility. Thus the builder's labourer and the bricklayer can no longer with safety ascend ladders and work on scaffolding, the sailor cannot clamber in and out of the rigging, the fireman is untrustworthy at great heights, the engine-driver is no longer to be trusted, for his nerve might fail at any moment. These figures have dealt mainly with the labouring classes, but if we turn to the intellectual workers, to more highly educated patients, we find that the effect upon their work is distinctly more serious. A business man, for instance, who had sustained a severe head injury will not be fit to return to his business for several months and a long interval may elapse before he is capable of intricate calculations; the higher intellectual functions are always the last to be restored and the arithmetical faculty is an excellent example of this. Several of the patients I examined were city clerks and in these, as a rule, twice as long a period of rest was required as in those whose occupation involved purely manual work.

Beneficial effects resulting from head injuries are almost entirely confined to the imaginations of novelists. In real life they are comparatively rare. In this connexion I may mention a remarkable case seen last summer in which concussion caused *inhibition of chorea*. A boy, aged ten years, suffering from concussion, was admitted into St. George's Hospital under the care of Mr. A. Marmaduke Sheild. He had struck his head and had fallen backwards down some stairs. On admission there were marked bruising in the left occipital region and slighter bruising in the left frontal region. For two months preceding the accident he had suffered from chorea, and from the father's description it was clear that the chorea had been severe, affecting the right side of the body mostly. During the time that he was in hospital there were only occasionally very slight choreic movements, a fact which surprised the relatives greatly, and even when he was allowed up there was no return of the symptoms. The situation of the bruising showed that the left cerebral hemisphere must have received the greater part of the shock at the time of the accident, and this is the probable explanation of the inhibition of the right-sided chorea. I have since heard from his father that there was some return of the disease later but in a much milder form.

The etiological factors in these cases are numerous and varied. The following are the main conditions which influence the after-progress of patients who have sustained head injuries: (1) the natural temperament of the patient; (2) antecedent state of health; (3) the severity of the injury; (4) the efficacy of treatment adopted after the injury; and (5) other factors such as age, influence of alcohol, and social status of the patient. The natural temperament of the patient is a factor of far reaching importance. Where there is inherited or acquired nervous instability the results of head injuries are unusually severe and nervous disturbances are apt to be very persistent; indeed a neurotic inheritance may render the prospects of ultimate cure almost hopeless. I shall point out in my third lecture that traumatic insanity occurs mainly in patients with a strong predisposition to nervous disturbances; this predisposition is often a more potent factor than the actual injury. The antecedent state of health must be taken into account. With the increasing competition of modern times there is an ever-increasing number of persons who are working at high pressure with inadequate rest and such are least fitted to withstand the effects of cerebral injuries. This remark applies not only to adults; it applies also to young people in whom mental overwork is so common with our modern method of forced education. Previous acute illness, and in particular influenza, will often render the symptoms more serious. The nature and the results of previous treatment must be ascertained. Imperfect recovery after head injuries is most likely to occur in mild cases where the treatment immediately after the injury has been inefficient, and in severe cases where inefficient treatment has occurred at a later period.

I have already stated that I believe that inadequate mental rest is responsible in most cases for imperfect recovery. In again referring to this point I cannot do better than quote the remarks of Hilton: although written some 40 years ago they apply with undiminished force to the present time, for the extreme importance of this principle does not yet appear to have been thoroughly grasped. "Recognised lesions of the brain and its membranes, associated with injuries to the head, do not generally or as a principle of treatment obtain that extent of mechanical rest which is consistent with the expectation of perfect and complete structural repair. This error in the treatment of such cases is one of the chief sources of diseases of the brain. A disturbed brain recovers itself slowly; it soon becomes fatigued after use, and if claims are made upon it too soon after the injury the patient is very likely to suffer from serious consequences."

One other fact comes out strongly in my series of cases and that is, the real importance of operation in all depressed fractures of the vault. In the first series are 21 cases of depressed fractures which had been treated by operation. Of these 15 presented no ill-effects of any kind, three had slight symptoms, and three had marked symptoms; in one of the latter cases fragments of bone had been overlooked at the primary operation and were removed later. There were six cases in which depressed fractures had not been operated upon and five of these patients had not recovered from the effects of their injury. In the third series also there were several instances in which it seemed clear that injurious symptoms would not have resulted if trephining had been performed shortly after the injury; this applies mainly to cases of slightly depressed fractures in which perhaps the damage chiefly involved the inner table of the bone, the external lesion appearing trivial. These results are very striking and point to the importance of the more frequent employment of operative measures in fractures of the vault, even when there is no apparent depression.

In regard to the age of the patient, I have found that injurious effects are most likely to result at two periods, in early life and in old age. The seriousness of severe head injuries in young children seem to lie in their occurrence at a time when the higher intellectual faculties are being developed. It is usually stated that children recover remarkably well from injuries to the head, but my experience has not borne out this statement. We know that injuries to other parts of the body, when in the process of active development, are frequently followed by impairment of growth; injuries to epiphyses afford a striking example of this. It would be logical to expect that injuries to the brain in children would be even more likely to result in some permanent impairment, for its structure is more delicate and its development is more complex than that in any other region. In the aged the powers of recuperation are comparatively feeble and mental defects and impairment of memory are frequent and persistent.

It has been frequently pointed out that one of the strongest hindrances to recovery is the suspense and unsettlement of mind incidental to litigation and disputes as to compensation, and remarkable improvement may follow the termination of legal actions quite apart from the element of malingering.

In proceeding to discuss the individual *symptoms* I must point out that the investigation deals more particularly with those symptoms which, less obvious at first, interfere later with the patient's comfort and ability for work or to earn his living. epilepsy It would list of the various remote consequences which may follow injuries to the head and no attempt will be made to do so. These consequences are so numerous and varied and so frequently combined that a full description is out of the question.

I shall avoid any reference to what is known as traumatic neurasthenia, for our knowledge of the causation of the various symptoms following head injuries is as yet vague; it will, therefore, be simpler to deal with the symptoms individually. But it is, of course, of the highest importance whenever possible to determine whether symptoms are due to functional changes in the cerebral centres or whether they are the result of definite organic lesions, and further to remember that functional changes may be maintained and aggravated by organic lesions. This point has a very practical bearing on the question of treatment, for the functional disturbances can usually be cured by appropriate medical treatment, whilst the effects of organic lesions may be curable by operative measures.

Traumatic cephalalgia.—Chronic headache is by far the commonest symptom met with in patients suffering from the later effects of head injuries. It may occur alone or in combination with other symptoms and in the latter case may be the cause of, or may exaggerate, some of these other symptoms. It was present in 58 out of the 69 cases which presented any symptoms in the first series and in 43 out of the 52 in the second series. The varieties of headache in the cases are many, a fact which is readily explained by the complexity of head injuries. The pain may be continued or intermittent, localised or diffuse, fixed or radiating, in the latter case usually following the branches of the fifth nerve. Most usually it takes the form of a constant, dull, aching pain, most intense over the seat of injury. Accurate classification is obviously difficult but for practical purposes the following is useful. The pain may be general or local; in the *general* form it is referred to a large area of the head, such as the frontal, occipital, or vertical regions; the whole head seems to ache, but this aching is most intense in one particular region. The *local* forms of headache may be divided into three distinct groups: 1. The neuralgic headache, in which the pain is sharp and intermittent, radiating along the course of definite sensory nerves; this is often associated with neuralgic scars and with scars adherent to the underlying bone. 2. Headache with local tenderness. This is met with in cases in which the bone is in a condition of chronic inflammation or of osteo-sclerosis, a condition to which I shall refer later. 3. Local fixed pain without localised tenderness. In the majority of cases this is due to local intracranial lesions and more especially to meningeal adhesions. The seat of the pain, however, does not always correspond to the seat of the external injury. Pain may be on the side of the head opposite to the seat of injury, in which case the probable lesion is contrecoup bruising of the cortex with formation of adhesions. The condition may persist for years or even be permanent and is a very serious matter as it leads to insomnia, depression, and loss of appetite, and may prevent the patient following his work and attending to the ordinary duties of life. The effect of the headache upon the patient's aspect is extremely characteristic: it gives him an expression easily recognised as typical of chronic headache. Traumatic cephalalgia is frequently kept up and aggravated by alcohol and my patients almost unanimously admitted that alcohol increased any tendency to headache. The exact cause of the headache is not always certain in individual cases, for the causes are many and there is often more than one cause at work. The true neuralgic cases are not common and are almost invariably due to implication of sensory nerves in scar tissues. Such cases are usually cured by free excision of the scar down to the bone. In the neuralgic cases it is said that neuromata of the scalp or neuritis of its nerves are sometimes responsible for the pain but I know of no evidence of this.

From a surgical standpoint, by far the most important condition is that of osteo-sclerosis which occurs comparatively commonly and is peculiarly amenable to operative treatment. The pain originates in the sclerosing bone and is similar to that met with in chronic inflammation of other bones; it is fixed and usually intense, whilst there is always the characteristic local tenderness on firm pressure. The suggestion that such pain arises from the nerves of the dura mater under the thickened bone is improbable. Sir Victor Horsley was the first to insist upon the origin of this form of headache in a paper read at the Berlin Congress in 1890. He pointed out that in these cases, which are characterised by intense cephalalgia resisting all medical treatment, there are none of the sensory or motor affections met with in traumatic neurasthenia and hysteria; moreover, operation relieves not only the pain but cures the mental condition of the patient also. That sclerosing osteitis of the bone is not infrequent after fracture of the skull has been abundantly proved and this is exemplified in certain of my cases. It is probably due to the increased vascularisation after the injury and reveals itself clinically either by excessive local tenderness of the bone or as a chronic ostealgia becoming more intense under the influence of anything which increases the blood flow to the head. Occasionally atrophy of the bone follows these fractures and the symptoms may be exactly similar in character but are usually less marked. Sometimes under the atrophied osseous bone one finds enlarged Pacchionian bodies which have been accused, wrongfully no doubt, of causing the symptoms.

In other cases various lesions of the bone, meninges, or brain similar to those described in the morbid anatomy of traumatic epilepsy have been found; in some cases no lesion of any kind has been discovered and yet operation has done good. 15 months ago a patient returned to hospital two years after a bullet wound of the left parietal region, complaining of constant intense cephalalgia which prevented her performing any work. She was trephined over the seat of injury and three depressed splinters of bone, one of which had penetrated the dura mater, were removed; the headache disappeared after operation and I have recently heard that she has had no trouble of any kind since. The cerebral substance is apparently destitute of sensibility under normal conditions but it does not follow that it may not be the seat of pain after injury or in disease; indeed, small lesions in the brain not approaching the surface may cause intense pain. The dura mater receives numerous sensory and sympathetic fibres and, if the seat of acute or chronic inflammation, may unquestionably cause pain. The pia mater is said to be innervated by sympathetic fibres only, but other structures receiving only sympathetic fibres may be painful when inflamed.

The subject of *painful or tender scars* is inseparably connected with that of traumatic cephalalgia. Scars, when present, were painful in about 40 per cent. of the cases. Pain in a scar may originate either in the tissues of the scalp or in the underlying bone. In the former case the symptom usually occurs in cases where the scalp wound has been lacerated, or has not healed by first intention, or where the scar is adherent to the bone. On pulling the hair over the scar sharp pain may be complained of and is probably due to a neuralgia affecting entangled nerves; such patients may bear firm pressure on the scar without feeling any pain. The patient may tell one that tenderness of the scar is mostly noticed when he brushes his hair. In others pressure was attended by severe pain and in these cases thickening of the underlying bone is to be suspected. Pressure on the scar may produce other symptoms; thus in one case the patient was unable to lie on that part of the head on which the scar was situated owing to the intense dizziness produced by the pressure. Three patients told me that they had a sensation of "something dragging or pulling at the wound," especially when the head was placed so that the brain fell away from the region of the wound. Quick movements of the head were thus found impossible owing to the intense giddiness produced. It is possible that these symptoms are due to adhesions between the damaged part of the brain and the dura mater, so that at every movement of the head and every change of position this part of the brain is slightly dragged upon. It is obvious from mechanical considerations that the amount of cerebral movement within the cranium is very limited, but it is possible that a very small degree of traction may give rise to the sensations described.

Vertigo occurs in a large proportion of cases and may be very persistent. It was complained of in 22 out of the 100 fracture cases and, as already stated, was responsible for six patients having to give up their employment. Vertigo is independent of any aural symptom; it generally occurs with any quick movement of the head and is usually associated with headache. Often it is most noticed when the patient gets out of bed in the morning. It occurs in rising suddenly from a chair or in stooping down to tie a bootlace. It is best tested for in children by standing the upright and telling them to look up to the ceiling, especially the ceiling is high. It is obvious that these attacks giddiness may be a source of great danger. Amongst m cases are three instances in which patients were admitte into hospital with concussion, they having fallen in attac of giddiness consequent upon previous head injuries. O patient complained that giddiness in the street had sever times caused him to be mistaken for a drunken man. In few cases isolated attacks of giddiness occur without a obvious cause. In the middle of his occupation, without a preceding symptoms, the patient may suddenly be attacke with giddiness and faintness. This condition is transito and after a few hours no trace remains behind beyond t feeling of a little fatigue. I carefully considered the po sibility of this symptom being connected with lesions of t central or peripheral connexions of the vestibular nerve, b could find no evidence to support this idea. Vertigo common after injuries of all kinds and I believe it is usua a manifestation of general cerebral instability.

Attacks of *vomiting* are sometimes found and in m experience are always associated with headache an giddiness, the latter being marked. The immediate cau is probably increased irritability of the vagus centre, t wide extent of the central relations of this centre explainin its occurrence after injuries to various parts of the bra The vomiting resembles that in other cerebral affections that is to say, food is rejected soon after it is taken, the are no local gastric symptoms, nor is pain or discomf produced by the presence of food in the stomach. Nau- is often absent but occasionally may be very distressing U lateral furring of the tongue is said to occur occasionally, b I doubt if it is ever observed apart from neuralgia or disea of the fifth nerve I have frequently looked for it but ha never seen it after head injuries.

A change of disposition or character was noticed in cases in the first series and in 23 in the second seri In some the tendency was usually towards persistent depr sion and melancholia, and this was a striking feature certain of my cases. Such patients were despondent a depressed; they had lost interest in life and took pessimistic view of everything. This *depression* may the preliminary stage of a definite melancholia and th suicidal tendencies are especially strong. Three of cases had attempted to commit suicide and in two in t miscellaneous series suicide was actually committed. T evidence of depression or melancholic tendency is usua plainly marked on the man's face.

In others the change of disposition was in the directi of *irritability;* the temper became short, the patient w easily annoyed, the slightest noise, the simplest questi might arouse a furious passion. To quote an expression u by Dr. T. Clifford Allbutt, "Doors bang and windows ra as they never did before; if but a shoe-string break an i precation is on the lips; business matters are in a conspir to go wrong." The condition is at once recognised by friends or employers of the patients He is frequently fa aware of it himself and this is a sign of good progno more especially if he is anxious to overcome the sympto It shows itself in the ordinary events of every-day l there is extreme annoyance for trivial reasons. The pat gets possessed of an idea that people are conspi together against him and becomes abnormally sensitive. walking in the street he is apt to misjudge his distan and knock against people. Thinking that they were do this intentionally he flies into a temper. Drop a tray of t things in a man's room, if he has recovered from his h injury, he will use only the ordinary expressions; if recovery is incomplete he will probably fly into a vio attack of intense passion. The patients are, as it w explosive; there is loss of control. This mental irritabi is a common feature after head injuries and may last only a few months but frequently forms a permanent part o man's character.

The question naturally arises as to whether this men irritability leads ultimately to insanity. A surgeon of many years' experience, to whom I was speaking on t subject, said that "mental irritability is very comm after head injuries, whilst traumatic insanity is rare"; I certainly have found this to be the case, judging from patients whom I have investigated. The difficulty in giv an opinion on this question lies in the difficulty of keep such patients under constant observation for a large num of years and when this is possible there undoubtedly c [illegible] asylum. A typical case of this description is recorded by Mr. C. T. Dent in Tuke's "Encyclopædia of Psychological Medicine." The two conditions, depression and irritability, coexist in the majority of the patients, but one is usually more prominent than the other. In the greater number there is well-marked irritability with some depression; in most irritability is the conspicuous feature of the case.

Nervousness is another important symptom in this group. The patients are easily startled, they are frightened by slight noises, and jump violently in their chairs when doors slam. They will often tell you that they have lost their nerve. I have recently seen a police constable who was in hospital two and a half years ago with a fracture of the middle fossa followed by cerebral irritation. He is now quite unfit for work and has been placed on a temporary pension. In addition to the headache, vertigo, and irritability he has lost his nerve completely; he says he no longer has any confidence in himself; he cannot face the street traffic, and is almost afraid to cross the road by himself.

Inability for mental or physical exertion occurred for some months in practically all the severe cases of head injury which I investigated; often it lasted for a much longer period and was sometimes permanent. It was found that unusual effort was required to perform the simplest tasks, such as writing a letter. The effects of physical exertion, mental overwork, anxiety, or agitation were easily produced and unusually severe. There was fatigue on the slightest mental effort or strain of attention with a dazed, bewildered, and confused state of mind. The cerebration was sluggish and the intellectual faculties were blunted. As one of my patients expressed it: "The brain did not seem to recognise the work of the eye as before."

Some patients are apathetic. A clerk, aged 37 years, was seen suffering from nervous effects the results of concussion one and a half years previously. He described his state of mind by saying that he experienced a feeling to which he was a stranger before—namely, a dull insensibility, or, perhaps, a stolid indifference to affairs in every phase of life. He was very emphatic in stating that his symptoms were mostly felt when he was indoors and left him when he was out in the open air. This condition is essentially the result of an inadequate period of rest after the injury. The patient returns to his work before he has completely recovered and finds that any attempt at mental work results in severe headache; he is unable to concentrate his attention on any subject for more than a short time, whilst there may be neither the energy nor the ability to do physical work.

Disturbed sleep is often associated with headache, depression, and other mental symptoms. Sometimes there is short light sleep which is easily disturbed and broken by troubled dreaming. Sometimes the patients are unusually sleepy but their sleep is heavy and unrefreshing. This insomnia aggravates and is aggravated by the other nervous symptoms. Many of the patients had aged considerably since the accident and premature greyness of the hair was common. One patient, seen six years after a fracture of the base followed by severe cerebral irritation, stated that he thought the accident had added ten years to his life. In this case it was eight months before he could re-start his work as a joiner and he now cannot do very much of this.

Increased susceptibility to the influence of alcohol occurred, broadly speaking, in all the cases and forms a very striking feature. It was admitted in 60 per cent. of the fracture cases and 35 per cent. of the concussion cases. I only found but few undoubted instances in which this symptom was definitely absent. Increased susceptibility to alcohol is one of the most constant evidences of lowered resistance of the nervous system. A glass of champagne may produce headache, although formerly three or four glasses had been taken without harm. This effect is a fairly well-known one and many of my cases had not taken alcohol since the accident, in accordance with medical or other advice. The effect, moreover, is readily recognised by the patient. In other cases, where alcohol is not discontinued various secondary effects follow which must carefully be distinguished from the primary effects of the head injury. The alcoholic factor must always be taken carefully into account. Some of the patien[illegible] confirmed alcoholics and in su[illegible] was rapidly deteriorating. This [illegible] an important part on the etiology of traumatic insanity. A glass of wine or beer may produce an irritable explosion or suffice to turn these patients from apparently sane beings into irresponsible criminals.

Another feature frequently observed was *inability to stand high temperatures.* Exposure to the sun after head injuries may produce headache, giddiness, faintness, and sometimes nausea and vomiting. Direct sunlight is more injurious than mere hot weather and the oppression preceding thunderstorms is keenly felt. Occasionally a definite attack of sunstroke occurs: a boy was admitted into hospital last April with concussion; three months later he was sent to the convalescent home; one morning whilst out of doors with a cap on he suddenly had a severe attack of sunstroke, although it was quite early in the year and the sun was not particularly strong. I was recently called upon to examine a cab driver who was claiming compensation for the effects of a head injury sustained some two years ago. One complaint was that he had been unable to drive his cab during hot weather or in strong daylight owing to the giddiness and headache which resulted. This inability to bear high temperatures may become permanent and any conditions such as loss of power of concentration or failure of memory are always more marked under the influence of heat. The same result may be produced by artificial heat, as when the patient sits in front of a hot fire or works in a close confined room. In these circumstances intense head[illegible] easily produced [illegible]

I cannot give full figures upon this point. The symptom was, however, present in more than half of the patients in whom I inquired for it. Occasionally I met with cases whose symptoms were not influenced by heat but were always aggravated by cold and wet weather.

ABSTRACT OF

An Address

ON

THE PSYCHIC SIDE OF THERAPEUTICS.

Being the Annual Oration of the Hunterian Society, delivered at the London Institution on Feb. 10th, 1904,

BY J. F. WOODS, M.D. DURH.,
SUPERINTENDENT OF HOXTON HOUSE ASYLUM.

[AFTER a few prefatory remarks Dr. Woods continued as follows:—]

Year by year our knowledge of physiology and morbid anatomy increases and year by year we realise the more how great was the stimulus which the genius of Hunter gave to these sciences and how many of the practical developments of medicine and surgery had their origin in the great founder whose name and work we commemorate to-day. On this occasion I propose to dwell somewhat on the subject of Hunter's physical infirmities and to refer to certain of his views concerning the physiology of the nervous system and the manner in which body and mind act and react upon one another.

It is not a little remarkable that but few of our great geniuses have been men of robust physique, though many of them have shown great tenacity of life. John Hunter formed no exception to this rule. He was a diminutive man, some 5 feet 2 inches in height, of slender build and sensitive organisation, by its very nature prone to physical suffering, but his forceful mind ruled the small and ailing body, compelling its obedience where many a man of less dominant personality would have been ruled by it and would have drifted into confirmed invalidism. For the first 40 years of his life Hunter appears to have enjoyed fairly good health, at least there is no evidence of his having suffered any serious illness up to this time. In the spring of 1769 he had an attack of gout and in 1773 some trouble, probably of a domestic kind, affected him deeply and seems to have had mater under the thickened bone is improbable. Sir Victor Horsley was the first to insist upon the origin of this form of headache in a paper read at the Berlin Congress in 1890. He pointed out that in these cases, which are characterised by intense cephalalgia resisting all medical treatment, there are none of the sensory or motor affections met with in traumatic neurasthenia and hysteria; moreover, operation relieves not only the pain but cures the mental condition of the patient also. That sclerosing osteitis of the bone is not infrequent after fracture of the skull has been abundantly proved and this is exemplified in certain of my cases. It is probably due to the increased vascularisation after the injury and reveals itself clinically either by excessive local tenderness of the bone or as a chronic ostealgia becoming more intense under the influence of anything which increases the blood flow to the head. Occasionally atrophy of the bone follows these fractures and the symptoms may be exactly similar in character but are usually less marked. Sometimes under the atrophied osseous bone one finds enlarged Pacchionian bodies which have been accused, wrongfully no doubt, of causing the symptoms.

In other cases various lesions of the bone, meninges, or brain similar to those described in the morbid anatomy of traumatic epilepsy have been found; in some cases no lesion of any kind has been discovered and yet operation has done good. 15 months ago a patient returned to hospital two years after a bullet wound of the left parietal region, complaining of constant intense cephalalgia which prevented her performing any work. She was trephined over the seat of injury and three depressed splinters of bone, one of which had penetrated the dura mater, were removed; the headache disappeared after operation and I have recently heard that she has had no trouble of any kind since. The cerebral substance is apparently destitute of sensibility under normal conditions but it does not follow that it may not be the seat of pain after injury or in disease; indeed, small lesions in the brain not approaching the surface may cause intense pain. The dura mater receives numerous sensory and sympathetic fibres and, if the seat of acute or chronic inflammation, may unquestionably cause pain. The pia mater is said to be innervated by sympathetic fibres only, but other structures receiving only sympathetic fibres may be painful when inflamed.

The subject of *painful or tender scars* is inseparably connected with that of traumatic cephalalgia. Scars, when present, were painful in about 40 per cent. of the cases. Pain in a scar may originate either in the tissues of the scalp or in the underlying bone. In the former case the symptom usually occurs in cases where the scalp wound has been lacerated, or has not healed by first intention, or where the scar is adherent to the bone. On pulling the hair over the scar sharp pain may be complained of and is probably due to a neuralgia affecting entangled nerves; such patients may bear firm pressure on the scar without feeling any pain. The patient may tell one that tenderness of the scar is mostly noticed when he brushes his hair. In others pressure was attended by severe pain and in these cases thickening of the underlying bone is to be suspected. Pressure on the scar may produce other symptoms; thus in one case the patient was unable to lie on that part of the head on which the scar was situated owing to the intense dizziness produced by the pressure. Three patients told me that they had a sensation of "something dragging or pulling at the wound," especially when the head was placed so that the brain fell away from the region of the wound. Quick movements of the head were thus found impossible owing to the intense giddiness produced. It is possible that these symptoms are due to adhesions between the damaged part of the brain and the dura mater, so that at every movement of the head and every change of position this part of the brain is slightly dragged upon. It is obvious from mechanical considerations that the amount of cerebral movement within the cranium is very limited, but it is possible that a very small degree of traction may give rise to the sensations described.

Vertigo occurs in a large proportion of cases and may be very persistent It was complained of in 22 out of the 100 fracture cases and, as already stated, was responsible for six patients having to give up their employment. Vertigo is independent of any aural symptom; it generally occurs with any quick movement of the head and is usually associated with headache. Often it is most noticed when the patient gets out of bed in the morning. It occurs in rising suddenly from a chair or in stooping down to tie a bootlace. It is best tested for in children by standing them upright and telling them to look [illegible] the ceiling is high. It is obv[illegible] giddiness may be a source of great danger. Amongst my cases are three instances in which patients were admitted into hospital with concussion, they having fallen in attacks of giddiness consequent upon previous head injuries. One patient complained that giddiness in the street had several times caused him to be mistaken for a drunken man. In a few cases isolated attacks of giddiness occur without any obvious cause. In the middle of his occupation, without any preceding symptoms, the patient may suddenly be attacked with giddiness and faintness. This condition is transitory and after a few hours no trace remains behind beyond the feeling of a little fatigue. I carefully considered the possibility of this symptom being connected with lesions of the central or peripheral connexions of the vestibular nerve, but could find no evidence to support this idea. Vertigo is common after injuries of all kinds and I believe it is usually a manifestation of general cerebral instability.

Attacks of *vomiting* are sometimes found and in my experience are always associated with headache and giddiness, the latter being marked. The immediate cause is probably increased irritability of the vagus centre, the wide extent of the central relations of this centre explaining its occurrence after injuries to various parts of the brain. The vomiting resembles that in other cerebral affections—that is to say, food is rejected soon after it is taken, there are no local gastric symptoms, nor is pain or discomfort produced by the presence of food in the stomach. Nausea is often absent but occasionally may be very distressing. Unilateral furring of the tongue is said to occur occasionally, but I doubt if it is ever observed apart from neuralgia or disease of the fifth nerve I have frequently looked for it but have never seen it after head injuries.

A change of disposition or character was noticed in 35 cases in the first series and in 23 in the second series In some the tendency was usually towards persistent depression and melancholia, and this was a striking feature of certain of my cases. Such patients were despondent and depressed; they had lost interest in life and took a pessimistic view of everything. This *depression* may be the preliminary stage of a definite melancholia and then suicidal tendencies are especially strong. Three of my cases had attempted to commit suicide and in two in the miscellaneous series suicide was actually committed. The evidence of depression or melancholic *tendency* is usually plainly marked on the man's face.

In others the change of disposition was in the direction of *irritability;* the temper became short, the patient was easily annoyed, the slightest noise, the simplest question might arouse a furious passion. To quote an expression used by Dr. T. Clifford Allbutt, "Doors bang and windows rattle as they never did before; if but a shoe-string break an imprecation is on the lips; business matters are in a conspiracy to go wrong." The condition is at once recognised by the friends or employers of the patients He is frequently fully aware of it himself and this is a sign of good progress, more especially if he is anxious to overcome the symptoms. It shows itself in the ordinary events of every-day life; there is extreme annoyance for trivial reasons. The patient gets possessed of an idea that people are conspiring together against him and becomes abnormally sensitive. In walking in the street he is apt to misjudge his distances and knock against people. Thinking that they were doing this intentionally he flies into a temper. *Drop a tray of tea things in a man's room, if he has recovered from his head injury, he will use only the ordinary expressions; if his recovery is incomplete he will probably fly into a violent attack of intense passion.* The patients are, as it were, explosive; there is loss of control. This mental irritability is a common feature after head injuries and may last only for a few months but frequently forms a permanent part of a man's character.

The question naturally arises as to whether this mental irritability leads ultimately to insanity. A surgeon of very many years' experience, to whom I was speaking on this subject, said that "mental irritability is very common after head injuries, whilst traumatic insanity is rare"; and I certainly have found this to be the case, judging from the patients whom I have investigated. The difficulty in giving an opinion on this question lies in the difficulty of keeping such patients under constant observation for a large number of years and when this is possible there undoubtedly occur of securing his full confidence, which, having done, I get him to relax his muscles to the utmost, and I insist on complete silence, the only sound heard being that of the rhythmic movement of my hand as I stroke the upper part of the face or, as sometimes happens, the arms. This silence I have found in many cases more impressive than words and a suggestion made at the end of a pause of this sort is, in my experience, far more effective than the uninterrupted drone of a voice making the same suggestion in different phrases, as is the custom of Bernheim who, like myself, resorts to treatment by suggestion without hypnosis. All this time I remain myself as reposeful as possible. I seek in fact to create an atmosphere of repose and silence which is in itself impressive and tends to induce a feeling of well-being and expectancy in the patient. If, when the psychological moment has arrived, I make a suggestion I get an effect such as I cannot so readily obtain in any other way, save by inducing actual hypnosis, which many patients object to and for which there is in the majority of cases no necessity whatever. In most cases there is no need whatever to send the patient to sleep. Suggestions can in almost all cases be made quite as effectually without hypnosis as with it and certainly in the case of many patients whom it would be impossible to hypnotise. A further advantage of this plan is that treatment can often be carried out in séances of quite short duration and in the consulting room, though in difficult cases it may be advisable to visit the patient at his own house in the evening at the hour of natural sleep and in still more obstinate cases it may be necessary to remove the patient from injurious home influences.

With regard to the suggestion, which is the essential curative agent, there must be no kind of uncertainty about the manner of making it; it must be forcible, deliberate, unmistakeable. John Hunter says: "A fixed principle fixes the mind but a doubtful one leaves it no rest." He goes on to say: "Anxiety is expressive of the union of two passions—desire and fear." In the patient's mind the desire is to get well; the fear is that many kinds of treatment having already failed this one will fail also. The suggestion must therefore be made in such a way as to give the patient confidence both in the physician himself and in his methods. The patient's desire to be restored to health must be accentuated and any doubt that this will not be accomplished dispelled. But before the physician can speak with this necessary authority he must have gauged the exact condition of his patient and himself be inspired with confidence in his powers so that he may infect his patient with it. It is this very confidence, or arrogant pretence of it, which enables the blatant charlatan often to succeed where the legitimate but more modest and hesitating practitioner may fail, for though the latter may begin by feeling pretty sure of success doubts are almost certain to crowd up in his mind—the strange vagaries of disease, the unexpected turns it may take, the infinite variety of constitution and temperament that are encountered, the manifold outside influences that may operate injuriously but especially in the case of the neurotic—all these considerations rise up to disconcert him and to rob him of that very confidence which is so necessary to success in inducing hypnosis or in making an effective suggestion. I find, surprising as it may seem, that more confidence and experience are required to implant an effective suggestion independently of hypnosis than are required to induce the hypnosis itself and I am therefore in the habit of advising beginners always to seek to produce complete hypnosis before offering the therapeutic suggestion, later to practise Bernheim's method of constantly repeating the suggestion without first inducing hypnosis, gradually feeling their way towards the more simple method which I have described.

[Dr. Woods here referred to the facilities which asylum pr[illegible] the art of psycho-therapeusis ar[illegible] ysician should make all the use he can of suggestion, so contrariwise the physician who devotes himself especially to this line of treatment should be prepared to make full use of other therapeutic methods besides suggestion, should they be called for. Thus if a patient suffers from chlorosis I of course give iron; if there is neuralgia from gummatous formation I prescribe large doses of iodide; if there is chronic gastro-enteritis I recommend a careful dietary; or if the patient is profoundly emaciated I may find it necessary to resort to the Weir-Mitchell treatment. But in all these methods of treatment I find I get great help from suggestion. In a case undergoing Weir-Mitchell treatment much can be done by suggestion to calm a restive patient, to improve sleep and digestion, and to remove such disagreeable symptoms as neuralgia and headache. In these cases I sometimes find it necessary to see the patient daily, but for the majority two or three visits a week suffice; later, a single weekly visit may be sufficient. Here let me emphasise the importance of securing the services of the right kind of nurse in carrying out the rest cure. She must be tactful, resourceful, gentle, firm, quiet, and patient, a combination of qualities possessed, I need scarcely say, by but few.

The disorders in which the best results are obtained by suggestion are, of course, those depending upon functional disturbances of the nervous system, such as tremor, chorea, neuralgia, headache, sleeplessness, palpitation, epilepsy, mental diseases, chronic alcoholism, and the various drug habits. But, as I have already said, suggestion may prove of service in the treatment of most maladies and I have by its means been able to alleviate serious organic diseases, such as valvular disease of the heart Graves's disease, and locomotor ataxy. It is, of course, needful to tell the patient in all such cases that absolute cure cannot be effected.

[Dr. Woods here showed elaborate tables containing statistical results. The names of the several diseases treated and the number of patients suffering from each of them were as follows.—Neurasthenia, 245; writer's cramp, 10; chronic alcoholism, 115; stammering, 6; headache, 158; melancholia, 79; dyspepsia, 62; arthritis, 43; neuritis, 20; insomnia, 44; neuralgia, 95; lumbago, 6; torticollis (spasmodica), 13; sea sickness, 3; sickness of pregnancy, &c., 4; impotence, 8; sciatica, 39; asthma, 4; masturbation, 9; nocturnal incontinence, 5; gout, 10; urticaria, 3; blushing, 2; pain, 5; night terrors, 2; stage fright, 10; biting nails, 1; epilepsy, 26; functional paralysis, 9; hysteria, 7; menorrhagia, 4; morphia habit, 7; tinnitus, 4; sprain, 1; spinal neuralgia, 5; chorea, 35; obsession, 2; locomotor ataxy, 3; spasm, 2; delusions, 2; bad temper, 2; pianist's cramp, 1; rheumatism, 2; tremors, 3; delirium tremens, 1; deafness, 8; and palpitation and heart troubles, 11. The grand total of patients treated was 1129, of whom 868 were tabulated as "apparently recovered," 125 as "improved," and 136 as "no apparent change." Dr. Woods also gave detailed clinical descriptions of 14 cases, from among which the six following are selected as illustrative. Lantern pictures were shown exhibiting the handwriting (before and after treatment) of several patients suffering from writer's cramp and chorea. In all cases the writing was better after the treatment.]

CASE 1.—The patient was an unmarried female, 24 years of age. She had suffered from facial neuralgia for four years. No medicine relieved her for more than a few days. [illegible] not sleep and was weak and depressed. She was [illegible] th, 1892, and sugges- [illegible] 15 minutes, to awake with no pain, to be bright and cheerful, and to sleep well at night. Everything happened as suggested. The patient awoke laughing without any pains and slept well at night, the neuralgia not returning until 12 days afterwards, when she was again hypnotised, since when (with the exception of a few hours' pain due to a carious tooth during November, 1895) there has been no recurrence of pain.

CASE 2.—The patient was a married woman, 36 years of age. She consulted me in the summer of 1897 for sciatica in the right leg. She had been laid up on and off for about eight months and the pain was at times very acute. Such was the case when I saw her; she limped and was obliged to support herself [illegible] during the [illegible] blisters, ba[illegible] by suggestion only, placing my hand very gently on the back of her hip, outside her dress, when she immediately expressed herself as free from pain. It disappeared instantly. This was the quickest result I have had and surprised no one more than myself. I told her to lie on the couch for half an hour afterwards and then to get up. There was no return of the pain at the end of this time. On leaving me she laughed and said, "I daresay you think I am a fraud, but I asssure you I suffered tortures." She came again three days afterwards, expressed herself as feeling well, and had had no appreciable pain, but the leg was a little weak. In 1902 I saw her again for other troubles but she had kept entirely free from sciatica.

CASE 3.—The patient was a man, 34 years of had [illegible] the [illegible] leg for 18 [illegible] and had been treated at home and abroad during the whole period of his illness. He came to me in 1895 saying that he could not sleep or walk 100 yards without acute pain. I treated him by suggestion and pressed my fingers outside his clothes on the painful spots and gently stroked his leg from above downwards. In about ten minutes all pain vanished and he performed various gymnastic feats in order to see if the pain would return but it did not. At the same time he told me that he did not believe in me or my treatment but he meant to give everyone a trial until he got relief. He walked up and down my room for about an hour, doing all sorts of movements, and then went for a brisk two-mile walk, and in two days I had a letter from him saying that he felt a little tired after walking but the pain had not returned. He visited me two or three times after this to show how well he had remained since the treatment.

Case 4.—The patient was an unmarried female, 37 years of age. She was sent to me by Dr. D. Ferrier from the National Hospital for the Paralysed and Epileptic, suffering from functional paralysis of the left leg. She had been under treatment for two years, her leg was wasted and cold, and she walked on crutches, dragging the foot and unable to put her weight on it. I treated her by suggestion only three times in one week and she was able to walk after the third treatment. For the first treatment I suggested that her leg should feel warm and comfortable. It actually became warm in a quarter of an hour. For the second treatment I suggested that she should be able to move it, which she did slightly in ten minutes. For the third treatment I suggested that she should be able to stand on it and walk, which she did in half an hour, but only with great difficulty on account of the weakness. After this she steadily improved; in about a month the leg was of the same size as the other and she walked then as if she had never been ill.

Case 5.—The patient was a married woman, 60 years of age. She consulted me on Nov. 9th, 1901, complaining of constant pain in her right leg, extending from the knee to the ankle on the outer side. The pain had lasted for six months and nothing gave her relief. No cause for the pain could be ascertained. She had recently undergone a rest cure (Weir-Mitchell) and had had treatment for gouty dyspepsia and neurasthenia and expressed herself as feeling well except for the pain in her leg. I treated her by suggestion only, saying that the pain would go, placing my hands where the leg was painful. In about ten minutes she told me that every vestige of pain had disappeared and she walked with comfort about the room. I saw her last summer and she told me that she had had no pain in her leg since I treated her. One treatment was sufficient.

Case 6.—This case is well known to you. The patient was at King's College Hospital under the care of Dr. Ferrier and was sent to me by Sir Hugh Beevor at the end of January, 1895. I show examples of her writing; she had a peculiar tremor of the right hand. She was treated by short hypnotic sleeps and I believe has kept well.

Objections.

Some members of our profession have still a rooted aversion to treatment by hypnosis and from their writings one would almost suppose that they would rather not cure at all than resort to it. For this they assign various reasons, the most important being that the operator can if he so chooses acquire an undue and injurious influence over his patient. This grave indictment has been so effectually disposed of by Dr. J. Milne Bramwell in his excellent work[2] that it is unnecessary for me to say anything further on it. Even granting, however, that the medical man could obtain through hypnotic means an unhealthy influence over his patients the fact could not legitimately be used as an argument against the therapeutic use of hypnosis. Should he so wish to influence his patients there is surely no ne to resort to hypnotism for the purpose; but why should desire it any more than he should desire to injure them the employment of other well-tried therapeutic mean Assuming that he can make a poisonous use of hypnosi can he not also make a similar use of drugs? and no ma worthy the name of physician is likely to do the one an more than the other.

But while this absurd charge carries its refutation upo the very face of it the case is far otherwise in regard to th employment of hypnotic treatment by the unskilled layman The danger here is not so much that the operator shal acquire an undesirable influence as that he shall, through random and indiscriminate use of a subtle and potent agent, inflict serious injury. The public is constantly suffering a the hands of the so-called healer. This over-credulous and gullible public is willing—nay, anxious—to regard the power to hypnotise as some mysterious spiritual gift rather than as an attribute possessed by all and explicable on known natural laws. They cannot look upon hypnotic treatment as they do upon treatment by drugs or electricity, or Roentgen rays, or other recognised therapeutic agent to be prescribed by a physician only.

The so-called faith-healer knows nothing of the nature of the disease which he presumes to treat or of the difficulties which lie in his path. Blind men have by faith been made to see, deaf men to hear, lame men to walk, then why should not (so he argues) a cure of the case before him be similarly effected? The fact that there may be an insurmountable barrier in the way of cure, that the case may be essentially one for surgery or for antisyphilitic treatment, enters not into his mind. If it should chance to be one which lends itself readily to his methods he will succeed for a time at any rate; and if not he recks nothing of the precious time and opportunity he may be wasting while the patient is being deluded with the false hope of recovery.

There are, however, signs that the opposition which treatment by suggestion has met with is growing daily less and less and that this potent therapeutic method bids fair soon to be taught in our schools as a matter of routine. For myself I am gratified and proud to say that I have received much help and encouragement from my professional brethren in pursuing this line of treatment and my relations with them have ever been most cordial and pleasant.

ABSTRACT OF

An Inaugural Address

ON

THE DIMINISHING BIRTH-RATE AND WHAT IS INVOLVED BY IT.

Delivered before the British Gynæcological Society o Feb 11th, 1904,

By JOHN W. TAYLOR, M.Sc. Birm.,
M.D. Brux., F.R.C.S. Eng.,
PROFESSOR OF GYNÆCOLOGY IN THE UNIVERSITY OF BIRMINGHAM;
PRESIDENT OF THE BRITISH GYNÆCOLOGICAL SOCIETY.

The address was divided into four parts. The first was devoted to a critical study of the statistics of the subject during the last 25 years. The birth rate of the United Kingdom was compared with that of other countries, both east and west, and it was shown that during the last 20 years no other nation has sustained so great a loss as we have in this definite period of time. The marriage-rate in the United Kingdom during the same period was found to be slowly rising so that the "birth loss" was necessarily due to causes operating in the married life of our population and not simply due to celibacy. The value of the population of to-day was then compared with that of 20 years ago and it was found that in juvenile criminality, in mental disease and brain weakness, and in alcoholism the restricted population of the present day compared unfavourably with the freer population of a former generation. A tentative *effort* was then *made over* a limited field to compare the general culture of the more intellectual classes of the two generations and this (so far as it went) was found to work out disadvantageously to the present generation. The work of Professor Karl Pearson on heredity was then considered and was found to point to a similar conclusion. "All of this tended to show that the marriages of to-day *were not only relatively sterile but either* (1) *that the* children born of such marriages were weak, neurotic, specially liable to alcoholism, criminality, and insanity, and so far unfit for the battle of life; or (2) that marriages of the middle and better classes were now so sterile that quite an [illegible] generation was [illegible], the more vicious [illegible]

---

[2] Hypnotism: Its History, Practice, and Theory, 1903.

The second part of the address dealt with the cause and life-history of these "relatively sterile" marriages. The cause was traced to the deliberate prevention of conception and reasons were brought forward supporting the view that this was not only destructive of the future life of the nation but seriously injurious to those who practised it and to such children as were "arranged" for and produced. The prevalent neurasthenia of the present age was increased by the practice and the absence of sexual restraint encouraged by it had an evil effect on the moral character which was liable to be transmitted to the children. In addition to this, the child of the relatively sterile marriage suffered from a debased and stunted education. "Reared in greater comfort or comparative luxury, with no brothers or sisters of similar age to rub off its angles and selfishness, it was ill-prepared for every step of the succeeding battle of life and it was very frequently the child of the larger family and poorer parents who pushed his way [illegible]"

The p[illegible] the third part of [illegible] present condition and statistics of France where, for 60 years, the birth-rate had been falling until the population had become stationary or even less than stationary. "During the last 50 years criminality had trebled in France, that of children and young people being specially remarkable, and particularly so regarding crimes of lust and prostitution. During the last 20 years the consumption of alcoholic drinks had trebled and France had passed from the seventh place in order of consumption of alcohol to the first. Insanity was steadily increasing and the ratio of suicides had risen from 112 per million in 1880 to 205 (or nearly double) in 1885" It was pointed out that after half a century of trial with an increasingly limited population France showed more and more a lowered and still falling moral average, a lessening virtue or strength, and an increasing national neurasthenia which seemed to crave and to need the help of constant stimulation in order to face the ordinary routine of life. The future danger of this under a democratic form of government was considered and insisted on. So long as the race progressed the people could be trusted with the powers of government, but when decadence had been going on for years, and even ages, what could be the final outcome of such democracy but anarchy and confusion?

The fourth part of the address dealt with the treatment of this national evil, apportioning to the Church, the State, and the profession of medicine their proper share in the re-creation of a healthier moral standard and practice. "The birth loss in the United *Kingdom must be due to* causes operating in the married life of its inhabitants." Therefore there was no reason to fear any high ideal of chastity or continence and especially when this was associated with the care of those forces which go for the defence of the nation and that child life which was its future hope. On the other hand, there was every reason to fear that debased ideal of married life which was secretly and insidiously working for the ruin of the nation's power and for the destruction of its hope. National decay or degeneration was by no means the inevitable consequence of age, as some had supposed. The history of Japan was one evidence of this and it was worthy of notice that the pre- [illegible]

Insisting on the necessity of arousing the public conscience and of aiming at a truer and braver conception of life, Mr. Taylor concluded by saying that he must confess when he heard of thoughtful men among the Boers in South Africa, military authorities in St. Petersburg, and Japanese in *far Japan noticing and counting on their own racial increase* and comparing this (kindly or unkindly) with our own comparative stagnation, he would like if he could to sting his fellow countrymen into some proportionate sense of shame and duty. He thought that in his responsible position as the temporary head of a great British society, which was an authority on such questions he was surely not overstepping *his province if he asked*, not so much *for* any *following* of his leadership, as for the fullest independent investigation into all the facts, figures, and arguments which he had brought forward.

THE USE OF ANTISTREPTOCOCCIC SERUM IN THE TREATMENT OF SCARLET FEVER AND OF DIPHTHERIA.

By F. PERCIVAL MACKIE, F.R.C.S. Eng.,
LIEUTENANT, I.M.S.; LATE RESIDENT MEDICAL OFFICER AT THE BRISTOL CITY ISOLATION HOSPITAL.

DURING the 18 months in which I had charge of the Bristol City Isolation Hospital (June, 1900, to January, 1902) nearly 950 cases of scarlet fever passed through my hands and the mortality of all these worked out at just over 2·25 per cent. These figures when compared with those, say, of the Metropolitan Asylums Board, where the mortality is rarely under 4 per cent, look satisfactory. It would, however, I think be erroneous to draw any deductions from this comparison as the total number of Bristol cases is small, and moreover epidemics of scarlet fever vary so much in their severity that very large numbers of cases must be examined before one can draw accurate deductions. My object in this paper is not, however, to institute comparisons between sets of statistics but to examine individual cases as carefully as possible and to note what effect the use of antistreptococcic serum produces on severe cases of scarlet fever. I have notes on 22 cases so treated and five cases of diphtheria which have been treated both with antistreptococcic serum and diphtheria antitoxin. This latter series of five cases I shall refer to separately as they present unusual features and are of particular interest.

With the exception of a few cases which were admitted in such a condition as to render any treatment useless, all the severest cases were treated with serum; so, though the cases were selected, it was only the very worst of the patients (with the above exceptions) who were submitted to it. The serum at first used was that obtained from the Lister Institute of Preventive Medicine; latterly that prepared by Messrs. Burroughs, Wellcome, and Co. was also used, and I then gave the different strains alternately. If I were treating a number of patients with anticoccic sera again I should procure samples from as many sources as possible and give them alternately, on the principle that one would be more likely to hit off the particular variety of coccus causing the disease under treatment

In reading records of cases of various diseases—e.g., puerperal fever, ulcerative endocarditis, pyæmia, erysipelas, &c., which have been treated with antistreptococcic serum—one cannot help *being* struck with the inconsistence in the results. One man writes enthusiastically to record a brilliant result and another in apparently similar cases reports repeated failure. This inconsistence is fully borne out by my own experience and in watching other cases in hospital, and one can never say beforehand, even with a full bacteriological report before one, which case is likely to be benefited by serum treatment and which will not. The treatment, though rational in theory, is empirical in its results. The reason of this is that bacteriology has not yet decided the relationship between the numerous forms of cocci met with in quite dissimilar diseases. Are they all the same organism under different degrees of attenuation or virulence, modified by the reaction of the tissues in which they find themselves and by the function or anatomical position of the organ in which they

y.u h.

are flourishing? Or, on the other hand, have such dissimilar diseases as osteo-myelitis and meningitis, general peritonitis and stitch abscess, ulcerative endocarditis and boils, each their own peculiar micrococcus? If the first condition holds then the serum from any of these cocci should produce at least some effect on all these different diseases, whilst if the latter supposition is correct then one would expect a disease to react only to the serum prepared from that particular strain of organism. Until, therefore, the identity or otherwise of the numerous cocci known to bacteriologists is settled, treatment with antistreptococcic serum must remain in the regions of empirical therapeutics.

I have inquired into the possibility of manufacturing a polycoccic serum—i.e., one made from a number of cocci from various sources—and I understand that some laboratories have considered (or have actually carried out) the preparation of such a serum.

I now proceed to deal with the various phenomena more in detail.

Type of disease.—In 16 out of the 22 cases the type was that known as anginal or anginose with evidence in every case of a greater or lesser degree of sapræmia. In four cases there were signs of either septicæmia or pyæmia and in the latter cases abscesses were found either ante or post mortem either in joints or one or other of the viscera. The local condition of the throat in these anginose cases was as follows. The milder cases showed much exudation of muco-pus and the pharyngeal walls were stiff and brawny and excessively painful; well-marked cervical buboes were present. The severest cases (and these formed by far the larger number) presented actual ulceration and sloughing of the soft palate and tonsils, the throat was choked with pus, often stinking, and hæmorrhage was not infrequent. Ulcerative stomatitis was often seen involving large areas of the inner aspect of the cheeks and purulent rhinitis which excoriated the nostrils and double otitis media were very frequent complications. Large cervical buboes which went on to suppuration also occurred. The two great dangers from this condition were first that arising from the continuous absorption of septic material and sapræmia and secondly that of insufficient feeding. The first was combated with two-hourly lavage of the throat with chlorine solution and the latter was met only by increasing vigilance and unremitting attention and patience on the part of the nursing staff (particularly on the part of the sister in charge of the infant ward).

Bacteriology.—In six cases where the blood was examined during life it was found sterile in three cases; in two pure staphylococcus pyogenes albus was found and in one mixed staphylococci and streptococci. In four cases where the blood was examined after death one was sterile, one contained pure streptococci, and two showed mixed cocci. In seven cases where cultures were made from the throat six grew mixed cocci and one showed chiefly streptococci. In several cases cultures were made from the pus of secondary abscesses or from internal organs where generalised infection was suspected. In every case that died a complete post-mortem examination was made. In two cases my finger was pricked when sewing up the corpse and in both instances severe lymphangitis and small local abscess resulted. From the first abscess pure staphylococcus pyogenes albus was cultivated and in the second abscess a short streptococcus was found, in each case the same organism previously cultivated from the patient's blood during life. Two cases had tracheotomy performed for œdema of the glottis; both died.

Serum injections.—One bottle (approximately ten cubic centimetres) was the invariable dose. Six patients had one dose only, five patients had two doses only, six patients had three doses only, two patients had four doses only, one had five doses, one had six and one had seven doses. One patient had, in addition, 1000 units of antidiphtheritic serum and another had 5000 units of the same on the suspicion of their having diphtheria which was not subsequently confirmed by bacteriological examination. The serum was introduced by means of an antitoxin syringe with asbestos plug, the whole instrument being taken to pieces after each injection and boiled. The injection was made into the flank or abdomen under antiseptic precautions. Beyond causing slight irritation at the time the injection caused no discomfort in most cases. There was a blush seen round the site of injection in three cases next day with slight tenderness which both disappeared in a few hours. One child developed a local chronic abscess at the site of injection; at the end of a week it was opened up and a teaspoonful of ropy pus like starch emulsion was evacuated. Cultures made from this pus grew a weakly coccus only after four days' incubation; this coccus quickly died out. This patient subsequently developed a large abscess around the shoulder-joint and later one in the abdominal wall and only recovered after a tedious illness. I have dwelt on this case because it is the only one where I suspected the serum of having done harm. Even in this case it is impossible to say whether the condition of pyæmia which arose subsequently and the staphylococcus pyogenes albus found in the blood stream were due to the inoculation of septic serum or whether these complications arose in the natural course of the disease.

Effect of the serum on the temperature, &c.—In the majority of cases no marked effect on the temperature was noted, though the general tendency was for the thermometer to rise from 0·5° to 1° F. Sometimes the injections were followed by a marked rise of 3° or 4° and I think in these cases the serum seemed to be beneficial.

Rashes.—The occurrence of well-marked maculo-urticarial rashes was not uncommon. The first evidence was the presence of salmon-coloured angular maculæ on the face and neck; these deepened in colour and became markedly urticarial and irritating. The colour disappeared on pressure, leaving a yellow stain, and the rash lasted about two or three days, gradually fading. Other rashes were noted which probably depended on the absorption of septic material. Some were of the nature of dark hæmorrhages over the body and especially over points of pressure—e.g., heels and buttocks, and others were present as multiform punctate hæmorrhages and purpuric blotches.

Albuminuria was common but actual nephritis was rare; only about three cases of frank nephritis occurred in 900 cases, though in several instances the kidneys were found post mortem to present evidence of early disease. It may seem anomalous to state that hæmaturia was commoner than albuminuria, but over and over again I was attracted to a very smoky urine expecting to find a large quantity of albumin and only to find a barely detectable trace.

Five Cases of Diphtheria treated with Diphtheria Antitoxin and Antistreptococcic Serum.

CASE 1.—The patient was a child, eight years old, who had been taken ill with malignant diphtheria six days before admission to hospital and was in a hopeless state when admitted, the throat being filled with putrid sloughs and blood and emitting an indescribable stench. The neck was swollen up to the level of the chin. Klebs-Löffler bacilli and mixed cocci were present. The child's temperature was 97° F. Ten cubic centimetres of antistreptococcic serum and 4000 units of diphtheria antitoxin were given in one dose. The child died on the day after admission. The necropsy showed partial destruction of the soft palate and tonsils, as well as the presence of suppurative adenitis, hæmorrhages into the tissues, necrotic areas in the small intestine, and septic bronchitis.

CASE 2.—The patient was a child, 12 years old, who showed a good deal of membrane in the throat and had a temperature of 103·6° F. The general symptoms were very severe. On admission to hospital the patient was covered with an extraordinary rash of the following characters. It was composed primarily of circles of erythema, each circle varying in size from that of a sixpence to that of a shilling and being of a dull scarlet colour. Some of these circles were discrete but others had coalesced into a large patch or patches of about the size of a saucer with crenate edges due to the circular shape of the composing elements. In most of the circles there was an eccentric ulcer or scab and sometimes there was a small pustule. The hands looked as if their palms and backs had been dipped in red ink. These scarlet areas were not painful; they disappeared on firm pressure, returning instantaneously. On the left side of the neck from the clavicle to the ear there was a dusky red area not painful or swollen but disappearing on pressure. The left ear was deeply congested and purple. The throat yielded diphtheria bacilli on culture and staphylococci and streptococci as well. The blood withdrawn from the cephalic vein grew a few isolated colonies of streptococci and white staphylococci. The leucocytosis was 13,700 per cubic millimetre. Widal's reaction was negative. There were marked nervous phenomena, semi-coma or busy delirium, subsultus tendinum, and marked tremor of the hands. On the day of admission 3000 units of diphtheria antitoxin, obtained from Messrs. Burroughs, Wellcome, and Co., were given. On the second day 3000 units of diphtheria antitoxin plus 10 cubic centimetres of antistreptococcic serum were given. On the third day only 10 cubic centimetres of antistreptococcic serum were given. On the fourth day 1500 units of diphtheria antitoxin plus 10 cubic centimetres of antistreptococcic serum were given. On the fifth day the temperature was between 101° and 102°; on the sixth day it fell to normal and did not rise again.

This was one of the severest cases treated with serum and no hope was given of the patient's recovery. He apparently had pyæmia as well as diphtheria. Death seemed inevitable on the fourth day and on the sixth he was practically convalescent. Diphtheria bacilli were found in his throat at intervals for several weeks. The curious rash mentioned lasted till the sixth day and then faded. He subsequently developed paralysis of the soft palate (complete), of the irides (complete), of the diaphragm and lower intercostals (apparently complete), and of both arms (partial). He also had marked cardiac irregularity. He was ultimately discharged well having recovered from all his paralyses (strychnine was freely given). In reference to the peculiar rash I have seen a similar condition in the case of a man who suffered from pyæmia and was under the care of Dr. A. J. Harrison of the Bristol General Hospital whilst I was his house physician. This man was subsequently treated with antistreptococcic serum but died. I believe these small ulcers or pustules are due to pyæmic emboli in the skin which later become surrounded with vivid erythema. This explanation was suggested to me by the case of a man dying from ulcerative endocarditis who in his last hours had a shower of emboli discharged into his blood stream most of which lodged in the skin of the abdominal wall. This was the early stage of the circular erythematous condition above noted.

CASE 3.—The patient was three years old and was too far gone for benefit to be expected from any treatment. The child was admitted with severe anginose scarlet fever and diphtheria was only discovered the day before death. Vomiting set in early, rectal feeding failed after one day's trial, and for two days before death no nourishment was retained. Two doses of antistreptococcic serum were given on the third and fourth days respectively, and 8000 units of diphtheria antitoxin on the day before death. Klebs-Löffler bacilli were found in the throat culture with mixed cocci. The heart's blood after death yielded a small variety of pure staphylococcus albus and cultures from the spleen showed fine colonies of a long streptococcus.

CASE 4.—The patient was eight years old and suffered from malignant diphtheria with huge brawny swelling of the neck and suppurative cervical adenitis. The throat was filled with putrid black sloughs and oozing blood giving off a horrible fœtor. There were hæmorrhages at various points over the body. On the first day the temperature was 101° F.; 6000 units of diphtheria antitoxin, obtained from Messrs. Burroughs, Wellcome, and Co., were given. On the second day the temperature was 99·6°; 2000 units of diphtheria antitoxin and ten cubic centimetres of antistreptococcic serum were given. On the third day the temperature was 98·6°; ten cubic centimetres of antistreptococcic serum were given. The swelling in the neck subsided rapidly but the general symptoms of toxæmia prevailed and death took place on the sixth day very rapidly from cardiac failure.

CASE 5.—The patient was four years of age and the symptoms were chiefly laryngeal from the first, so that tracheotomy was performed on the morning after admission. On the first day 4000 units of diphtheria antitoxin were given. On the second day tracheotomy was performed and long strips of membrane were taken out of the trachea. On the third day 4000 units of diphtheria antitoxin were given. There was frequent vomiting and early nephritis was noted. The throat was almost stopped by œdema and thick pus. On the fourth day 4000 units of diphtheria antitoxin and ten cubic centimetres of antistreptococcic serum were given. Nothing was retained by the mouth and only a little by the rectum. On the fifth day all the symptoms were alleviated and the tracheotomy wound was healthy; ten cubic centimetres of antistreptococcic serum were given. The child died suddenly on the same evening whilst being fed, presumably from heart failure. The necropsy showed an antemortem clot in the right auricular appendix.

CONCLUSIONS.

It is only recently that the paper has been compiled from clinical, bacteriological, and post-mortem notes and temperature charts which had been kept for three years, and these conclusions are arrived at only after the careful re-examination of the cases at a distance of time when any excess of bias may reasonably be expected to have evaporated.

1. Antistreptococcic serum is of distinct value in a certain number of cases of scarlet fever, particularly in those where the throat lesion is severe and toxæmia is going on.
2. Bacteriological examination will give no sure guide as to the cases in which serum will be beneficial, therefore it is advisable to give the serum early and to make the bacteriological examination afterwards.
3. The serum ought to be given early in the disease just as in diphtheria. The longer the disease has lasted before the serum is used the less likelihood is there that it will be beneficial. Antistreptococcic serum is too often brought in with the strychnine and oxygen when it is unreasonable to expect it to do good.
4. If the first dose or two have no effect on the temperature its continuation will probably not be of any value.
5. The serum is liable to produce urticario-erythematous rashes.
6. Even in those cases in which it does no good there is no evidence to show that it does harm.

Diphtheria treated with Combined Sera.

At the Public Health Laboratories in Bristol, where for a period of several years I had the opportunity of examining many hundred cultures of diphtheria, it was our experience that the severest cases clinically were those whose cultures showed an admixture of streptococci and Klebs-Löffler bacilli. Conversely when the cultures showed almost pure Klebs-Löffler bacilli the clinical characters were generally returned as "mild." It would be too much to say that the severity of the clinical symptoms was in inverse proportion to the number of Klebs-Löffler bacilli present in the culture, but that statement would be as true as many medical aphorisms are. Particularly severe cases are said to be associated with the presence of so-called "battalion cocci"—i.e., streptococci arranging themselves in squares or squads—and this statement is also borne out by my experience. An epidemic of diphtheria in North Somerset in which I was responsible for the bacteriology only confirmed my views on the above points. These things being so, the *raison d'être* for the treatment of diphtheria by antistreptococcic serum is established, its value remains to be proved.

On looking through the five cases recorded one can by no means say that the treatment was successful, but as at least three patients out of five were almost moribund on admission, as one died from heart failure when convalescent, and as one recovered almost miraculously the result was not so bad as the figures tend to show. I am strongly of opinion that in all cases of diphtheria where there is good evidence of septic infection—i.e., where there are sloughing in the throat and any degree of swelling of the neck and a high temperature—antistreptococcic serum should be given, with some confidence that in a certain number of the cases the septic element will be alleviated. In most cases of diphtheria where death occurs during the first week or ten days of the disease the patients die from the septic element, not from the diphtheritic and, again, in most cases where death ensues after tracheotomy the patients die from septic infection of the air passages. In conclusion, therefore, those cases of diphtheria which present septic symptoms and those where tracheotomy may be required may with advantage be treated with antistreptococcic serum as well as with diphtheria antitoxin.

My best thanks are due to Dr. D. S. Davies, medical officer of health of Bristol and medical superintendent of the isolation hospitals, who always placed his laboratory at my disposal and was always ready to help me with his advice and to give me the benefit of his valuable experience.

Sikkim, India.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—It is hoped that the recent most successful ball at Covent Garden Theatre, organised by the Countess of Derby, on behalf of this deserving institution (the oldest so far as can be ascertained in the world), may be followed by a Waterloo Day Dinner during next season. Meanwhile, through the kindness of Mr. Charles Morton, anyone who is interested in seeing the erection of the new and enlarged hospital and is unable to spare time to cross Waterloo-bridge can see the building work now taking place on the bioscope at the Palace Theatre nightly about 11 P.M.

NOTES ON A CASE OF BACKWARD DISLOCATION OF THE HEAD OF THE HUMERUS CAUSED BY MUSCULAR ACTION.

BY C. W. MANSELL MOULLIN, M.D. OXON., F.R C S. ENG.,
SENIOR SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF CAMBRIDGE;

AND

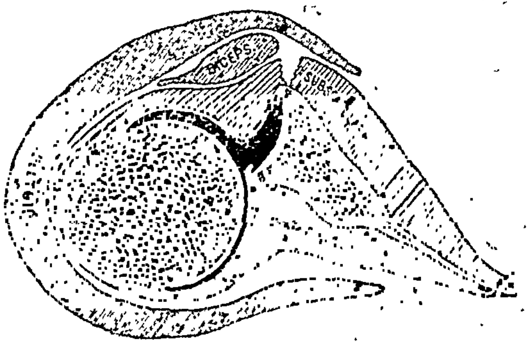
ARTHUR KEITH, M D. ABERD., F.R.C.S. ENG.,
LECTURER ON ANATOMY AT THE LONDON HOSPITAL MEDICAL COLLEGE HUNTERIAN PROFESSOR AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

BACKWARD dislocation of the head of the humerus is rare, but backward dislocation produced by muscular action alone is, so far as I (C. W. M. M.) know, unique. The patient who met with this injury was a rather stoutly built but muscular man of about middle age, who was playing tennis. Trying to take a ball breast high with a back-handed stroke he missed his aim and instantly his arm dropped by his side, useless, and he was seized with violent pain in the shoulder. Dr. C. Gould May of Cadogan-place, who was immediately sent for, diagnosed a backward dislocation of the head of the humerus and called me in There was no doubt as to the nature of the injury. The patient was sitting in the characteristic attitude nursing his elbow, which was flexed and pointing slightly forwards. The whole shoulder seen from the outer side had a peculiarly squared appearance. The arm was a little abducted and rotated inwards; there was a great hollow under the deltoid in front, so that the anterior portion of the glenoid fossa could be felt through the muscle, and there was a corresponding prominence behind. Active movement was impossible and any attempt at passive motion caused great pain. The patient was placed under an anæsthetic and as soon as the muscles were relaxed the arm was slightly abducted, drawn downwards, and rotated outwards. The head of the bone slipped in at once and there was no further trouble, the patient regaining perfect use of the arm in the course of a few weeks.

The mode in which this peculiar injury was caused is a matter of some interest. The head of the bone was caught behind the posterior lip of the glenoid fossa and held there. Probably the capsule was not torn or, at least, was not torn sufficiently to allow the head of the bone to protrude through it—an occurrence which, though not common, is not unknown in connexion with ordinary dislocation of the shoulder. The rapidity and the completeness of the recovery certainly favour this. The subscapularis was tensely stretched across the glenoid fossa and as soon as the head of the bone was dislodged by external rotation, combined with abduction and traction downwards, dragged it suddenly back into its place. The patient did not fall down or strike his hand or his elbow against anything, so that the displacement of the head of the humerus could not have been caused by leverage in the ordinary sense of the term. Nor can it be explained by sudden arrest of the momentum of the arm, for this would have carried the head of the bone forwards. The only explanation that appears to me to be feasible is that in the sudden knowledge that he had missed or was going to miss the ball, and perhaps in some way in an attempt to save the stroke, conflicting orders were sent down from the nervous system, the coördination of the muscles around the shoulder-joint, upon which its security depends, was improperly carried out, and the head of the bone was simply dragged directly backwards over the lip of the glenoid fossa by the violent and unopposed contraction of the short external rotators I am greatly indebted to Dr. Keith for having worked out so thoroughly the anatomy of this dislocation, and to Dr. H. Balean for the excellent illustration that he has made from Dr. Keith's preparation.

Anatomy of the Parts concerned in Subspinous Dislocation of the Shoulder, by DR. KEITH.

At the commencement of a back-handed stroke the humerus is rotated inwards, so that the anterior margin of the humeral head is in contact with the anterior margin of the glenoid cavity (see the points *a* and A in Dr. Balean's drawing). The subscapularis is then fully contracted and the anterior part of the capsule is thrown into a fold beneath the insertion of that muscle. The infraspinatus and teres minor are then relaxed but the posterior part of the capsule, which lies beneath their insertions, is taut and covers nearly two-thirds of the head of the humerus. In the rotation outwards which occurs in a back-handed stroke the posterior margin of the head of the humerus comes rapidly in contact with the posterior margin of the glenoid cavity (see the points *b* and B in Dr. Balean's drawing). During this movement the posterior part of the capsule, under the insertions of the infraspinatus and teres minor, is thrown into a fold, while the anterior part becomes taut over the anterior two-thirds of the articular head of the humerus. In the specimen from which Dr. Balean's drawing is made the subscapularis was cut across (i.e., thrown out of action), the infraspinatus and teres minor were kept on the stretch, and the arm was then rapidly rotated outwards. In this movement the head of the humerus, acting on the glenoid ligament (B in illustration) as a fulcrum, moved outwards and occupied the fold formed by the posterior part of the capsule, assuming a position similar to that seen in Mr. Mansell Moullin's case. The glenoid ligament is the representative in the shoulder of the semilunar cartilages in the knee and there seems to me to be a similarity between this form of dislocation of the shoulder and that of a semilunar cartilage of the knee. Because the knee ligaments are so strong it is the cartilage which is dislocated; in the shoulder, where the ligaments are so lax, it is the *bone* that is displaced.



Section through left shoulder-joint, looking towards hand.

70 CASES OF LOBAR PNEUMONIA:

AN ANALYSIS OF THE CLINICAL FEATURES AND POST-MORTEM CHANGES.

BY F. S. DAWE, M.D., B.SC. LOND.,
ASSISTANT RESIDENT MEDICAL OFFICER TO THE LONDON FEVER HOSPITAL; LATE ASSISTANT MEDICAL OFFICER TO KENSINGTON INFIRMARY;

AND

E. C. AUSTIN, F.R C S. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.,
LATE ASSISTANT MEDICAL OFFICER TO KENSINGTON INFIRMARY.

FROM January 1st, 1902, to March, 1903, inclusive we had at Kensington infirmary upwards of 70 cases of pneumonia with 29 post-mortem examinations. Many of the patients being older than the average hospital patient we think that it may be of some interest to publish a brief summary of these cases, of which we kept notes. With the exception of three or four cases that recovered in January, 1902, they include every case occurring in Kensington workhouse and infirmary during 15 months.

As to seasonal prevalence March to June were the chief months. There was no case in July but August, which was unusually cold, gave us five cases and October seven cases. The patients were chiefly males. 32 males and six females recovered and 21 males and 11 females died.

With regard to the portion of the lungs affected, in 37 cases that recovered and three cases that died without post-mortem examinations the physical signs pointed to the following: consolidation of the right lower lobe, 27; consolidation of the left lower lobe, eight; right apex, three; and both lower lobes, two. As to morbid anatomy, in 29 post-mortem examinations we found the right lower lobe consolidated in ten, the left lower lobe in three, the right upper lobe only in three, both lungs in four, the whole right lung in three, the whole left lung in four, and the left upper lobe only in two. If we add these together we obtain: right lower lobe, 37; left lower lobe, 11; right upper lobe, six; left upper lobe, two; whole right lung, three; whole left lung, four; and both lungs, six.

As to the relation of duration of illness to the nature of the hepatisation, in the St. Thomas's Hospital Reports[1] it is pointed out that the average duration of illness in those with grey hepatisation is only half a day longer than in those with red hepatisation, that in those intermediate between red and grey it is still shorter, and in the shortest illnesses of all grey hepatisation was found. The series consisted of 128 post-mortem examinations. It is suggested from this that grey hepatisation precedes red hepatisation in point of time. In our short series in the same way grey hepatisation was present in four out of five that died before the fourth day; on the other hand, those dying after the eighth day had grey hepatisation with one exception. The day of onset was known in 25: death before the eighth day, six red and 12 grey; death after the eighth day, one red and six grey. One with death on the twentieth day of illness had red hepatisation only. The factors in determining how soon red or grey hepatisation shall be established seem difficult to understand. It seems to have no relation to the age of the patient. The above 25 divide up thus: under 50, three red and eight grey; over 50, four red and ten grey. In two of our cases grey hepatisation had gone on to local gangrene.

The lymphatic glands at the bifurcation of the trachea were noted in 26 of the post-mortem examinations. They were enlarged in 17 and not enlarged in nine. In five the enlargement was limited to one side. In one of these curiously the enlargement was on the healthy side. Compared with other diseases on which we made post-mortem examinations these glands seem more often enlarged in pneumonia than in other diseases with certain exceptions, of which pulmonary tuberculosis is certainly one. For the sake of comparison we have tabulated our other post-mortem examinations.

—	Bifurcation glands affected.	Glands not affected.
Pulmonary tuberculosis	42 cases.	2 cases.
Diseases not thoracic	3 "	35 "
Broncho-pneumonia	5 "	3 "
Bronchiectasis...	1 case.	—
Chronic pulmonary congestion due to mitral disease...	4 cases.	6 cases.
Pericarditis	6 "	4 "
Empyema	2 "	—

The heart was always dilated. A white clot was noted in the right auricle and ventricle 15 times and was absent seven times. In pneumonia, as in all other post-mortem examinations, we very rarely found white clot in the left auricle. We, of course, do not know whether white clot is ante-mortem or not.

The following lesions in other organs were found in 29 cases: chronic interstitial nephritis and liver normal, 6; large white kidney and liver normal, 1; normal kidney and liver cirrhotic, 3; normal kidney and liver fatty, 4; large white kidney and liver fatty, 2; pericarditis, 2; pericarditis and endocarditis and empyema, 1; mitral stenosis, 1; pulmonary tuberculosis, 1; carcinoma of the uterus, 1; congenital syphilis, 1; diabetes, 1; and jaundice due to the pneumonia, 2. We had no case of meningitis although delirium was common, and coma occurred four times. Empyema occurred once in the cases that recovered.

Influenza preceded pneumonia, we believe, in five cases; of these three died. The case of pulmonary tuberculosis was in an early stage and no symptoms of this disease had occurred during life. Phthisical patients do not seem prone to lobar pneumonia. During last year 135 patients were under treatment for advanced tuberculosis of the lungs at Kensington These were exposed to abundant fresh air in special wards and some were left out in the open under an awning through the winter. No case of pneumonia occurred among them.

With regard to the prognosis in pneumonia in old age it is grave; in middle age it is dependent on the condition of other organs, especially the kidney, judging from post-mortem examinations; in youth it is good. In cases between 16 and 30 years, 16 recovered and 3 died; between 30 and 40 years, 7 recovered and 5 died; between 40 and 50 years, 6 recovered and 7 died; between 50 and 60 years, 5 recovered and 7 died; between 60 and 70 years, 3 recovered and 3 died; between 70 and 80 years, 1 recovered and 6 died; between 80 and 90 years, none recovered and 1 died. Below 50 years of age only two of the fatal cases were in sound health before the pneumonia, the post-mortem examination revealing a chronic lesion of some other organ in ten cases; chronic alcoholism was admitted in two more, and plumbism in a third. Above 50 years of age the prognosis in a man previously healthy is certainly graver, but even between 60 and 70 years in our fatal cases some other lesion was present in each one. After 70 years of age, on the other hand, of the ten deaths four presented no other lesion and three only a fatty liver. A chronic interstitial nephritis was present in the remaining cases. That we need not despair on account of age alone, however, is shown by the following case. A man, aged 72 years, had a crisis after a typical pneumonic attack. After this he developed a hectic temperature and became delirious at night. A few days later an empyema was detected. Dr. H. P. Potter drained this by incision without resection of a rib and by inserting a small tube. Recovery followed.

The text-books teach that sweating before the crisis is unusual: thus Dr. P H. Pye Smith says,[2] "Sweating during the height of the disease is uncommon and when present is not of bad import." In the present series it has not been very unusual and has been a good sign. 33 cases sweated before the crisis—seven died. 37 cases cases did not sweat—of these 25 died. In the 33, in over half sweating occurred throughout the attack on each day, but not the whole day. Sweating at the crisis occurred in nearly all. Sweating after the crisis only occurred once and this case nearly died from collapse at this time. Notes were taken from the beginning of this series in special reference to sweating.

Curiously enough, we only had one case of delirium tremens with pneumonia; this case recovered. It is, no doubt, the exception. The common delirium was an active one, trying to get out of bed being a common symptom, but without the hallucinations of delirium tremens. Mechanical restraint in such cases makes the prognosis much worse, we believe. 24 had delirium throughout part or all of the illness; of these, 14 recovered. 46 had no delirium and of these 25 recovered. The only case that developed delirium after the crisis for the first time had an empyema. In the majority delirium ceased with the crisis, but two had delirium before and after the crisis for two or three days. Authorities differ as to the prognosis of delirium; thus Dr. Pye-Smith finds only 15 per cent. of a series of 86 post-mortem examinations had delirium and regards prognosis as favourable. The St. Thomas's Hospital Reports, on the other hand, give out of 1142 cases of pneumonia delirium in 22 per cent. of the non-fatal and 49 per cent. of the fatal. Hence, in this series the prognosis has been influenced adversely by delirium. In our series the prognosis was only made slightly worse by delirium except when this occurred throughout the entire illness; of these cases half died.

In two cases coma was the first symptom; both died. In two others unconsciousness supervened during the last day or two of life and deepened into coma. We had no case in which coma was followed by recovery.

With regard to the extent of the lesion, double pneumonia occurred in six cases with one recovery. This man was the only teetotaler of the six—aged 44 years; the onset was influenza. The average age of the fatal cases was 51 years. The authorities differ on the prognosis in these cases. Dr. Pye-Smith and Professor Osler both regard the prognosis as worse in double than in single pneumonia; the St Thomas's Hospital Reports, on the other hand, show no increase in the risk of double over single pneumonia. They state that 10·3 per cent. of the non fatal cases were double pneumonia, 11·8 per cent. of the fatal were double, hence the risk is not raised appreciably.

---

[1] Vol. xix., by Dr. W. B. Hadden, Dr. Hector Mackenzie, and Dr. W. M. Ord.

[2] Clifford Allbutt's System of Medicine, vol. v., p. 119.

As to apical pneumonia, we had eight cases, with five deaths. In half there was no delirium. In the fatal cases the age and the other lesions present would have been sufficient to cause death whatever the extent of the pneumonia had been. Professor Osler thinks that apical pneumonia is not specially dangerous, nor does it belong to the cerebral type as a rule. Dr. Pye-Smith says that "apical pneumonia is no more prone to delirium than basic." The St. Thomas's Hospital Reports show "only 7 per cent. of the apical pneumonias had delirium." In spite of these statements in the text-books there is a common belief that apical pneumonia is usually of the cerebral type.

We think that the pulse-rate is of great value in prognosis. In our cases it was very rarely above 120 in those that recovered. Once it was 150 and in another case 140 with recovery. In those that died it was very rarely below 120 towards the end of the illness. We had no case of hyperpyrexia. The fatal cases included two in which the temperature was remarkably low. In one for ten days it was from 97° to 98° F., once reaching 99°. This case presented pericarditis and pneumonia at the post-mortem examination. A second case after six days' pyrexia had for 12 days a temperature of from 97° to 98° and then died.

The mode of termination was as follows: crisis in 29 cases; lysis in seven. The seventh and ninth days are the chief for crisis in our cases, the sixth and eighth days for death—that is to say, the patient dies on the day preceding what otherwise would be the crisis. Three days was the time usually occupied by lysis.

As to the diagnosis, in a typical case this is easy; in an atypical case it is by no means so. Seven times our diagnosis was made in the post-mortem room and once a diagnosis of pneumonia was proved to be mistaken. There is a class of case in which coma is the chief symptom and the treatment may be (erroneously) that for uræmia in consequence, as in the following cases.

A man, aged 35 years, convalescent from Bright's disease, had been up some days, when on Jan. 13th he lost consciousness suddenly while up; he remained unconscious for 24 hours and then came round. On the 15th his temperature rose to 100° F. On the 16th his temperature was 100° and urgent dyspnœa of a hissing kind began On the 17th there was gradual loss of consciousness ending in coma; the temperature fell. Death occurred on this day. Post mortem the upper two lobes were red and the right lower lobe was grey; the kidneys were small and white.

A man, aged 61 years, on May 15th fainted; he was admitted to hospital cold, blue, and giddy, but there was no pain. The heart was feeble. The lungs showed no signs of consolidation. There was no cough. Shortly after admission he became unconscious with stertorous breathing; he had incontinence of urine and repeated vomiting. The temperature was 102° F., the pulse was 140, and the respirations were 32 On May 16th he was still unconscious; the pupil reflex was present but the conjunctival reflex was absent. The temperature was from 103° to 104°, the pulse was 140, and the respirations were 42. The urine was suppressed, the breath was heavy, the skin was dry, and the chest signs were negative. Uræmia was diagnosed Strychnine, pilocarpine, and a hot pack were given. The urine passed was albuminous. There was some sweating in the pack; collapse followed and death ensued six hours later. Post mortem there was right apical pneumonia in the red stage; the heart was dilated; the kidneys were normal. We had two other cases of the same class.

Another type of case is admitted as a lunatic. Of this class the combination of delirium tremens and pneumonia is doubtless the most common, although not so in our series. We had the following rather curious case.

A man, aged 65 years, was sent in with an outside diagnosis of "bronchitis and mental," as he had picked up a knife to throw at another man. His temperature was found to be raised; there was crackling at both bases; and his temper was irritable. His six days' temperature was from 101° to 103° F., his pulse was from 120 to 128, and his respirations were from 36 to 40 The sputum was scanty and rusty; the skin was dry. Pneumonia was diagnosed Then followed 12 days' apyrexia. There was delirium for the last 16 days. The diagnosis of pneumonia was somewhat doubted during this time. Death ensued. Post mortem there was right apical pneumonia in the red stage.

Another type resembles acute tuberculosis.

The patient was a male, aged 16 years. He suffered from congenital syphilis. He had cough, wasting, and night sweats five weeks before admission. His breathing was harsh and there were abundant crackles on the right side; the right side was dull. The sputum was not rusty but muco-purulent. He was treated for six weeks, making 11 weeks in all. His temperature during this time was from 100° to 102° F. He had frequent sweats and there was progressive wasting. Tubercle bacilli was searched for many times; the result was negative, otherwise acute phthisis would have been diagnosed. During the last three weeks the sputum was offensive; empyema was now suspected, a needle was inserted and went into something of the consistency of liver and withdrew a little blood. The breathing was a little hurried. There was gradual exhaustion and death ensued. Post mortem in the right lung there was grey hepatisation with numerous patches of necrotic lung varying in size from that of a pin's head to that of a walnut; the right pleura was very thick, the cavity was obliterated, and the left lung had compensatory hypertrophy.

We had only one case of this kind. It shows the value of examining the sputum in cases that seem typical acute phthisis.

The only case in which rusty sputum was not diagnostic of pneumonia in our cases was the following.

The patient, a man, aged 71 years, was admitted for loss of flesh and strength. A low, irregular pyrexia persisted for upwards of a month. Cough was frequent. The sputum was rusty for 28 days and to within three days of death. There were dulness and weak tubular breathing in both posterior bases. Post mortem there was double hydrothorax; the lungs were a little compressed only; there was no pneumonia; the liver and kidney were cirrhotic.

When an elderly patient becomes slightly delirious at night and is noticed to be breathing fast he is more likely to have pneumonia than anything else whatever his temperature may be. He may, however, have pericarditis, especially if he has chronic Bright's disease When, on the other hand, an elderly or bedridden patient has a rigor and sudden rise of temperature to 104° F. he is more likely to have erysipelas than pneumonia It may be surgical kidney and in one case it proved to be perisplenitis at the necropsy. If the patient be an old soldier he generally tells you he has his old malaria again. This was not really so once in the 15 months at Kensington.

With regard to treatment, in these cases we tried to secure sleep by Dover's powder in the early stages, generally with some success and much to the patient's relief. In the latter part of the illness we tried, often unsuccessfully, to relieve the heart with leeches, strychnine, digitalis, and about three ounces of brandy. We did not see much benefit from doses of brandy above four ounces. We did not use oxygen.

In conclusion, we have to thank Dr. Potter, the medical superintendent, for his kind supervision of our work and for permission to publish these notes.

CANCER IN AUSTRALIA: A COMPARISON WITH OTHER COUNTRIES, TOGETHER WITH A SPECIFIC TREATMENT FOR THE PREVENTION AND ARREST OF THE DISEASE.

BY G. COOKE ADAMS, M.D., C M QU. UNIV., CANADA,
L.R.C.P., L R C.S EDIN.,
FORMERLY CHIEF OPERATING ASSISTANT TO THE LECTURER ON GYNÆCOLOGY, EDINBURGH MEDICAL SCHOOL.

(Concluded from p. 428.)

TREATMENT.

THE treatment of cancer may be divided into two classes—viz : (1) the preventive, and (2) the arrestive.

Preventive treatment.—Herein lies the only cure for cancer, as only by preventing or avoiding the exciting causes can we hope to diminish the increase in the disease and its progressive death-rate. From the results of my investigation and practical evidence in my own practice I have not the slightest hesitation in stating that I believe syphilis to be one of the greatest exciting factors in the cause of malignant disease. It is not too much to state that the majority of victims suffering from the effects of this disease, either acquired or inherited, have not received treatment for the necessary length of time to arrest the undermining of their tissues; and by the time they arrive at the cancer age their sad condition favours the development of malignant disease, more particularly in those who have inherited a malignant tendency. There is [illegible] in every country at an [illegible] we consider therefore [illegible] in discovering a successful treatment for arresting the ravages caused by this disease, also the length of time that has elapsed since the discovery was made, it amounts to almost criminal negligence on the part of those Governments, religious bodies, and faddists, who have deliberately delayed [illegible] their fellow subjects [illegible] disease.

[illegible] unate children who have inherited syphilis and are *daily attending our schools*, suffering day after day, year after year, their little brains, nervous systems, and general tissues being gradually undermined and ripening for such diseases as cancer, general paralysis, and other forms of insanity, while Governments and other public bodies look on hesitating to legislate, in spite of repeated warnings by nearly every section of medical science of the horrible results of this malady. Dr. Robert Jones, superintendent of the London County Council Asylum, Claybury, in a scholarly address on Development of Insanity in regard to Civilisation, delivered as late as July, 1903, at the annual meeting of the British Medical Association at Swansea, clearly points out the dire *effects of this disease upon the nervous system, thereby* causing general paralysis and other forms of insanity, and Dr. J. W. Ballantyne of Edinburgh has also pointed out that women suffering from syphilis at the commencement of pregnancy are usually unable to carry to full term and mostly abort before the seventh month unless specific treatment is begun early. It is not necessary to look far, therefore, for at least one, if not the greatest, cause of the decrease of population in the Commonwealth of Australia and other countries.

Syphilis for the same reason also is one of the greatest irritating causes of malignant disease of the uterus, repeated miscarriages leaving their dire effect on this organ by the time the menopause is reached—the most favourable time for the development of cancer. It is evident, therefore, that unless notification and treatment of this disease are made compulsory the prevention and cure of cancer and the other diseases named will be sadly hampered. Alcohol, sugar, beer, and sweet wines should be avoided by all those predisposed to malignant disease or by those who have a rheumatic and gouty tendency, and the two latter constitutional diseases should be carefully nursed during life in all those who have any *degree of cancer history*. The avoidance of all substances which cause constant local irritation is absolutely essential to prevent cancer. I think it is not saying too much to infer that the constant irritation for a long period of the corset in females is one of the principal exciting causes of cancer of the breast, even more so than excessive lactation, as is shown by its prevalence among females who have never suckled a child. If women will persist in using such an unnecessary and in *many cases fatal weapon let it be made in* such a manner that the breast will not hang over the front or in any way rest upon the same, as the constant friction on the breast caused thereby is doing gradual but sure mischief. Great attention should also be given by medical practitioners to the repair of lacerations of the cervix, the vagina, and the perineum, thereby avoiding the continual use of pessaries which no doubt from the constant irritation upon the lacerated and cicatricial tissue promote a susceptibility to cancer. *Circumcision should always be* performed upon those suffering with phimosis. The pipe should be avoided by those predisposed to cancer and bad teeth should be attended to. The native mode of carrying the kangri in India under the clothes, hanging on the abdomen, thereby causing kangri cancer by continual friction, should be done away with and another method of suspension insisted upon. The native habit of chewing the betel leaf should be discouraged as it causes constant irritation and cancer inside the mouth which *is so prevalent* among the native population of India.

The improved sanitary conditions of the people and large cities of Australia have apparently had an indirect influence in preventing the susceptibility to cancer in the majority of the native population. The fact that the general death-rate is much below that of any of the European states and is steadily declining is no doubt largely due to the methods of paving the principal streets of the cities with hard wood *blocks cut from the eucalyptus or gum trees*, also to the improved system of drainage. The antiseptic and other sanitary properties of the eucalyptus hard wood, apart from its excellent economical wearing properties, render it particularly suitable for street-paving and for building purposes. It should be largely taken advantage of in England and other countries as a means of improving sanitary conditions in the large cities.

Arrestive treatment.—The antidote or specific which I have no hesitation in saying is capable of arresting and preventing malignant disease and which has been a great success in my own hands is an Australian eucalyptus oil, to which for the purpose of distinguishing it from other *eucalyptus oils* the name "*mulyptol*" has been given at my suggestion. Mulyptol is an oil of a very high standard which is scientifically prepared from various species of the eucalypts *indigenous only to the Commonwealth of Australia.* It contains constituents possessing therapeutic properties which are not to be found in any eucalyptus oil obtained from any species grown outside of the Australian Commonwealth. It possesses not only the highest properties of the eucalyptus globulus oil but also valuable therapeutic properties which are *not to be found in this oil. Mulyptol*[1] *may be* relied upon as to the con [illegible] of its component parts [illegible] experience in the use [illegible] commerce was that they varied so much in this respect as to be absolutely unreliable to compass the results which I have recounted. The British Pharmacopœial requirements likewise afforded no protection, but, on the contrary, left many loopholes for adulteration by the addition of other deleterious agents. This nefarious practice is eagerly and unscrupulously carried out in this and other countries to such an extent with some oils that it renders prolonged internal and local administration (a necessity, as I maintain, in the successful *treatment of malignant disease*) absolutely dangerous. It is in my experience very necessary that the highest oxygenating and other valuable properties of the various species of the Australian eucalypts should be combined if the best results are to be obtained.

In order to make clear the foregoing remarks it is absolutely necessary that one should possess a little more knowledge of the chemistry and therapeutic properties of eucalyptus oil than can be found in the British Pharmacopœia or its excellent companions *or even any of the modern text-books on* materia medica or therapeutics. I may therefore be pardoned for giving the following brief description of the chemical constituents which are to be found in the Australian eucalyptus oils, many of which are the outcome of a scholarly research on the eucalypts of Australia, especially in regard to their essential oils, carried out by Mr. R. T. Baker, F.L.S., and Mr. Henry G. Smith, F.C.S., curator and botanist and assistant curator and chemist respectively to the Technological Museum *in the State of* New South Wales, Australia, and published by the Government of that State in 1902. The research in question covered an analysis of over 125 different species and too much praise and encouragement cannot be given to these able scientific workers who have well laid the foundation for therapeutists to discover the medicinal values of the chemical substances determined so far among which are the following:—

[illegible] d amyl.
[illegible] butaldehyde, valeraldehyde.
[illegible] (peppermint constituents).
[illegible] ne,
[illegible] and lævo-rotatory).
[illegible] l endesmate, valeric acid ester and
[illegible]

As many of the above constituents possess very valuable therapeutical properties, and as these are not to be found in *any one* of the species, it follows that the only method to obtain an oil possessing the full therapeutic properties of the eucalypts of Australia is to select a suitable one as a base and by a scientific *system of fractionalising* and distillation any of the above constituents may be obtained which possess any therapeutic value and can be added to the base oil, thus securing a more valuable oil than can be derived from any single species. To illustrate this more clearly: for many years the oil from the eucalyptus amygdalina was the most valued variety and was included in the British Pharmacopœia of 1885, but it is now excluded by the tests given by the British Pharmacopœia of 1898, owing to the fact that it contains a large amount of phellandrene, an irritating substance. Yet this species contains other valuable properties, such as eucalyptol, pinene, peppermint ketone, and traces of eudesmol. The oil from the eucalyptus globulus, the principal commercial variety, on the other hand, possesses no phellandrene and contains a fair amount of eucalyptol, therefore this oil has been largely adopted for experimental purposes and for internal administration owing to the fact that it possesses no irritating substances. This I perfectly agree with, but, on the other hand, although possessing valuable oxidising properties, it is very much more deficient in these than many oils from other species; for instance, it possesses only traces of eudesmol, a very valuable oxide found very largely in other species. It possesses no aromadendral, piperitone, and many other valuable constituents. Another very important fact is that the eucalyptus globulus is the only species that appears to have taken kindly to the soil of other countries where it has been transplanted, and I may state that I have tested the therapeutic properties of the eucalyptus globulus oils obtained from Italy, the United States, Algeria, Portugal, and many other countries and in every instance I have found that they do not come up to the standard of the indigenous eucalyptus globulus of Australia. The very fact that only one or two of the numerous species indigenous to Australia can be grown with any success in other countries and that they have been robbed of their indigenous soil should be sufficient proof of this statement. At the same time, I do not wish to infer that they possess no real therapeutic value but only that [illegible] are uncertain in action. Many of these are sold as [illegible] oils, therefore it is time such misrepresentation [illegible] official notice and the profession and public be [illegible] the foregoing remarks and brief description of [illegible] oils will be an answer to the following statement which appears in an official publication issued by the United States Department of Agriculture, Bureau of Forestry, Washington, 1902, entitled "Eucalypts cultivated in the United States," by Alfred James McClatchie, M.A., agriculturist and horticulturist of the Arozona Experimental Station, Phœnix, Arozona, which tends not only to deceive the medical profession and public but to injure severely one of the most promising industries in the Australian Commonwealth. The paragraph to which I particularly desire to draw attention appears under the heading "Uses of the Eucalypts," p 39: "The medicinal properties of the various component parts of the eucalyptus oil differ widely. Hence the oils from different species have very different medicinal values. Unless eucalyptol, the chief ingredient of the blue gum oil, has the same effect upon the human system as phellandrene—the prominent ingredient of the peppermint tree oil—the oils from these two trees must necessarily have different medicinal properties and the oil from a forest of mixed species must have very uncertain medicinal properties. The eucalyptus oil produced in America, where the groves from which leaves are obtained for oil are commonly of one species and where with rare exception a single species (blue gum) is the source of all the oil extracted, will necessarily be a produce whose properties are better known and more constant than that produced from mixed native forests. *Hence the importation of eucalyptol or eucalyptus oil from Australia or elsewhere is both unnecessary and a disadvantage to the consumer.*" (The italics are mine.) I may here state that I have recently brought the matter under the notice of various agents-general of the States of the Commonwealth, suggesting that all eucalyptus oils manufactured in Australia should be inspected and certified to by the various Government State analysts, defining when possible the species from which the oils are manufactured and that they should also receive the Government stamp in order that the medical profession and public may rely upon having an Australian eucalyptus oil manufactured from Australian indigenous foliage and not from the eucalyptus foliage of another country.

---

[1] "Mulyptol" is prepared by the Australian Eucalyptus Chemical Company, 18, Mansion House Chambers, Queen Victoria-street, London, E.C., from whom it may be [illegible]

Sanitary properties.—The late Baron von Mueller, F.R.S., K.C.M.G., M.D., &c. (Government botanist of the State of Victoria), in his masterly work, "Eucalyptographia," makes the following statement: "The sanitary influence of the eucalyptus vegetation was surmised by more than one of the early Australian settlers, who were reluctant to place their conjectures on public record without positive investigation and final proof." He further states: "The incontestable sanitary effect of these prevailing myrtaceæ throughout Australia, except in some of the tropical coast tracts, must be ascribed to a complex of causes: (1) the ready and copious absorption of humidity from the soil by eucalypts and closely allied trees; (2) their corresponding power of exhalation much greater than that of many other kinds of trees; (3) especially the evolution of a peculiar highly antiseptic volatile oil; and (4) the disinfecting action of the dropping foliage on decaying organic matter in the soil, eucalyptus leaves themselves not causing any noxious effluvia through their own decomposition." The disinfecting and deodorising virtue of the tree being unquestionable, it was placed by Dr. Mosler and Dr. Goeze of Greifswald and Dr. A. Buettner of Melbourne in the wards of hospitals.

The germicidal properties of the eucalyptus globulus oil have been the subject of much research. Dr Bucholtz has shown that as a germicide it is of three times the strength of carbolic acid. Dr. Omelchenko's experiments have proved that the vapour of eucalyptol does not destroy bacilli so quickly as that of the oil of eucalyptus itself, the former taking 134 hours to kill the bacilli of anthrax while the latter only took 72 hours to destroy them. Mr. Th. Taylor found that albuminous compounds could be preserved in water which by maceration of leaves of eucalyptus globulus had absorbed some of their oil and perhaps other preservative particles, a few drops of the oil added to water serving the same purpose. Other kinds of volatile oils act very variously in this respect. He also observed "that it may be injected into veins and arteries of cadavers for purposes of preservation." Eucalyptus oil will preserve flesh of any kind as well as creasote. Beef sprinkled with it will dry hard without putrefaction. Mr. Taylor attributes its hygienic action to its high oxidising power as exemplified in the decomposition of miasmata.

It was through His Grace Dr. T. A. Goold, R.C. Archbishop of Melbourne, that the plantations of the eucalyptus globulus were first established for subduing the miasmatic exhalations of the Pontinian swamps, and this prelate, writing to Baron von Mueller on Dec. 17th, 1879, says: "It was first raised in the Campagna from seeds kindly presented to me by you on my visit to Rome in 1869 to attend the Vatican General Council. I handed the seeds to the superior of the Trappist monks who then occupied the monastery and grounds of the Tre Fontane, a most fever-stricken locality. On my next visit to Rome, made a few years later, I had the pleasure to see the good results of your kind and thoughtful presentation in the vigorous growth of many gum trees acting most wholesomely on the poisonous air of that part of the Campagna."

Therapeutic properties.—The first positive experiments upon the febrifugal virtues of leaves of eucalyptus globulus were made by Dr. Tristan in Spain and were published in the *Compilator Medico*, 1865. Dr. Tristan's observations were subsequently confirmed after grave clinical research by Dr. Adolph Brunel of Toulon, Dr. Carlotti and Dr. Tedeschi of Corsica, Dr. Gimbert of Cannes, Dr. Mares, Dr Bertherand, and Dr. Miergues of Algeria, Professor Lorniser of Vienna, Dr. Caston of Montpellier, Dr. Sacchero of Sicily, and many others, all of whom have placed the antifebrile properties of eucalyptus oil beyond a doubt. The success achieved by Mr. J. B. Curgenven in the treatment of scarlet fever; Dr. J. C. Voight, Mr. L. Kesteven, Dr H Bengafield, who will appear to believe it is a specific in typhoid fever; Dr. Voight, Sir John Cockburn, Dr. Bengafield and others, in diphtheria and croup; Dr. B. Ball in the treatment of phthisis uses hypodermic injections of eucalyptol and believes it counteracts the septic phenomena of the malady, as does Dr. Conas[2] in the treatment of certain pulmonary affections, such as chronic ulcerative phthisis and pulmonary catarrh. In gangrene, ulcerative diseases of the bladder, bowels, nose, and ear, gonorrhœa and syphilis, various applications have proved very beneficial. My first use of eucalyptus oil was in connexion with my gynæcological operations, having adopted it early in 1893 as my only antiseptic, owing to its non-irritating, non-poisonous, deodorising and already proved highly antiseptic properties. All dressings used in connexion with my work were prepared from this oil. It was therefore the success achieved by its use in these operations, particularly in the treatment of accessible malignant lesions, that prompted me to investigate its actions internally, particularly with a view of still further testing its power of arresting the progress and process of the disease by preventing and arresting secondary deposits and recurrence.

---

[2] Medical Record, June 15th, 1887, p. 254.

The following is a summary of the cases treated, with results and some observations upon the same. The majority of cases of malignant disease in which I have used eucalyptus oil ("mulyptol") internally and externally were cancer of the breast and uterus. The whole of the 55 cases previously referred to were treated by this means only, operative treatment having been refused. In the majority of breast cases the tumour varied in size from that of a hen's egg to that of a goose's egg. All were in a state of proliferation and degeneration, showing more or less general œdema of the cellular tissue over the breast. In most of the cases there was superficial ulceration, the skin being adherent to the subjacent tumour, and with the exception of five cases the mass was not moveable at the commencement of treatment. In all cases the glands along the pectoral muscles and in the axilla were enlarged, most cases showing swellings in the neck along the anterior border of the trapezius muscle. With the exception of eight cases the arm corresponding to the breast in which the cancer developed was painful, tense, œdematous, and swollen almost down to the wrist. In 11 cases the nipple was flattened and in the remainder there was more or less retraction of the nipple. Emaciation was present in all cases and in 25 decided cachexia. The average time in which the disease was first noticed until treatment was begun was from three to six months. In all cases the treatment was carried out for a period of from six to 12 months under my personal supervision and directions, therefore a definite statement can be given as to the benefits derived from the treatment, and though inquiries were made for periods of from two to four years after treatment was discontinued in not one instance was recurrence reported. The following was the treatment invariably adopted. The internal treatment, which was administered simultaneously with the local treatment, consisted of the administration of mulyptol either in the form of emulsion or gelatin capsules. I generally began by giving five-minim doses every four hours after food for the first week, gradually increasing to ten-minim doses by the end of the second month. In addition to this administration the pure mulyptol was applied by means of inunction, being rubbed into the axillary and abdominal regions morning and evening, and inhalations were administered twice daily in the following form: mulyptol, 80 minims; light magnesium carbonate, 15 grains; and water to one ounce; a teaspoonful in half a pint of boiling water. In cancer of the breast the external treatment was as follows. After washing the breasts and glands with a warm emulsified solution of mulyptol, particular attention being given to the nipples, the cancer breast was vaporised for from 15 to 20 minutes, dried, and a piece of lint, which was kept soaked in a solution (1 in 4) of mulyptol and olive oil, was placed on the breast and covered with oil-silk dressing and a firm bandage applied. As soon as all crusts which were present had been removed several dressings of lint soaked in pure mulyptol were placed over the growth and usually after a week of such treatment the nipple and other ulcerated parts appeared to have taken on a raw but healthy appearance. Daily dressings of mulyptol and olive oil (1 in 2) solution were continued throughout the treatment. The breast became red and swollen for the first two weeks, due, no doubt, to a condition of leucocytosis, but from this onwards there was a subsidence in the general infiltration and by the end of the first month, under a condition of fibrosis, the growth was found to have diminished considerably in size and had become more freely moveable. Th [illegible] -lution of m [illegible] were all th [illegible] results ap [illegible] found on an average that by the end of the fourth month all signs of the growth and malignant condition had disappeared and the beneficial effects of the treatment were apparent. The enlarged axillary glands and the glands in the neck had disappeared and in most cases the adherent skin had become soft and more supple. In cases of cancer of the uterus the above internal medication was adopted; in addition to which the breaking down surface of the cervix and invaded parts was painted every alternate day with pure mulyptol, vagina packed with a long strip of mulyptol gauze. This dressing was removed in 24 hours, a warm mulyptol douche administered, and a tampon of cotton-wool soaked in a solution (1 in 2) of mulyptol and olive-oil or glycerine applied. The cervix and ulcerating parts very soon took on a healthy appearance, all fœtor and decomposition being checked, and a gradual but sure arrest of the pathological progress and process of the disease was accomplished. In addition to the above treatment in some cases daily local vaporising by means of hot mulyptol sitz baths was found to be particularly beneficial at the outset, especially in those cases where a rapid degenerating process of the disease with much hæmorrhage had been going on prior to commencing treatment. Treatment was persevered with for from three to six months after all signs of malignant disease had disappeared.

It is very important to observe the stages in the progress of the patients towards recovery by means of the foregoing treatment. During the first two weeks a leucocytosis in the local lesion is produced, and the first improvement appeared to be in the local lesion when ulcerated taking on a healthy healing surface, with signs of a subsidence in the general infiltration, and by the end of the first month a marked diminution under a condition of fibrosis in the size of the growth was noted and the glandular enlargements had considerably lessened. In the breast cases general œdema of the arm and intense pain had almost disappeared by the end of the first month and the above improvements were much more apparent. There was a more healthy appearance in the general condition of the patient with a slight increase in weight. This gradual improvement is noted throughout the treatment. I desire to state that the improvement, although marked, is slow for the first two months, after which time it becomes more rapid; of course, this is all according to the stage of the development of the disease at the time treatment is begun.

As the majority of malignant cases which I have treated have been disease of the breast and uterus I would suggest a trial of the aforesaid internal treatment for all cases of malignant diseases. The local treatment, of course, would be varied according to the locality and nature of the lesion. Thus, in cheek, tongue, throat, and nose cases daily atomising and vaporising should be persevered with, together with daily applications of pure mulyptol itself to the local lesion and also with daily inunctions with the oil. I may here state that I am at present treating several cases of cancer of the cheek and tongue with mulyptol and its various medicinal preparations and dressings with very gratifying results, and of these I intend giving full details at a later date. For malignant disease of the rectum, rectal injections of half-drachm doses in solution (1 in 4) of olive oil or in the form of suppositories may be added to the treatment. I have also found that hypodermic injections of mulyptol in from five to ten minim doses in liquid paraffin were very efficacious in many instances. Hypodermic treatment should be confined to the abdomen, the oil being rapidly absorbed into the system. I frequently begin treatment by hypodermic injection into the growth when hard and deep seated. For internal or inaccessible malignant diseases the internal treatment must be suited to the particular case and locality of the disease. Capsules or emulsion, rectal injections and inunction, together with daily inhalations are suggested. In hospital treatment the wards should be daily washed with mulyptol disinfectant solution and oil sprinkled about the beds. Mulyptol and its preparations might supplant all other antiseptics in malignant surgical treatment, being non-irritant, non-poisonous, and fulfilling all the needs of a general antiseptic.

Before concluding, it is necessary to consider the mode of action of eucalyptus oil when given internally. It acts as an antiseptic. Cases are recorded of tuberculous bacilli having disappeared under its treatment. Numerous cases of diphtheria and typhoid fever have been rapidly cured under its internal administration, from which results it would appear that it possessed a specific action either directly on the bacilli or by rendering inert their toxins. In malignant disease there is every evidence of its having a specific action on the local lesion itself. It acts in removing and relieving co[illegible] by promoting rapid absorption. [illegible] are already well known, the [illegible] r, according to Kesteven[3] a[illegible] in 14 days.

---

[3] Eucalyptus in Typhoid Fever, Practitioner, Ap[illegible]

on the general nutrition of the body, evidence of which is given by the increase of weight. This is probably due to the fact that it possesses a power of raising the nutritive force, thereby increasing the vitality of the tissues to resist the action of any specific toxins which may be present. The chief interest, however, lies in its internal administration, as no other antiseptic or drug possessing germicidal properties can be given in such large doses continuously and for such a length of time as eucalyptus oil. Dr. Voight in fever cases administers drachm doses by rectal injections (1 in 4) of warm olive oil, repeated at frequent intervals when the temperature is high. He finds its antiseptic action very beneficial in cutting short an attack of influenza and in preventing the general breakdown and nervous phenomena usually following this disease. Its non-irritating and non-poisonous properties render it particularly serviceable for inhalation purposes. Dr. A. Irsai of Budapest by his laboratory research on the inhalations of various substances shows that eucalyptus globulus oil can be inhaled into the lungs and finest air passages without any fear of irritation. He found that oleum juniperi, oleum terebinthinæ, and oleum pini sylvestris irritated the lungs by setting up a condition of spasmodic contraction of the pulmonary vessels, the oleum pini sylvestris doing so especially. On the other hand, he found that *guaiacol and creasote set up rapid relaxation of* the vessels and great hyperæmia of the lungs, and he stated that it was needful to exercise due vigilance in employing these where there was any tendency to hæmorrhage.

As it has been proved that any prolonged irritation is liable to set up malignant disease it is evident that such treatment as the x rays, Finsen's light, and applications of irritating drugs and caustics is strongly contra-indicated, for even should the primary lesion be temporarily improved thereby the continuous irritation on the surrounding tissues is almost sure to favour extension or secondary lesions. Far better is early and prompt removal, or if this is not permissible then local treatment should be decidedly of a non-irritating and non-poisonous nature. This I claim for the treatment suggested in this article, used either internally or externally, and I can confidently recommend it to the profession with every prospect of success in the arrest of malignant disease.

Summary —The positive conclusions at which I have arrived as the result of this investigation are as follows: (1) that cancer is not due to a bacterial or parasitic origin; (2) that cancer is a constitutional disease due to a specific or malignant virus originating in the blood and chiefly manifesting itself after 35 years of age and at its greatest virulence between 50 and 70 years of age; (3) that malignant disease may be congenital and certain forms acquired by infection or contagion; (4) that the principal factor in the cause is hereditary tendency; (5) that the principal exciting factor is prolonged local irritation acting on a constitution suffering from an inherited tendency or which has been debilitated through want of treatment of one or other of the following diseases in their order of frequency: syphilis, alcoholism, obesity, rheumatism, gout, or tuberculous disease; (6) that the principal dietetic factors in the cause are sugar, beer, and alcohol; (7) that the principal hygienic factors in the cause are woods and forests whose dropping foliage decomposing causes stagnation of water; also badly formed streets and defective drainage in cities, and the overcrowding, badly housed and fed population of cities; (8) that cancer is a preventable disease and the absolute cure is only to be found in the means for preventing its exciting causes and completely removing the same; (9) that the sanitary indigenous foliage of the following natural orders—(*a*) myrtaceæ, (*b*) lauraceæ, and (*c*) coniferæ—appears to exert a specific influence in rendering the native born population of the countries where they grow almost immune from malignant diseases other than might be caused by prolonged local irritation (the Australian eucalypts belonging to the myrtaceæ exert the greatest influence in this direction); (10) that a eucalyptus oil obtained by means of a scientific preparation from various species grown in Australia possesses a specific action in arresting the pathological progress and process of malignant disease; and (11) that all internal and local treatment of a poisonous or irritating nature should be absolutely avoided, more particularly such local treatment as the x rays and Finsen's light, as they are likely to set up secondary conditions around the site of lesion. Far better is early and prompt removal when the malignant growth is accessible. My object in writing this article is to throw some further light on the cause of malignant disease and to bring more prominently before the notice of the profession a remedy which, though known in some degree, is in my experience insufficiently known and certainly insufficiently appreciated. And whilst strongly advocating its more general use in the treatment of wounds and specific fevers, &c., it is in relation to its specific effect as applied to the disease of cancer that I would urge the profession to give it a fair trial.

Welbeck-street, W.

CÆCAL CONCRETIONS.

BY ALEXANDER FORSYTH, M.D. GLASG.

ON Jan. 20th, 1903, Lord Lister wrote to me: "I trust you will not long delay the publication of your experience with the concretions and their relations to appendicitis." The subject was not in his line when he was in practice but he showed great interest in my views and in a typical case of cæcal concretions. The subject has grown since then till it far exceeds the limits that the Editors of THE LANCET can deal with. I therefore on their advice propose to lay my position before my fellow practitioners and to ask them to give their personal experience on the subject and to put my practice to the test.

My first and fundamental proposition is that the cæcum contains about two pounds of concretions. I have recognised these concretions since 1886. Before that I had occasionally met them and wondered where these decomposing masses had been hidden after all the other decomposing matter had been got rid of and the patient was now passing healthy motions, but could not answer satisfactorily. In 1886, however, I was called to see a widow, aged 33 years, whose sister was alarmed at her "wandering in her mind." She had delusions and illusions, thought that she had been visited by friends but had not, asked me why I had not called on her yesterday which I had done, and saw rats running over her bed and picked at insects, &c., on the counterpane when there were none. A clear mouth-*to*-anus passage was obtained after a long course of enemata, &c., but no improvement followed. Then her sister showed me a large "peculiar" fœtid motion which she had washed out, consisting of hardened but not quite dry concretions packed together with suggestions of the shape of their receptacle. The only place which they could have come *from* was the cul-de-sac of the cæcum, below the ileo-cæcal valve, through which fresh fæces had passed *over* it. From the very day they were voided the mental symptoms ceased and convalescence set in. The contents in this one case seemed wholly injurious and some active process of sulphuretted hydrogen formation was indicated.

I followed up the lesson I learnt then and proved its use in numerous cases since. Under the name of "loaded cæcum" I recognised a pre-typhlitic stage and treated it successfully in every case—that is, I avoided the later and more dangerous conditions from the appendix complications. The general types of my cases may be given as follows.

The first type are women who live a quiet and uneventful life. They bear the marks of sorrow and anxiety in their faces and deportment. They are distinctly melancholy but cannot be described as hypochondriacal. Emaciation of the body is distinct. They have no life, no jollity at all, though their years may not be great or their social condition unsatisfactory in any respect. They are aged before their time and look gloomily on everything and everybody. A widow, aged 69 years, who was seen in 1892, was one of this type who seemed to have her life brightened and prolonged by clearing out the cæcal concretions. After six weeks' persevering work the apparently interminable "bilious stools" were followed by well-digested "baby motions," the cæcal concretions were got at and cleared out, and her mental and physical oppression disappeared. The deep furrows in her face and forehead cleared away, her cheeks filled up, and she threw ten years off her shoulders.

The second type is fully represented by a class of young, healthy men who very unwillingly give way to sickness but who have quite their share of illness from loaded cæcum. Under the name of "constipation" and the temporary relief afforded by aperients they keep about their work with the same saddened, anxious faces and malnutrition of the body that are present in the other sex. In them also clearing away a couple of pounds of cæcal concretions changes the men in spirits and health permanently. I refer to police officers whose tours of duty are one month day work and next month night work.

In one case in point the following record was given. On July 10th, 1897, he was attacked with "appendicitis" which lasted for 26 days. On Dec. 22nd of the same year he was seized with "abdominal pains," being ill for 20 days. On Nov. 2nd, 1898, "dyspepsia" came on and lasted for 18 days. In 1899 he suffered from "constipation" for 19 days. On July 11th, 1899, he was again attacked with "appendicitis" which lasted for 91 days. This long list means that the man was not cured till the last occasion. The shorter treatment permits only of clearing out the colon and removes one of the two conditions necessary to so-called appendicitis. The patient is *therefore safe for the present. But the cæcal concretions* remain, the colon gets blocked again, with a return to the sick list. He called on me in February, 1903, and his account of himself is worth recording.

On the first occasion (July, 1897) he went to St. Thomas's Hospital, where he "lay in bed for a week and had milk and castor-oil only." The last time (July, 1899) he was under my care as his divisional surgeon. "I was in a terribly weak state and walked about in misery always. I was always tired and wanted to lie down; always in very low spirits. I felt regularly weak; knocked up. I could not eat or drink anything; if I did I brought it up. I don't want to have a bout like that again." Persistent enemata with large doses of olive oil taken internally two or three times daily constituted the treatment. The concretions began to come away in about six weeks. I continue his narrative. "The stones came away nearly white, about the size of a pea, and a lot of phlegm-stuff with them; a good many of them at different times, loose in the injections, always floated, soft looking" (the effect of the oil); "I never touched any food till they came away. They were coming away for a week or a fortnight. I should think quite a couple of pounds. I never felt ill since and had no return of the stones (i.e., over three years). I am quite different. I can eat and drink anything and enjoy a good dinner and do a bit of gardening." He looks plump and cheerful and he still retains his vermiform appendix.

A third type is constantly obtruding itself on the general practitioner and calling for his help. It includes the large class suffering from "windy spasms." It might be called the "borborygmous type." The following is a case in point.

The patient, a married woman, aged 38 years, was a strong, active, well-nourished person engaged in a very trying business. Her abdominal girth was so great that she had not been able to stoop. It was so obtrusive and obstructive that [illegible] be carried on at a con- [illegible] s also were coarse and [illegible] from wind, pain in the descending colon and above it, constipation, frequent faintness, palpitation, bre [illegible] fear of impending death), [illegible] great as to drive her [illegible] stimulants. Two years ago I told her that she could be cured only by submitting to a six weeks' course of treatment to empty her cæcum. But this did not commend itself to her. She had only palliatives and temporary relief from aperients from many sources. At last, on March 21st, 1903, she was so very unwell and low-spirited from her continual ill-health that she asked me to undertake what I had so often recommended, hoping that I might not require six weeks. I told her the probability now was that a longer time would be required to finish the work, more likely three months, but in any event she was to permit me to finish it and then I promised she would be free from her constant illness.

The case is of great interest in many ways and I kept an account of my daily work but will here give only a few extracts. The colon was choked from beginning to end with a large cushion of sulphuretted hydrogen saturated, hard, fusiform fæces. On April 22nd, after a month, she could feel the warm enema trickling up and across and, when she turned on her right side, down the colon to the cæcum. A few whitish specks like "curdled milk" (mucin) appeared floating on the surface of the returned enema. She had observed it two or three times already. I promised her a closer and larger knowledge of them before long. On the 25th she had a clear, free drain-pipe (the colon) that would carry off any amount of gas (34 days). On the 27th I was greeted with the following: "I had such a lot of very funny stuff come away after you left on Saturday (25th), a lot of white jelly stuff, clear, and the pieces as big as the top of that bottle (two inches in diameter). I never had such stuff come from me and such a lot of it." I reminded her of my promise of the 22nd that she would see much more of the jelly. My previous case had drawn my attention to this jelly where the surface of the water had been covered with a layer of pieces like "curdled milk," which pieces the microscope showed to be mucin with its numerous variously shaped "goblet cells." Occurring again here and seeking for its meaning I could only think that the jelly had stood between me and the concretions, forming a pellicle over them which the stream of water had broken up and washed away, then only allowing me to act on the old, hard, dry concretions. When I had entirely got rid of these (in 37 days) on May 26th my opinion was strengthened by a similar pellicle coming away whole and *with a tail hanging from it in the shape and* position of an appendix. On the 26th the following note was made: "Enema brings away an empty bag in the shape of the end of the cæcum with a prolongation like an appendix but much larger." There was no sign of abscess or inflammation in all this and the pyogenic-looking membrane was a tough protecting layer with probably a physiological function rendering these old concretions harmless. The membrane was accompanied by some dozen or less small typical concretions, *fresh* for the first time. (65 days passed before the appearance of fresh concretions.) The cæcal contents had been open to attack from the time the large jelly stool appeared on April 19th, 27 days after commencement of treatment. Therefore the actual washing away of the cæcal contents required 37 days.

As the case progressed the patient's facial lines became *finer, her protuberant abdomen receded, and she could stoop* when she was reduced to 52 inches, about half way through the treatment. On May 27th the following note was recorded: "A special interest in this case was the persistent hardness and dryness of the cæcal concretions, never to the end coming away in masses like most others." On June 20th the bowels had acted two or three times every day without aperient—"a baby's really." The patient felt better, could talk better, think better, and for the first time acknowledged the complete benefit which she had derived from this long anxious work. She said that her husband also saw it as did all her friends.

There is a class of cases, the largest of all, from which I expect the most striking evidence of benefit from this treatment. I have not had the opportunity of putting my practice to the test in this field, but as a district medical officer since 1868 I have had *only too ample means of forming an opinion* and that is one of dissatisfaction with the constant march of so many, young and old, to lunatic asylums. I know the profound effect on the mind produced by a loaded cæcum and the return to mental health when it is emptied. I have seen [illegible] by it only and stopped by the [illegible] on also seems to be the only [illegible] in puerperal eclampsia and I recall cases of lunacy where now I would adopt this treatment before filling up the certificate. May not some, many of the thousands of patients in these asylums, be benefited by this treatment? The delusions in the first case would have warranted a certificate: emptying the cæcum dissipated them. The medical officers of asylums have an ample choice before them; I ask them to help on the inquiry. It is worth while emptying the cæcum.

NOTES ON THE ETIOLOGY OF LUPUS AND ON CASES TREATED BY THE X RAYS AND FINSEN LIGHT.

BY FRANK H. JACOB, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS AND TO THE ELECTRICAL TREATMENT DEPARTMENT, NOTTINGHAM GENERAL HOSPITAL.

I HAVE attempted to work out the personal susceptibility and also the actual source of infection in 30 cases of lupus under my care with the following results. In 22 of the cases there was a history of phthisis in near relatives, while in eight no such history could be obtained. In three cases the lupus appeared while the patient was actually nursing a case of phthisis and in one while nursing a [illegible] of hip with a discharging sinus. In three cases lupus appeared in an infant whose parent was suffering from phthisis and in one case the father had died a year previously from phthisis. One patient habitually used the same towel as her sister who was suffering from lupus. In two cases the disease arose on the wrist of a patient suffering from phthisis. In one case it arose from the margin of a wound left after excision of glands in the neck and in two cases it arose from the margin of a chronic abscess in the neck. In one case it occurred in the wound caused by a blow over the tibia. Thus in 15 cases the origin could be traced with tolerable certainty. In addition I may mention that six cases presented blocking of a nasal duct previously to the appearance of lupus of which cases four were probed prior to the onset of this disease.

Treatment of the cases of lupus.—The treatment which I now believe to be the most efficacious is as follows. For extensive cases the x rays should be applied as a routine treatment for ten minutes three times a week. I aim always at producing a mild reaction, as in my experience a reaction leads to a more rapid result. For special cases modifications are necessary. For example, I have one patient the whole of whose face (except the forehead), left arm, left foot (except the sole) and leg up to the knee were affected with rapidly spreading active lupus; that on the face was of the superficial plaque variety; on the arm and leg it was likewise of the plaque variety but deeper. the dorsum of the fingers showed a markedly verrucose condition, the leg was very much thickened, and the dorsum of the foot was ulcerated. The face, arm, and leg were each treated twice a week with 20 minutes' exposure on each occasion. Now, after two years' treatment I can only find on the face two small areas close to the ear of about the size of a threepenny-piece, on the arm no lupus at all, on the leg a few small areas close to the knee, the thickening is markedly less, and the ulcer has long ago healed. These few peripheral portions are now receiving special attention and will soon be cured. Another patient lives a long distance away and is moreover very poor, consequently she is only able to attend at intervals varying from four to eight weeks; she then stops a week-end with relatives in the town and has 20 minutes' exposure on Saturday, Monday, and Tuesday. This causes a distinct reaction. She had originally a very thick patch on the left cheek of ten years' duration, about two by one and a half inches in diameter. After 18 months' treatment she is now almost cured, there being just a little very thin lupus at the upper margin.

For ulcerated septic cases the x rays have proved most admirable, cleaning and healing being completely established in from four to eight weeks; the subsequent curing of the lupus of course takes very much longer.

Deep nodules formerly gave me considerable trouble as they were apt to persist when the more superficial portions had entirely disappeared. In my cases the deepest nodules have been situated in the centre of the cheek and in the cartilaginous portion of the nose. I now treat them as follows. With a wooden match I place a small drop of pure phenol on the top of the nodule; when the surface is thoroughly anæsthetic I penetrate the nodule with a pointed match dipped in pure carbolic acid and when the deeper portion is also anæsthetic I thoroughly rub the carbolic acid into the nodule, then while the part is still white from the carbolic acid I apply the Finsen lamp (London model), limiting its action to the area required in order that I may induce a somewhat severe reaction without unduly punishing the patient. This repeated some three or four times is usually sufficient to establish a cure. The disadvantage of this treatment is that it is liable to leave small pits.

I treat *small limited areas* in the same manner as the deep nodules, in some cases producing a reaction with the x rays instead of the Finsen lamp The result is very satisfactory and the most rapid with which I am acquainted.

Rodent ulcer.—It is an advantage of life in a small town that one is able to trace the after-history of cases with more readiness than is possible in London. This after-history shows recurrence to be extremely frequent; this is, I believe, due in a great majority of the cases to insufficient treatment. Inasmuch as the disease is not the ulcer but the new growth it is obviously necessary to continue treatment until every suspicion of new growth has disappeared and if this be rigorously carried out I believe that recurrence will become as rare as it is now common. There is, however, another cause of recurrence—viz., that the ulcer is due to a true carcinoma of the skin and is not a rodent ulcer. I have one such case with deep excavation and very thick hard margins, which though once healed by the x rays recurred and has progressed rapidly in spite of treatment.

Eczema.—Two cases of eczema of the palm have been treated by the x rays; they both presented great thickening of the horny layer of the epidermis, which was traversed by deep bleeding cracks; for eight years one, and for seven years the other, had been unable to perform even light household duties such as dusting. The first case after six months' treatment was completely cured and now remains after three months without a relapse, though she does her own scrubbing. The second case was cured by one month's treatment, the diminished length of treatment being due to my experience of the first case having taught me that the necessary factor in the treatment was to produce sufficient dermatitis to cause active desquamation.

Ringworm.—It was in July I first treated ringworm by depilation by means of the rays; since then my aim has been to reduce the number of exposures necessary to obtain depilation to the minimum and to produce it without any reaction, for my experience with lupus in hairy parts taught me that no trace of reaction is necessary for this purpose. With my apparatus I can accomplish this by two applications of half an hour each at intervals of a fortnight. I am now aiming at depilating only the affected hairs and in one case I have, I believe, effected this.

Lupus erythematosus.—I have only completed treatment in one case and that a chronic patch of the sebaceous type of eight years' duration occurring on the nose. This has now been completely cured for four months and shows no indication of relapsing.

With respect to apparatus, the essential point is to know your own plant, more especially your tubes, and when in doubt to try them on yourself, so that you may be certain of either not producing a reaction or inducing that degree of dermatitis which you may desire without risk of producing a serious burn.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF LONGITUDINAL FRACTURE OF THE TIBIA.

(Under the care of Mr. RICKMAN J GODLEE)

FOR the notes of the case we are indebted to Mr. J. B. Burt, late house surgeon.

A man, aged 46 years, was admitted into University College Hospital on Nov 21st, 1903. Whilst getting off an omnibus he struck his left knee forcibly against the mudguard behind the wheel He was able to stand after the accident but on attempting to walk fell down. On admission to the hospital the injured leg was so painful that any accurate examination was impossible. The leg was swollen and the knee joint was distended; it was evident that there was some severe injury about the joint but its exact nature could not be made out without an anæsthetic.

Under chloroform the physical signs were as follows: 1. Genu valgum—this deformity could be reduced by extension applied to the foot. 2 Undue lateral mobility of the tibia on the femur but no increased antero posterior mobility. 3 An increase of the width of the upper end of the tibia; measured with callipers the greatest width of the upper end of the right tibia equalled three and a half inches and the greatest width on the left side was four inches. Perhaps some slight allowance should be made for the œdema in the latter case. 4 An undue projection outwards of the external tuberosity of the tibia without an equal displacement of the internal tuberosity. 5 No evidence of a transverse solution of continuity of the femur or the tibia. 6. When the upper end of the tibia was compressed laterally a clicking sensation was felt. There was also some coarse, soft grating when the knee was flexed. 7 Distension of the knee joint. Under the anæsthetic the genu valgum was reduced by extension and a Croft's plaster splint was applied. A skiagram showed a longitudinal fissure beginning at the articular surface of the tibia just external to the middle line and extending downwards for two inches On the inner side a small, oblique fracture between the internal tuberosity of the tibia and the shaft could be seen. Ten days after the splint was applied massage and passive movement were employed. The swelling of the leg was still considerable. Ten days later the patient got about on crutches, the injured limb being still fixed in the Croft's splint. When the patient left the hospital the width of the tibia was markedly greater than that of the other side. He could bend the knee through an angle of 30° only. *Attempts at forcible bending of the knee apparently caused* much pain. He attended at the hospital to be seen two months after the accident. Movement was still impaired; he could now move his knee through an angle of 60°.

Remark by Mr. GODLEE.—*The rarity of the accident* and the very imperfect accounts of it which are to be found in the text-books make it worth while to put this case on record, especially as the exact nature of the injury is now ascertainable by means of a skiagram.

LINCOLN COUNTY HOSPITAL.

A CASE OF TOTAL PARAPLEGIA DUE TO CARIES OF THE MIDDLE DORSAL VERTEBRÆ; COSTO TRANSVERSECTOMY; COMPLETE RECOVERY.

(Under the care of Dr. W. H. B. BROOK.)

A YOUTH, aged 17 years, was admitted to the Lincoln County Hospital on Sept. 22nd, 1902, complaining of loss of power in the legs of four weeks' duration. In November, 1901, he noticed a lump on his spine in the mid-dorsal region which was very painful but the pain disappeared after two weeks' rest in bed. He was able to resume work till May, 1902, when he had to give up. He wore a plaster jacket from March to May, 1902, since which time he had been confined to his bed. During the last four weeks he had lost the use of his legs and had had incontinence of urine. There was no family history of phthisis or any form of tuberculosis.

On admission there was an angular curvature of the spine in the mid-dorsal region, the sixth and seventh spinous processes being very prominent. Percussion caused no pain and there were no signs of the pointing of any collection of pus. There was a girdle sensation at the level of the epigastrium Sensation in the legs was much impaired but not entirely lost. The patient could move the legs but not well. The legs were spastic but there was no muscular atrophy. The knee jerks were exaggerated but the Babinski reflex was absent. There was difficulty in retaining the urine which was acid, containing phosphates but no albumin or sugar. The heart and lungs appeared to be healthy. A seven-pound extension was applied to each leg, the foot of the bed being raised, and the patient was ordered compound syrup of phosphate of iron with cod-liver oil and malt. On Nov. 7th, during the six weeks that had elapsed since his admission, the patient had become steadily worse He had now complete paraplegia; sensation was totally lost in the right leg and almost so in the left. The knee-jerks were much exaggerated and ankle clonus was violent Babinski's phenomenon was present in both feet Urine and fæces were passed unconsciously. There was a girdle sensation at the level of the seventh rib but no pain over the prominent spinous processes. In spite of the most careful nursing there were sores on both heels. The temperature was from 98·4° to 98 8° F. A skiagram was taken which showed blurring in the region of the seventh and eighth dorsal vertebræ From this it was considered that tuberculous matter was present and was pressing upon the cord and it was decided to attempt to relieve this pressure by operation

On Nov. 8th, under chloroform, a transverse incision three inches long was made commencing at the right of the sixth dorsal spinous process, slanting slightly downwards and extending to the right. The muscles exposed were cut through until the right transverse process of the eighth vertebra was laid bare; this was cut through at its base and removed. The periosteum of the eighth rib was incised from the head to the tuberosity and carefully stripped from the rib which was divided and its head and neck were removed. Whilst this was being done thick curdy pus welled up and it was found that the head of the rib was carious and detached from the body of the eighth vertebra, which was practically destroyed. A sharp spoon was introduced and all the soft bone was carefully scraped away as far as possible, care being taken not to wound the dura mater or the pleura. A drainage-tube was inserted and iodoform emulsion containing 1 in 40 carbolic acid was injected and the cavity was lightly packed with iodoform gauze. The patient was placed on a mattress made in sections to facilitate dressing and a seven-pound extension was applied to each leg. On the day following there was a slight return of sensation in the right foot and on the third day there was voluntary movement in the great toe of each foot. On the 29th there had been steady improvement from day to day, sensation *was perfect and the legs could be moved freely, but there* was still incontinence of urine and fæces. On Dec. 27th the improvement had continued. He could now lift each leg easily from the bed and there was control over the *bladder and rectum. The sores on the heels* had rapidly healed. The girdle pain had disappeared. On Jan. 8th, 1903, the drainage-tube was discontinued; since the operation the wound had been dressed every other day and the emulsion injected. On the 28th the wound was quite healed. On Feb 4th the patient was fitted with a steel spinal support consisting of a pelvic band and two dorsal rods an inch apart, with shoulder straps and plates so arranged as to support the spine where it was defective. On the 15th he was allowed to sit up for an hour daily, wearing the apparatus. The Babinski phenomenon had disappeared. On March 13th he was able to walk well.

Remarks by Dr. BROOK.—On first seeing the case it was difficult to decide whether the paraplegia was due to compression of the spinal cord or to pachymeningitis, as there was no sign of any collection of pus. The fact that there was no tenderness over the prominent spinous processes excluded meningitis, and the skiagram, which showed a blurring at the site of the disease, was suggestive of the presence of caseous deposit and inclined me to think that I had to deal with a case of pressure paraplegia due to tuberculous matter outside the dura mater. It was suggested that laminectomy might give relief; this, however, would have deprived the spinal column of the support of the only part which at the level of the disease was still sound. I therefore tried what could be done by rest and extension but without any benefit, and I then decided to endeavour to reach the disease from the side. There was no great difficulty about the operation which was rendered all the easier by the head of the rib being detached from the vertebra. Care had to be taken not to damage the spinal cord on the one hand or the pleura on the other. It is interesting to note that although sensation began to return within 24 hours and the ability to move within 48 hours it was not until six weeks had elapsed that power over the bladder and rectum was regained. The disappearance *of the Babinski phenomenon is also of* interest. I have to thank Dr. P. Kinmont and Mr. J. T. Crowe, the house surgeons, for their care and interest in the case and my partner, Dr. A. Stanley Green, for the very excellent skiagrams which he obtained.

BRISTOL ROYAL INFIRMARY.

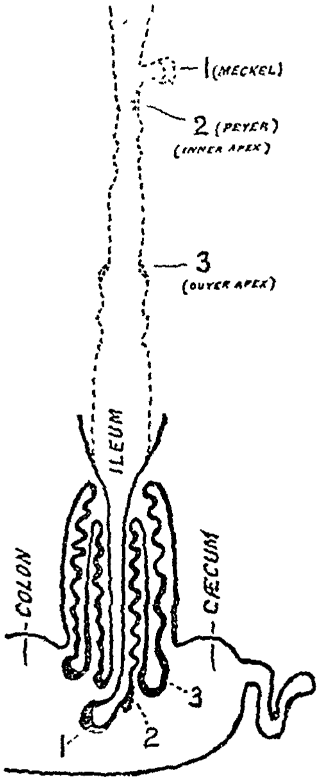
A CASE OF TRIPLE TELESCOPIC INTUSSUSCEPTION ORIGINATING IN MECKEL'S DIVERTICULUM.

(Under the care of Mr T. CARWARDINE.)

A VERY collapsed child, aged 14 months, was admitted under the care of Mr. Carwardine in February, 1903, for intussusception of two days' duration although no tumour could be felt on abdominal examination. A rapid operation was performed and the small gut was eventrated. An intussusception of the lower ileum was found which had just entered the colon. This was reduced with some slight difficulty and then another invagination was found within the first and on reducing the latter an inverted Meckel's diverticulum finally appeared, dark and swollen, and was reduced. There were thus three invaginations, one within the other, like a telescope when closed. The bowel was emptied and nutriment was injected but the child never recovered from the collapse

Necropsy.—At the post-mortem examination a thickened dark Meckel's diverticulum was seen about 15 inches from the ileo-cæcal valve and a gangrenous Peyer's patch half an inch lower down. Still lower was a large patch of early gangrene.

Remarks by MR. CARWARDINE.—As the condition must be extremely rare the illustration may be of service to elucidate



Diagrammatic representation of intussusception.

what may be termed a "telescopic" invagination. The dotted lines represent the parts when reduced and the numerals refer to corresponding points.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on Arterial Sclerosis.

A MEETING of this society was held on Feb. 16th, Dr. F. W. PAVY, Vice-President, being in the chair.

Dr. T. D. SAVILL opened the discussion on Arterial Sclerosis by reading a paper on Arterial Hypermyotrophy and other Morbid Changes which occur in the Muscular Tunic of the Arteries. He said that arterial sclerosis might be defined as a chronic, generalised thickening, condensation, or degeneration of the arterial walls, in which the walls were hard or less elastic than normal and the lumen remained unduly patent after death. Three kinds were recognised—intimal, medial, and adventitial sclerosis—and these should be studied separately. Adventitial and intimal sclerosis were, in Dr. Savill's view, very often secondary to disease of the muscular coat. Atheroma (a patchy fibro-cellular infiltration of the intima) must be regarded as totally distinct from intimal sclerosis. A large number of cases had been examined at the Paddington Infirmary and clinical and pathological details of 30 cases were submitted which presented circulatory symptoms during life and in which the arterial system was carefully studied, with the naked eye and microscopically, after death. The methods adopted were described. Measurements were made with a micrometer eye-piece. The paper dealt almost exclusively with the changes which took place in the muscular tunic. The importance of the muscular coat was first emphasised on histological, physiological, and pathological grounds. The muscular tissue of the arteries constituted the parenchyma or proper tissue of the arterial system, and on its performing its correct function the healthy action of the cardio-vascular and many other systems depended. In relation to the pathological importance of the muscular coat the case of a woman who died at the age of 100 years was described and sections of her arteries and organs were exhibited in illustration of the following conclusions at which Dr. Savill had arrived after examining the bodies of upwards of 400 persons who died at 60 years of age and upwards: (1) that extensive patchy atheroma was consistent with extreme longevity and with the total absence of symptoms or vascular complications; and (2) that the same remark applied to marked generalised intimal and adventitial sclerosis, provided (*a*) that the tunica media was relatively free from hypertrophy or disease and (*b*) that the balance between the heart and arteries was not materially disturbed. On the other hand, moderate disease of the muscular tunic was a serious potential evil. Morbid changes in the muscular tunic of the arteries might be grouped as follows:—1. Atrophy was not common but had been found in some wasting diseases. 2. Hypertrophy was more frequent and was not uncommon after middle life, though the measurements were so refined that it was difficult to be positive. 3 Cloudy swelling in the muscular fibres was a change which could not always be revealed by the stains in ordinary use, but with acid orcein the slightest degree might be demonstrated. Acid orcein was a most valuable stain; by its proclivity for elastic tissue it also defined both the internal and the external boundaries of the tunica media in complex specimens. 4. Granular degeneration was frequently associated with cloudy swelling. All these four changes had a generalised distribution in the arterial system, though often more marked in one area (in the lower extremities, for example) than another. (5) Necrosis and (6) calcification both occurred as spots or foci of various sizes. Calcification might take the form of plates or of transverse spicules. Transformation of the tunica media into fibrous tissue was never met with in specimens adequately prepared and stained. Arterial hypermyotrophy was a term used by Dr. Savill in 1891 and again in 1897 to describe a generalised increased thickness of the muscular tunic of the arteries due to an increased volume, with or without numerical increase, of the individual muscular fibres. It was to be regarded as primarily a genuine muscular hypertrophy, just as an increased thickness in the cardiac wall in like circumstances was so regarded. The fact of degeneration having commenced by the time a case reached the post-mortem room did not negative the existence of hypertrophy. It was very often antecedent to medial degeneration. Clinically arterial hypermyotrophy constituted a distinct pathological condition of prolonged course, capable of recognition during life by careful investigation sometimes but not necessarily associated with chronic renal disease and constituting in itself one of the main pathological conditions on which cerebral and other hæmorrhages depended. The 30 cases which form the chief basis of this communication were divided into two groups. In Group A (17 cases) arterial hypermyotrophy was relatively uncomplicated by other arterial disease and these represented some of the earlier phases of the disorder. Group B (13 cases) were more or less complicated with intimal and adventitial sclerosis and degenerations; these probably represented the final stage. Microscopical sections of the arteries and arterioles were examined, measured, and compared with normal specimens. Typical cases were described. One case was met with while searching for a normal standard. Another was that of a man, aged 56 years, who exhibited numerous circulatory symptoms during life and who died from cerebral hæmorrhage. The urine, kidneys, and other organs were normal, but the heart and arteries presented hypermyotrophy. The average increase of the tunica media amounted to $\frac{5\cdot}{2\cdot5}$ of normal in the lower extremities, $\frac{\cdot1}{2\cdot5}$ of normal in the abdomen and upper extremities, and $\frac{2\cdot6}{2\cdot5}$ of normal in the cerebral arteries. The tunica intima was practically normal. The tunica adventitia was very slightly increased. In the 17 cases in Group A the media measurements showed an average increase in the media amounting to about 50 per cent., the greatest being $\frac{4}{5}$ and the smallest $\frac{1}{8}$. Among the causes of arterial hypermyotrophy, its relationship to chronic renal disease was first discussed. That it resulted from chronic renal disease was admitted. But that it might also occur independently of renal disease was evidenced by the fact that of 30 cases submitted chronic renal disease existed in only four of Group A and in five of Group B; the remaining 21 presented no urinary changes during life or evidence of renal disease after death. Objection was taken to the term "chronic Bright's disease" being applied to a generalised condition, consisting [illegible]

[illegible] suggested that such a generalised condition was in reality a condition described clinically as senile hyperpiesis by Professor Clifford Allbutt, or anatomically as arterial hypermyotrophy, with their concomitant circulatory and nutritional defects. 2. Hypertrophy of the heart existed in all of the 17 cases in Group A and in all but two of the 13 cases in Group B. The average weight of the heart in Group A was 13·9 ounces and in Group B 12·5 ounces. It might be regarded either as a cause or as a result of arterial hypermyotrophy, or as a product of a cause common to both. 3 High blood pressure was observed in all cases of arterial hypermyotrophy seen during life before a final stage supervened. The causes of high arterial tension could generally be revealed in their history and evidently played a leading rôle in the causation of arterial hypermyotrophy. Heredity, age, and other causes were also discussed. The consequences of arterial hyper- [illegible] Among [illegible] occurred [illegible] occurred [illegible] A table of the causes of death was submitted.

Professor **CLIFFORD ALLBUTT**, after alluding to the discussion which had occurred on arterio-sclerosis between Gull and Sutton on the one hand and George Johnson on the other, said that from clinical observation he recognised three forms of arterio sclerosis, which might be superficially alike but were very different in nature and causation. These three forms were: (1) toxic, that was the effect of lead and certain of the infectious diseases, such as syphilis, and of diabetes; (2) involutionary, that was senile decay, a change which might appear before the age of 70 years; and (3) secondary, the effect of arterial hyperpiesis, the form in which the muscular coat of the artery was hypertrophied. The forms 1 and 2 were not necessarily attended by a rise of arterial pressure, but form 3 essentially depended on hyperpiesis for its initiation. The forms 2 and 3 might concur in the same patient, but this was not the rule. In the "involutionary" form calcification was more prone to occur and the disease was more disposed to attack all the coats of an artery than in hyperpiesis. In form 2 the heart was not hypertrophied or dilated, or only in the slighter degrees; it was often in fairly good working order and death did not depend upon strain of the heart. It was on group 3 that the discussion mainly turned and he stated that he was of opinion that the first apparent factor was a rise of arterial pressure and that the arterial disease was a mechanical consequence of the sustained hyperpiesis instead of the converse as was generally believed. This factor probably depended in its turn upon some alteration of the blood and the alteration of the blood again upon some more or less specific perversion of metabolism. The chemistry of the body was perverted, the blood was altered, and whether by this alteration the fluid became more viscous and so traversed its channels more reluctantly or received some quality irritating to the vessels which by their responsive contraction hindered its flow was doubtful. From this abnormal resistance in the periphery the pressure rose, the vessels became dilated, and the dilatation was counteracted by hypertrophy. By this means a balance was brought about and circulation was carried on though with excessive expenditure in labour. He had noticed that even in old people arterial hyperpiesis might establish itself and yet be permanently reduced by appropriate means. The production of the condition depended upon a sedentary life and high feeding, but, on the other hand, it occurred in patients who were perfectly temperate. He believed, however, that replétion, relative or positive, was the cause of the majority of cases. He believed that arterial hyperpiesis had a definite train of symptoms and formed a distinct clinical type.

Dr. J. F. H. **BROADBENT** held that under the term "arterio-sclerosis" must be included degenerative lesions of the aorta comprised under "atheroma," as well as those of the smaller vessels. It was scarcely possible to consider them apart as the two conditions were etiologically and pathologically closely allied. In studying a case of vascular degeneration it was advisable to examine carefully macroscopically and microscopically the condition of the aorta, cerebral vessels, kidney, coronary arteries of the heart, and one of the vessels of the extremities—e g., the radial—as the incidence of the lesion varied greatly. On these lines he had examined the vascular changes in some 16 cases of cerebral hæmorrhage, which was one of the most common accidents associated with arterio-sclerosis. In two instances the patients were 80 years of age and the hæmorrhage was the result of senile degeneration of the vessels. Of the remaining 14 seven were associated with granular kidney, and seven with a *type of kidney in which the most* characteristic changes were thickening and hyaline degeneration of the inner coat of the vessels; the kidneys were of about normal size, the capsule stripped leaving a smooth surface, and the [illegible] In all these 14 [illegible] artery were greatly hypertrophied but the latter showed no signs of degeneration. The cerebral vessels were dilated, thin, and hyaline, or were studded with small white patches which microscopical examination showed to consist of localised thickening and degeneration of the sub endothelial tissue over which the muscular coat could be traced, though thin and atrophied in some instances. In four cases there was advanced atheroma of the aorta; in the remainder there were only slight degenerative changes immediately above the aortic valves or no appreciable naked-eye change. The condition of the coronary arteries was not investigated in all the cases, but in two there was advanced degeneration and in four they appeared healthy. The main clinical characteristics [illegible] admission, so that the clinical history was imperfect The high tension was presumably due to increased peripheral resistance from a tonic contraction of the arterioles and capillaries induced by some toxic substance in the circulation. In granular kidney the toxin was the result of imperfect elimination by the diseased organ In the second group of cases high arterial tension probably antedated by many years disease of the kidney and the toxins which induced hypertonicity of the peripheral arterioles also gave rise to the thi[illegible] the renal vessels. They [illegible] e g., lead—or they migh[illegible] due to imperfect metab[illegible] and a gouty diathesis were important factors. The increased peripheral resistance induced hypertrophy of the heart and muscular coat of the systemic arteries which was not to be regarded as a disease but as a response to increased work. The cerebral vessels, however, being poorly provided with muscular tissue became dilated *under the constant and increasing* pressure; their nutrition was interfered with, thickening and degenerative changes occurred in the sub endothelial tissue, the muscular coat became atrophied over the bulging necrotic tissue, and rupture frequently occurred. This type of degeneration, common in the aorta and cerebral vessels, was not met wit[illegible] degeneratio[illegible] ration of t[illegible] From the [illegible] induced by some prolonged toxæmia and to which hyaline degeneration was akin he thought it probable that toxic products in the circulation were the predominant factors in vascular degenerations in the kidney, while high arterial tension was mainly responsible for lesions in the cerebral vessels. In regard to degenerative changes in the aorta with which aneurysm was so frequently associated, intermittent strain associated with arduous occupations was doubtless in many instances responsible, as Professor Clifford Allbutt had originally suggested. Syphilis was, however, an important etiological factor in a large number of cases. Clinically, from the history of the case, the age and occupation of the patient, the condition of the vessels, and the presence or absence of high arterial tension, it was possible in the majority of cases to arrive at a diagnosis as to the cause of the degenerations. Post mortem it was not easy from a macroscopical examination to form any certain conclusion. Microscopically in a certain number of cases he had found endarteritis obliterans of the vasa vasorum which had caused localised areas of necrosis in the vessel wall from impaired nutrition. In two of these cases there was a definite history of syphilis and he thought that by careful microscopical examination a differential diagnosis between degenerative lesions due to syphilis and those due to strain or other causes might be made on these grounds. Dr. F. W. Mott, in his article in Allbutt's "System of Medicine," had called attention to endarteritis obliterans of the vasa vasorum in syphilis. Possibly other toxins might act in this way; it was common to find patches of degeneration in the aorta of young children who had died from an acute illness such as pneumonia or septicæmia, or from tuberculosis or diabetes, and he thought that in many instances such localised degenerations might be the origin of degenerative lesions leading to aneurysm in later life.

Dr. F. PARKES WEBER observed that admitting the justness of Dr. Savill's contention that the unstriped muscle ought to be considered the parenchymatous tissue of the arterial walls in the same sense that cardiac muscle was termed the parenchymatous tissue of the heart walls, he (Dr. Weber) thought it followed that arterial hypermyotrophy bore the same relation to arterio-sclerosis that cardiac hypermyotrophy bore to cardio-sclerosis. The discussion that evening had centred rather on arterial hypermyotrophy than on arterio-sclerosis. Dr. Weber thought that in most cases the hypertrophy in the muscular part of the arterial walls served a useful (that was a compensatory) purpose and illustrated the laws of action and reaction which governed vital phenomena in general Apparent exceptions were, however, to be found in cardiac or arterial hypermyotrophy of nervous origin, such as the cardiac hypermyotrophy sometimes met with in persistent tachycardia without valvular disease (some cases of Graves's disease) and the arterial hypermyotrophy sometimes met with in limbs affected by conditions allied to erythromelalgia and Raynaud's symptom-complex. These apparent exceptions to the general rule of vital reaction doubtless arose from portions of the nervous system (concerned in the reactions in question) themselves being abnormal. As a possible, though very rare, cause of arterial hypermyotrophy Dr. Weber instanced a condition on which Professor Osler and others had recently written, in which the blood was about twice as rich as it normally ought to be in red corpuscles. Such an extreme increase in the proportion of corpuscles must necessarily render the passage of the blood through the arterioles more difficult

Dr. PAVY said that the two important factors in the production of arterio-sclerosis were some toxic agent and renal disease. Cases did, however, occur which in their superficial aspect presented all the characters of Bright's disease, but on examination of the urine there was no albumin or cast. He mentioned the case of a woman who at first suffered from attacks of headache, vomiting, and transient aphasia from which she rapidly recovered. At this time the urine contained no albumin and no casts. Some years later the attacks of headache recurred and the arterial tension became greater, and at a later period granular casts appeared in the urine and at a still later time albumin. The cardio-vascular symptoms preceded the renal disease. It was probable that a defective metabolism gave rise to a toxic agent which produced the vascular change. He mentioned a case in illustration of the fact and said that it was of great importance to diminish the quantity of nitrogenous food in such cases.

CLINICAL SOCIETY OF LONDON.

Fibroid and Calculous Disease of the Pancreas with Jaundice and Diabetes.—Two Cases of Malignant Anæmia associated with Caries of the Teeth and Suppuration of the Upper Jaw.—Operation for Ankylosis of the Temporo-maxillary Joint —Two Cases of Tuberculous Disease of the Thyroid.

A MEETING of this society was held on Feb. 12th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. SIDNEY P PHILLIPS reported a case of Fibroid Disease and Calculi of the Pancreas with Jaundice and Diabetes. The patient was a married woman aged 26 years, who about Christmas time, 1901, began to suffer with epigastric pain. In February, 1902, jaundice appeared with absence of bile from the stools. There was no history of biliary colic. An exploratory operation was performed t St. Mary's Hospital by Mr. Edmund Owen[1] on April 3rd, when a great enlargement, judged to be non-cancerous. of the pancreas was found. On June 14th 8 per cent of sugar was present in the urine and six months later the jaundice entirely disappeared but the diabetic symptoms progressed. On Jan. 25th, 1903, she was attended at her home by a medical man for diabetic coma from which she died on the following day. A partial necropsy was obtained. The pancreas was much enlarged and presented a considerable degree of fibroid change throughout, with numerous small calculi of varying size, so that sections of the organ were gritty. Microscopically there were almost complete replacement of pancreatic tissue by fibrosis and destruction of the islands of Langerhans. The occurrence of the jaundice was explained by obstruction of the common opening into the duodenum of the pancreatic and bile ducts. The glycosuria was of the type usual in pancreatic diabetes. The diagnosis of pancreatic disease in this case was not assisted by the administration of salol.—Dr. NORMAN DALTON inquired whether the pancreas was smaller at the necropsy than at the time of operation and pointed out that its diminution in size was probably analogous to that of a cirrhotic liver.—Mr. LEONARD A BIDWELL remarked that the gall-bladder was generally distended in cases of chronic pancreatitis. He thought that the gall-bladder should have been explored in this case He had operated upon four cases of this affection and in none of them was glycosuria observed after the operation. The cause of the jaundice in the present case might have been due to a calculus which had been originally impacted in the ampulla of Vater —Dr. WILLIAM PASTEUR remarked on the view that was held that obstruction of the pancreatic duct led to fibrosis of the pancreas and referred to a case in illustration of occlusion of the pancreatic duct by scar tissue in the duct. All the ducts in the pancreas itself were dilated but there was no fibrosis in this instance.—Dr. PHILLIPS replied.

Dr. DALTON narrated two cases of Malignant Anæmia associated with Caries of the Teeth and Suppuration of the Upper Jaw. The first case was that of a man, aged 21 years, suffering from debility, pallor, anæmic bruits, epistaxis and other hæmorrhages, and vomiting. The disease lasted only eight months and there was no necropsy. There was no enlargement of the spleen or lymphatic glands. The interest centred in the urine, the suppurative lesions, and the blood. The urine was never high-coloured. The teeth were carious and there was an alveolar abscess which after incision left a sinus in the hard palate. Otorrhœa was also present. The blood showed progressive oligocythæmia, the red discs falling from 1,200,000 per cubic millimetre on admission to 393,720 three months later. The hæmoglobin was also diminished and there was marked leucopenia, the lymphocytes being in excess of the polynuclear cells. The second case was that of a girl, aged 17 years, who had lived in extreme poverty. She had been ailing for some time but the illness only became acute three weeks before she was admitted to King's College Hospital, where she died five days later. The urine was pale, the teeth were carious, and there was an abscess in the upper jaw from which pus was constantly oozing. The blood only contained 816,000 red cells per cubic millimetre and 17 per cent. of hæmoglobin. The leucocytes numbered 3500 per cubic millimetre. At the necropsy there were subserous and submucous hæmorrhages. There was no free iron in the liver and the red marrow was fatty. In neither case could surgical treatment be undertaken on account of the tendency to hæmorrhage. Dr. Pasteur had described an exactly similar case but there was no suppurative lesion —Dr. WILLIAM HUNTER agreed that the cases corresponded in a remarkable way to those which he had described as "septic anæmia" which had been previously included under the title of "pernicious anæmia" but were distinguished therefrom by the absence of evidence of the hæmolytic changes in the urine, the presence of a low type of pyrexia, the absence of the bone marrow changes generally seen in true Addisonian anæmia, and the grave prognosis attached thereto unless the focus of suppuration could be removed.—Dr. PASTEUR referred to the case which he had brought before the society last November in which hæmolysis was excessive but there was no suppurative lesion. He therefore concluded that for the present his case must stand alone.—Mr LEONARD S DUDGEON inquired if streptococci were present in the blood previously to the injection of antistreptococcic serum.—Dr F PARKES WEBER understood Dr. Dalton to say that something more was necessary for the production of anæmia than sepsis alone.—Dr DALTON replied that he considered that persons with carious teeth were always in danger because at any moment an unknown factor might supervene and convert a condition of simple ill-health into a malignant form of anæmia which was rapidly fatal. He thought that Dr. Hunter's phrase of "septic anæmia" was a little unfortunate as tending to cause some confusion with the true Addisonian anæmia in which a special form of sepsis occurred on the tongue.

---

[1] Brit. Med. Jour., Oct. 25th, 1902.

Mr. J. JACKSON CLARKE described a case of Excision of the Neck of the Lower Jaw for Temporo-maxillary Ankylosis. The patient was a woman, aged 35 years, on whom four years ago he had performed this operation on both sides for ankylosis following a general infective arthritis, probably gonorrhœal in origin. She could now separate the edges of the incisor teeth three quarters of an inch and could masticate with comfort.—Mr. T. H. OPENSHAW referred to cases of his own in which he had resected both condyles with good results.

Mr. OPENSHAW exhibited three cases of Fracture of the Bones of the Leg treated by immobilisation in Hoefftcke's apparatus and a modified Hessing's splint case appliance.

Mr. EDRED M. CORNER read notes of two cases of Primary and Secondary Tuberculosis of the Thyroid Gland. In the first case, that of a girl, aged nine years, the condition was found during life, an abscess in the right lobe and a sinus leading to a diseased left lobe being present. The wounds refused to heal until thyroid extract was administered. The child died seven months later from general tuberculosis. The second case was discovered post mortem as a caseous mass in the right lobe of the thyroid in a woman who had died from pulmonary thrombosis and phthisis. The condition was really a clinical curiosity, as localised tuberculous deposits in the gland were extremely rare.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Functional Albuminuria.

A MEETING of this society was held on Feb. 5th, Dr SEYMOUR TAYLOR the President, being in the chair.

Dr. SAMUEL WEST read a paper on Some Points in Functional Albuminuria. Discussing the various names by which the condition had been described, he expressed preference for that of albuminuria in the apparently healthy because it represented the facts that albumin was present in the urine and that the albuminuric patient was in other respects apparently healthy. This name also suggested the practical difficulty which arose in every case—viz., the difficulty of being certain that the person was actually and not only apparently healthy. Although by delicate and repeated tests the presence of albumin might be demonstrated in the urine of practically everyone, when shown by ordinary clinical methods of examination albuminuria could never be regarded as physiological but always as evidence of some abnormal or pathological condition. Functional or physiological albuminuria might therefore be described as albuminuria for which the cause was not obvious. The diagnosis was arrived at by the method of exclusion and it was impossible to be certain that all the possible causes had been eliminated. Many of the known facts about functional albuminuria were sufficiently indicated by the various names given to it, such as occasional, intermittent, remittent, cyclical, postural dietetic, and the like The importance and significance of albuminuria varied with the age. It occurred frequently in infants and young children, in which cases it was generally of little significance, though further observation was much needed on this point. The largest number of observations was concerned with the next age group—viz., that of boys at school, in whom the average frequency seemed to be about 20 per cent. The boys forming this group fell into two classes—the one full-blooded, florid vigorous lads with good or even high pulse tension, the other pale flabby, ill conditioned, and with low pulse tension These groups probably presented differences in pathology and prognosis and demanded different treatment. In many the albuminuria completely disappeared, in others it persisted for many years without apparent loss of health, while in a few ill-health and evidence of kidney disease supervened. In young adults with albuminuria further important questions arose in connexion with life assurance and appointments in public offices or business houses. It was at present impossible to determine in any given case whether the albuminuria was transient or likely to persist with evidence of kidney lesion. If differentiation were ever possible it would be largely due to the work of the family medical adviser who had special opportunities for observation in such cases. After 30 years of age the frequency of albuminuria increased with every year of life, together with an almost *pari passu* rise in the gravity of the condition. In granular kidney all the features of functional albuminuria might be produced, but in all well marked cases other signs of the kidney lesion would be found, chief among these being arterial thickening. If in any given case there was general arterio-sclerosis the conclusion was justified that, whatever the cause of disease might be, the patient was not really healthy and could not be suffering from physiological albuminuria. The general conclusion was that albuminuria was never truly physiological at all, but always pathological, though not necessarily renal.

The PRESIDENT considered all such cases, provided that catheter specimens of the urine contained albumin, to be pathological, but urged the necessity for careful microscopical examination to supplement this evidence. The presence of tube casts, free blood, or an excess of desquamated renal epithelium rendered the diagnosis of renal disease imperative. If signs of increased tension in the renal pulse, accentuation of the aortic second sound, and displacement downwards and outwards of the heart's apex beat were present, although the albuminuria might be fugitive, all such cases must be regarded as coming under the category of Bright's disease.

Dr. G A SUTHERLAND believed the postural or orthostatic variety to be a definite form of functional albuminuria. In these cases albumin appeared in the urine soon after the patient assumed the erect position in the morning and decreased in amount as the day went on The patients were most frequently young adolescents who exhibited accompanying symptoms which were very definite, chiefly of the nature of general vaso-motor disturbance and which might be best summed up under the term "neurasthenia." There were none of the signs or symptoms of nephritic diseases in these cases. All the classical symptoms of adult neurasthenia were reproduced in these cases and he had found from experience that treatment of this underlying condition was productive of the best results.

Dr E A SAUNDERS agreed with the President as to the necessity for microscopical examination of the urine in every case. The presence of a few hyaline casts he did not consider of greater clinical significance than the occurrence of albumin itself, but if many casts were present, especially if these were of the granular variety, they might be taken as evidence of chronic kidney disease. In estimating the prognosis in cases of albuminuria in the apparently healthy he attached great importance to the age of the patient and the amount of the albumin. After 30 years of age the gravity of the condition increased with every year of life and, speaking generally, the larger the amount of albumin present the more serious the prognosis became.

HARVEIAN SOCIETY OF LONDON.—A meeting was held on Feb. 11th Dr C Theodore Williams, President, being in the chair.—Mr. Edmund Owen read a paper on Appendix Abscess in the Recto-Vesical Pouch He advocated treatment by abdominal section in preference to drainage by the rectum or vagina, as by the latter method he feared fistula would be a very probable sequela and the duration of recovery would be tedious Mention was made of vesical symptoms—frequency of [illegible] the course of a case whic [illegible] Owen preferred drainage [illegible] arnard said that Mr Owen's objections to drainage of pelvic appendix abscess by the rectum or the vagina were theoretical In more than ten cases so drained Mr. Barnard could state that none of those ill-effects which Mr Owen referred to had followed The drainage of pyosalpinx through the vagina was not a true analogy, as experience also proved. Indeed, Mr. Barnard still maintained that when an abscess was strictly localised in the pelvis it should be opened by the rectum or the vagina. The surgeon could tell that it was so restricted by feeling a tense round mass covered by the œdematous mucous membrane of the anterior rectal wall together with absence of fulness or tenderness in the iliac fossa.—Mr. G Lenthal Cheatle stated that he had seen three cases of abscess in connexion with appendicitis in which the pus had extended to the upper part of the recto-vesical pouch and had given rise to pain with frequency and difficulty of micturition. In another case in which there was too much abdominal distension to feel anything in the right iliac fossa, but the patient had vesical symptoms, he diagnosed a similar condition, and he now looked upon this set of symptoms as indicating immediate operation in cases of spread towards the recto-vesical pouch. He had only once felt the swelling per rectum and then the abscess was very large He considered abdominal section the better treatment.—Mr. W. McAdam Eccles said he was accustomed to make a distinction in the question of treatment of localised pelvic abscess in the two sexes. In males he attacked them suprapubically; in females he cleared up the diagnosis by median incision, dealt with the affected organ, and drained per vaginam, frequently closing the anterior abdominal wound.—Mr W. Spencer believed the best time to remove an appendix was in the first 24 hours and advocated drainage by gauze in preference to tubes; he considered it wise always to remove the appendix in cases of suppuration as relapse or trouble frequently followed its omission He hoped drainage by the rectum or vagina would not be followed.—Mr. F. Jaffrey entirely concurred with Mr. Owen as to the inadvisability of draining by the rectum or vagina.—Mr. Owen replied.—Mr. E. W. Roughton read a paper on a case of Intestinal Obstruction with Gangrene of the Cæcum. An umbilical hernia existed but was soft, painless, and gave an impulse; it was therefore not the source of the symptoms. A median incision was made and an enormously distended cæcum was seen. During manipulation the cæcum burst and flooded the operation area with fæces, but the peritoneum was protected by gauze packing and a Paul's tube was tied in. Later Mr. Legg removed a cancerous growth from the sigmoid flexure, the portion removed including four inches of the gut and a wedge of the mesentery. End-to-end suture was employed, the first layer through all the coats and the second through the seromuscular coats, and the parietal wound was closed. The colotomy wound was plugged with a sponge and the skin was sutured closely over it during the operation. The patient did well.—Mr. E. P. Paton discussed two cases of partial hernia which he had recently treated, in one of which, although a small portion of the gut was tightly constricted and was sloughing through, the symptoms were purely local; in another case the hernia was associated with local symptoms which rather resembled those of perforated gastric ulcer, thus showing how sloughing of the gut often gave rise to anomalous symptoms.—Mr. Roughton replied.

Dermatological Society of London.—A meeting of this society was held on Feb. 10th, Mr. Malcolm A. Morris being in the chair.—Dr. S. E. Dore showed: 1. A woman, aged 30 years, who had suffered from an Annular and Gyrate Erythematous Eruption coming out in the winter and lasting for about six months for the last seven years. The eruption when shown consisted of some small patches of about the size of a sixpence and larger rings with hard œdematous edges. The history was that the individual lesions had been present for about three months. 2. A man, aged 65 years, with a Symmetrical Curtain-like Eruption affecting the face and chin and similar patches on the extensor surfaces of the elbows and scalp. The eruption consisted of a very superficial infiltration of the skin with granulomatous tissue and was generally considered to be an unusual case of lupus vulgaris.—Dr. H. G. Adamson showed a little girl, aged seven years, in whom had appeared seven patches of Disseminated Lupus scattered over the face, trunk, and extremities. The eruption occurred after an attack of measles.—Dr. T. Colcott Fox showed a man, aged 30 years, suffering from a crop of Scattered Papules over the Face. The lesions had been present for four months and individually resembled lupus nodules. He believed them to be instances of the acneiform tuberculide.—Dr. E. G. Graham Little showed: 1. A case of Lupus, which had been treated without very great success by means of the light treatment and had since undergone a course of the tuberculin R. The disease showed a very marked improvement as the result, many of the nodules having quite disappeared. 2. A case of Obstinate Sycosis of several years' duration which had been treated with antistaphylococcic injections by means of Wright's method. Although the case had only had four injections the result was already a great improvement.—Dr. W. T. Freeman showed a man, aged 42 years, who had had some large Infiltrated Patches on the Scrotum for fifteen years and many Large Papules distributed over the forehead, cheeks, chin, and scalp for five years. The nodules were as large as peas and extremely like syphilis in appearance but the peculiar history threw doubt upon this. The case was shown for diagnosis and no very decided opinion was expressed.—Mr. Willmott H. Evans showed a case of Thickening of all the Tissues round the Eyes and Forehead in a man who had been in South Africa. The condition had been progressively extending for two years and he thought it was due to chronic streptococcic infection.—Dr. H. Radcliffe Crocker showed a case of Multiple Lupus Vulgaris in which the lesions had all come out in a week ten years ago and had since progressed to form large patches.—Dr. A. Whitfield showed a case of Herpes Gestationis of two months' duration in a woman who was three months pregnant for the first time.

Royal Medical Society of Edinburgh.—A meeting of this society was held on Feb. 5th, Dr. H. D. Shepherd being in the chair.—Dr. D. M. Callender described the case of a soldier who had died in hospital a few hours after a Fall from a Height of about 50 feet. During life the bony lesions discoverable were a compound fracture of the lower jaw and a dislocation of the os magnum of the left carpus. The patient suffered from hæmaturia but no fracture of the pelvic girdle could be made out. A Sprengel pump was used and at first only drew off blood but later clear urine was drawn off. At the post-mortem examination, from which Dr. Callender showed specimens, a fracture of the horizontal ramus of the left pubic bone was found. This had given rise to a rupture of the bladder.—Dr. L. C. Peel Ritchie read a paper on the Bioskowski Joseph Bacillus of Syphilis. The bacillus, of which specimens were shown under the microscope, was cultivated on placental tissue. Dr. Ritchie described its characters and the appearances presented by cultures on various media.—A dissertation on the Relation of the Thyroid Gland to Connective Tissue by Dr. C. J. Shaw was read in his absence by Dr. T. B. Hamilton. Dr. Shaw described the conditions found in cretinism, myxœdema, exophthalmic goitre, and after excision of the thyroid, and discussed the theory of Dr. D. Berry Hart that improper development of the thyroid in the fœtus was the cause of hydatid mole.——A meeting of the society was held on Feb. 12th, Dr. Shepherd being in the chair.—Dr. C. M. Campbell read notes of a case of Paralysis Agitans in a patient aged 35 years. The mask-like character of the face was pronounced. A peculiarity of the case was that the symptoms still remained unilateral, although the condition had been present for over three years. Dr. Campbell also described the case of a girl, aged 18 years, who had had a series of fits culminating in left-sided hemiplegia. Optic neuritis was also present. Under the diagnosis of cerebral tumour craniotomy was performed. No tumour was found but the operation relieved intracranial tension and the patient's symptoms improved. There was a large hernia cerebri through the opening made in the skull and from this a leakage of cerebro spinal fluid went on for several months. Any attempt to reduce the protrusion caused a recurrence of the patient's symptoms. Lumbar puncture had been tried on three occasions. This caused considerable diminution in the protruding mass but the improvement was only temporary.—Dr. Macrae Aitken read a dissertation on the Treatment of Spastic Paralysis of Infants. If the paralysed muscles were stretched, the limb put up in splints in the relaxed condition, and treated by massage for three months considerable power of movement might be recovered. The muscles must then be educated to perform various movements. Operative interference by tenotomy or tendon transplantation was often of value.—Dr. W. C. Morton read notes of cases of Sarcoma of the Femur and Appendicitis.

Laryngological Society of London.—A meeting of this society was held on Feb. 5th, Mr. Charters J. Symonds, Vice-President, being in the chair.—Dr. E. S Yonge showed Professor Meyer's Apparatus for demonstrating the Laryngeal Image and Intra-laryngeal Manipulations. The apparatus was examined by most of the members of the society and proved to be extremely suitable for the purposes mentioned.—Dr. Yonge also showed Microscopical Sections of Bone and Soft Tissues from a case of early polypus. The sections showed that the subjacent bone was perfectly healthy and that there were no signs of either caries or necrosis.—Dr. H. L. Lack showed: (1) A case of Malignant Disease of the Tonsils in which he had operated with good results; (2) a Microscopical Section of Endothelial Maxillary Antrum; (3) a Microscopical Section and patient showing Endothelial Larynx; and (4) a specimen of Large Osteoma of the Ethmoid with Nasal Polypi.—Dr. E. F. Potter showed a case of Recurrent Papilloma of the Larynx.—Dr. A. Thorne showed: (1) A case of Immobile Left Vocal Cord in a man, aged 35 years; (2) a man, aged 35 years, with Severe Paroxysmal Pain starting in the Larynx; and (3) a Tumour of the Right Side of the Larynx in a woman, aged 45 years. This latter case gave rise to a fair amount of discussion, the general opinion of the society being that the tumour was of tuberculous origin.—Mr. H. W. Carson showed a case of Laryngeal Ulceration in a phthisical patient for diagnosis.—Mr. R Lake exhibited a case of Subglottic Thickening.—Dr. J. Donelan showed a youth with [illegible] improved by opera- [illegible] showed: 1. A case [illegible] pain in swallowing in a female patient, aged 45 years. The question was whether it was tuberculous perichondritis. 2. A case of Chronic Œdema of the Larynx which had been shown before to the society in a middle aged female, probably tertiary specific infiltration, and greatly improved under mercurial inunction. 3. A case of Ulceration of the Pharynx af[illegible] the larynx [illegible] in a middle [illegible] from a man, aged 48 years, showing a Pin which had been in the larynx for four and a half years and which had been removed subsequently by lateral laryngotomy.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Feb. 10th at Bolingbroke Hospital, Mr. E. F. White, the President, being in the chair.—Sir Felix Semon addressed the meeting on Some Desultory Remarks on Topics of Professional Interest. He reviewed the course of medical education as conducted in this country and contrasted it with conditions existing in Germany. He observed that in educational matters generally the Germans were more thorough and more in earnest. The German boy worked from morning to night from about the age of eight years till he was 19 years of age, but it was at the expense of his individuality. The love of sport largely contributed to make the English boy what he was, but it would take some generations to infuse this into the German boy. In the medical curriculum Sir Felix Semon strongly advocated that there should be more time allotted to clinical education. There was in this country too little time spent in clinical work as compared with theoretical subjects. He suggested doing away with the theoretical departments attached to each London hospital and substituting one an[illegible] ment for the whole of Lon[illegible] advantages in possessing [illegible] Every student should po[illegible] methods of precision, such as the use of the ophthalmoscope, laryngoscope, rhinoscope, and bacteriology. Sir Felix Semon criticised the manner in which medical examinations were conducted in England. He considered the tests insufficient —there was too large an element of chance by which the best [illegible] a number of portals to the medical profession as existed in England. All men should be put on the same footing and every [illegible] the maintenance of h[illegible] opinion that the day [illegible] to be put on the rates. He concluded his remarks by some observations on the relation of the consultant to the general practitioner.—After the address an animated discussion took place, much diversity of opinion being expressed upon the subjects brought forward.—The meeting closed with a hearty vote of thanks to Sir Felix Semon.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Kent Dispensary, Greenwich, on Feb. 5th, Dr. R E Scholefield, the President, being in the chair.—Mr. Charles Ryall read a paper on the Surgical Treatment of Appendicitis. He first drew attention to the necessity of anatomical knowledge of the part and also of the pathological changes that do, or are likely to, take place. Attaching too much importance to tenderness at McBurney's point sometimes led to errors of diagnosis, as frequently the appendix was both unduly long and moveable, and therefore the site of tenderness depended on the position of the organ at the time of the attack. Death was usually caused by too late an operation and therefore it was of primary importance to watch carefully for any signs of complications and not to wait until diffuse peritonitis had a chance of developing. In fact, it was better to operate when in doubt than to delay until more definite symptoms of complications had developed. Most cases rapidly improved eight hours after the onset and any failure of this to take place usually indicated some complication necessitating operation. The pulse was the chief sign by which to be guided and should this remain high or show signs of increasing it was to be regarded as a danger signal. Recurrence or persistence of vomiting, increase of pain, or tenderness and extension of abdominal rigidity all called for operation Prolonged tenderness after subsidence of attack denoted imperfect recovery and such cases should be operated on. Many cases operated on in the quiescent period and even at a considerable time after the attack revealed the presence of such lesions as kinking, stricture, ulcerations, or concretions, and yet these lesions might not cause any tenderness or give evidence of their presence, although at the same time they were a grave source of danger. They had no means of detecting the presence of these lesions or how long many of them might persist, and therefore he considered the only way to insure the future safety of patients was to have the appendix removed after a first attack and this he maintained was the proper treatment.—The President, Dr. J. H. Bryant, Mr. J. P. Purvis, and Dr. J. H. Keay discussed the paper and a vote of thanks was passed to Mr. Ryall.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in University College, Dundee, on Feb. 5th, Dr. A. J. Duncan being in the chair.—Before the ordinary business was proceeded with sympathetic reference was made from the chair to the death since the last meeting of a former president, Dr. Samuel Lawrence of Montrose.—Professor J. A. C. Kynoch showed a mother and her child after Cæsarean Section and read notes on the case. The operation was performed before the onset of labour for pelvic contraction. The pelvis was of the small flat rickety type; its conjugate was estimated to be about three inches. The patient was sterilised by ligature and division of the Fallopian tubes. Beyond a rise of temperature to 101° F. on the second day the convalescence was absolutely satisfactory. The child was put to the breast on the sixth day and nursing was continued throughout the period of convalescence.—Mr. D. M. Greig read a paper on the Surgical Treatment of Empyema, giving the results of 84 consecutive cases of his own, 21 of which ended fatally and the remainder successfully. The operation performed must aim at safety, evacuation of the empyema, and the early closing of the cavity. The technique of the operation which he was accustomed to perform was given and in this connexion he emphasised the importance of getting rid of the fibrinous exudation at the operation. It was immaterial whether the incision was in the anterior, middle, or post-axillary line if sufficient room was obtained for evacuation of the fluid and removal of the amount of ribs required. If it were in the posterior line the difficulty arose that the patient had to be raised slightly. He usually adopted the incision in the mid-axillary line. The fluid ought to be examined microscopically, as pneumoco[illegible] healed more quickly than the [illegible] tion alone. He would operat[illegible] the physicians desired it but [illegible] He had not found any danger [illegible] fluid.—Mr. George H[illegible] operation in adults [illegible] the same extent in [illegible] of portions of two rib[illegible] was necessary for free drainage. In his opinion the drainage tube was then quite useful.—*Professor* A. M. Stalker and Dr. J. S. Y. Rogers also took part in the discussion.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Dr. A. E. Maylard, the President, being in the chair.—Dr. J. M. Munro Kerr showed a Uterus which he had removed on account of malignant disease complicating a pregnancy of about eight months. The tumour was excised per vaginam in order to avoid the possibility of septic infection of the peritoneum; the uterine arteries were secured; Cæsarean section was then performed, delivering a living child; and [illegible] the whole uterus was extirpated through the abdominal wound.—Mr. J. Grant Andrew showed a large Single Hydronephrotic Kidney which during life gave rise to symptoms simulating those of appendicitis. The illness started somewhat suddenly with pain in the right iliac region and constipation. Fulness and tenderness in that region and the occurrence of rigor suggested abscess. At the operation, after about three weeks, it was discovered that the swelling was a hydronephrotic kidney the contents of which were somewhat purulent; it was simply drained. Acute suppression of urine followed and the patient died two days later. At the necropsy it was found that there was only one kidney which was of a large size and of a shape suggesting fusion of the two kidneys. The patient had contracted gonorrhœa a week before the onset of the illness; this was regarded as the source of infection which converted a hydronephrosis, which had previously given rise to no symptoms, into a pyonephrosis which simulated an abscess of the appendix vermiformis. Gonococci were not found in the contents of the kidney.—Dr. John Anderson showed specimens of the Prostate Gland extirpated by Mr. R. H. Parry in accordance with Freyer's method. In three specimens which were entire a portion of the membranous urethra was present and quite out to the surface of the removed masses prostatic tissue could be recognised.—Dr. Napier showed a patient suffering from Cerebral Tubercle who improved greatly after treatment by repeated lumbar puncture; he also read notes of other cases treated in a similar way.

LIVERPOOL MEDICAL INSTITUTION.—A pathological meeting of this society was held on Feb. 11th, Dr. James Barr, the President, being in the chair.—Dr. K. A. Grossmann exhibited a Congenital Subconjunctival Lipoma removed from a child, aged eight months.—Mr. W. Thelwall Thomas showed a Squamous-cell Carcinoma of the Gall-bladder and commented on its great rarity.—Dr. Nathan Raw exhibited the Kidneys of two cases showing Cystin Calculi *in situ*.—Dr. W. Carter exhibited microscopical specimens of the Crystals of Cystine.—Specimens were also shown by Dr. Hubert Armstrong.—Sir William M. Banks exhibited a Pigmented Carcinoma of the Vagina, secondary to a mammary growth removed ten years previously.—Mr. Keith W. Monsarrat read a note on the Definition of the Term "Carcinoma" in which he briefly traced the sense in which the word had been used from the earliest times and endeavoured to give a precise meaning to the word as now used.—Dr A. S. F. Grünbaum read a note on the Germinal Theory of Cancer in which he alluded to recent work on this subject. Some excellent photographs were shown of karyokinetic division.—Dr. Grünbaum also exhibited a series of microscopical preparations illustrating New Growths in Animals.—Mr. E. M. Stockdale, Mr. Thomas, Mr. Monsarrat, Sir William Banks, Dr. Buchanan, and Dr. Wigglesworth joined in the discussion.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 10th, Dr. E. S Reynolds, the President, being in the chair.—Mr. A. J. Rodocanachi mentioned a case of death from Thyroid Intoxication after Removal of a Goitre and showed the specimen.—Dr. Archibald Donald made a communication on the Pathology of so-called "Idiopathic Endometritis"—In the absence of Dr. Julius Dreschfeld Dr. Charles H. Melland gave an account of a case of Leucocythæmia which showed several unusual features. The case was one of the splenomedullary type and the character of the blood as well as the patient's general condition was profoundly modified by active treatment with large doses of arsenic. On one occasion within three weeks the number of leucocytes fell from 253 000 in the cubic millimetre to 16,000, and a month later, after 15 minims of liquor arsenicalis had been taken three times a day for three weeks, the leucocyte count actually fell to 800 in the cubic millimetre, and at the same time the patient's general health was better than it had been for years. At a later stage he developed tuberculosis. Specimens of the blood at various stages and sections of the various organs affected with tubercle were exhibited as card specimens.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 10th, Mr. J. Paul Bush being in the chair.—Dr. H. Waldo showed a recent specimen of a Lung from a boy who had died from hæmoptysis, a caseating gland having ulcerated into both œsophagus and trachea.—Dr. J. Michell Clarke showed a patient with a Lesion of the Cauda Equina and another with a Lesion of the Lumbar Cord.—Dr. F. H. Edgeworth showed a case of Cretinism that was improving under thyroid treatment.—Dr. Walter C. Swayne showed a Calcareous Mass removed from the Broad Ligament.—Mr. G. Munro Smith showed a specimen of Scrotal Tumour with microscopic section, also a skiagraph showing numerous Foreign Bodies in the Hand.—Mr. A. W. Prichard read notes of three cases of Vesical Calculus that he had had within as many weeks and showed the stones removed.—Mr. J. Dacre related two unusual cases of Pneumothorax.—The cases, specimens, and papers were discussed by the members present.

Reviews and Notices of Books.

Infection and Immunity, with special reference to the Prevention of Infectious Diseases. By GEORGE M. STERNBERG, M D., LL.D., Surgeon-General United States Army (retired). London: John Murray. 1903. Pp. 293. Price 6*s.* net.

THIS work forms one of the Progressive Science Series edited by Mr. F. E. Beddard, F.R S. The series is intended for the general reader and not for the specialist. It is well to remember this as otherwise the title of the work, in conjunction with the name of the author, may prove somewhat misleading. The object of the book is "to state the main facts, so far as they have been established, with reference to infection and immunity, with the practical object in view of indicating the measures necessary for the prevention of infectious diseases." We find, therefore, the subject of disinfection treated somewhat at length and no attempt is made to discuss the theories of immunity or to give any account of the results of recent investigations with regard to antitoxins, agglutinins, precipitins, and other lately discovered bodies of this type.

The book is divided into two parts. The first part treats generally of infection and disinfection and, very briefly, of natural and acquired immunity. The second part occupies more than two-thirds of the book and treats the principal infectious diseases individually. Each chapter gives, for the size of the work, a somewhat detailed historic account of successive epidemics of the disease dealt with, followed by a short account of the micro-organism associated with the malady. It is, however, to the epidemic spread of the disease and to the methods employed in checking its ravages that attention is chiefly directed. Throughout the book the information with regard to prevention is definite and practical and use is made of the reports drawn up by various sanitary authorities dealing with tuberculosis, diphtheria, and yellow fever. As might be expected from one so long associated with preventive medicine, there is a strong personal note permeating the work. Two interesting claims to priority are made. The author suggests that he ennunciated the theory of phagocytosis in 1881, three years before Metchnikoff's first paper on the subject, while to Dr. W. F. A. King of Washington is attributed the theory of malarial infection by mosquito bites.

The book is well printed on good paper and includes a small number of illustrations. The work will certainly be valuable in that it gives non-medical readers accurate information both as to the means by which infectious diseases are spread and the methods which may best be adopted to prevent them from becoming epidemic.

Asthma in Relation to the Nose, with Notes of 403 Cases. By ALEXANDER FRANCIS, M.B , B.C Cantab. London: Adlard and Son. 1903. Pp. 136 Price 5*s.* net.

THIS book is apparently an expansion of a paper read before the Clinical Society in 1902 and is intended as a contribution towards the investigation of a connexion between asthma and the nose. Dr. Francis hopes to demonstrate that the connexion is something more subtle and important than a "mere causal relationship." He believes that there is a morbid connexion between the nose and the respiratory centre, which maintains the centre in such an unstable condition as to allow peripheral irritation to provoke an asthmatic reflex. On this assumption he believes that dyspnœa can be profoundly affected by intranasal treatment, even though the originating irritation of an asthmatic attack be gastric, cardiac, bronchial, renal, or nasal, or arise in any other sensory organ. The special part of the nasal mucous membrane which has this controlling influence upon the respiratory centre is, he considers, "an area situated on the septum nasi." Dr. Francis writes as an enthusiast, hence it is not surprising to find occasional inconsistencies. Thus on p. 35 he regards the remark "all my trouble comes from my digestion" as one of the most hopeful signs in forming a prognosis, while a few pages further on he says he has found that "no class of case gives better results" than "bronchial." He is not sanguine about the permanency of the relief obtainable by the removal of mucous polypi, though he acknowledges that there is "no class of cases where relief of all asthmatic symptoms can be, in some instances, more speedily and completely obtained." The treatment he advocates consists in drawing a line with a galvano-cautery point from a spot opposite to the middle turbinated body forwards and slightly downwards for a distance of rather less than half an inch. This is repeated in a week on the other side and afterwards on alternate sides at intervals of ten days or a fortnight. In his chapter on treatment he speaks well of "antimony" and of "ammonium." Presumably he means some particular compounds and it would have been more satisfactory not to leave the choice to the reader. Of the notes of the 402 cases and of the summary of an additional number of 93 cases which are quoted to support the author's view of the efficacy of his treatment it is somewhat difficult to speak. The 402 cases were all seen and treated between November, 1896, and March, 1902; the 93 cases were seen by a colleague during the author's absence from Brisbane. Asthma must be curiously prevalent in Queensland to afford such frequent opportunities for observation or else there must be some local peculiarities of nomenclature of disease.

Squint occurring in Children: an Essay. By EDGAR A. BROWNE, F.R.C.S. Edin., Lecturer on Ophthalmology, University of Liverpool; assisted by EDGAR STEVENSON, M.D. Aberd., Demonstrator of Ophthalmology, University of Liverpool. London: Baillière, Tindall, and Cox. 1904. Small 8vo. Pp. 74. Price 2*s.* 6*d.*

THIS little brochure contains the matured views of Mr. Browne and Dr. Stevenson on the etiology and treatment of squint. The authors do not pretend to describe all the varieties of this affection but limit themselves to a consideration of the ordinary concomitant convergent squint of childhood, believing that a thorough appreciation of the phenomena of this form of squint both in regard to the order of their occurrence and the concomitant conditions which are conducive to the development of the symptoms will prove more serviceable to the learner than a multitude of statistics. It is pointed out that hypermetropia is of common occurrence in very young children and that they consequently habitually exercise their accommodation which has a tendency to strengthen the internal recti, so that when they begin to examine near objects closely an inversion of one eye or a periodic squint is observed and this passes easily into a fixed habit and becomes a permanent squint. Under appropriate treatment with glasses a secondary periodic squint may be re-established which ends in recovery. The authors are strongly disposed to believe that amblyopia is very frequently associated with squint. And there can be no doubt that defective vision of the squinting eye is of common occurrence. The natural conclusion is that the cause of the defective vision should be carefully investigated, however young the child may be, and any error of refraction that may be present should receive immediate and careful attention. By the prescription of lenses correcting the defect recovery may in many cases be effected and the performance of the various operations that have been devised, whether of the nature of tenotomy of the overacting muscle or advancement of the opposite muscle, be avoided. The difficulties attendant upon determining the appropriate glasses in very young children, it is shown by the authors, may be overcome with patience and the employment of retinoscopy. Astigmatism is often present in the faulty eye.

In an appendix the authors recommend the abolition of the slate and school-book and the replacement of these instruments of education by the black board and are of opinion that the practice of bimanual exercises should be adopted. The after-histories of several cases of squint treated without operation are given by Dr. Stevenson. The book is sensibly written.

LIBRARY TABLE.

Bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital.—No. I., issued 1903. Philadelphia. Pp. 88.—In a preface we are informed that "this publication is the result of a deep interest taken in the promotion of the laboratory by the late Dr. J. G. Morton and the kindness of Mr. Frederick Fanning Ayer, who generously provided the funds for its maintenance." The "Bulletin" will be used as a means of publishing the results of investigations which have been carried out in the laboratory in connexion with the Pennsylvania Hospital and will be issued at such intervals as are thought necessary. It is further announced that a copy of the "Bulletin" will be sent "to those interested in its contents who will make a request for it." The formation of such an institution as the "Ayer Clinical Laboratory" is indeed a matter of congratulation for the Pennsylvania Hospital. If private munificence were more frequently devoted to such excellent purposes medical science would be greatly benefited. The volume now before us contains an elaborate essay on the Pathological Histology of Hodgkin's Disease, with a report of a series of cases, by Dr. W. T. Longcope, resident pathologist of the Pennsylvania Hospital, which shows evidence of arduous and painstaking work. Dr. Louis M. Warfield contributes two short articles entitled "The Report of a series of Blood Cultures in Typhoid Fever" and "A Mild Case of Acute Dysentery yielding Bacillus Dysenteriæ (Shiga) in Large Numbers," and a third in conjunction with Dr. J. K. Walker on Acute Ulcerative Endocarditis caused by the Meningococcus (Weichselbaum).

Practical Physiological Chemistry. By J. A. MILROY, M.A., M.D. Edin., Demonstrator of Physiology, Queen's College, Belfast; and T. H. MILROY, M.D., B.Sc. Edin., F.R.S. Edin., Professor of Physiology, Queen's College, Belfast. Edinburgh and London: William Green and Sons. 1904. Pp. 201.—This book does not pretend to be anything more than a practical work although the authors have very properly entered into short theoretical explanations where such seemed to be essential for the proper understanding of a practical experiment. There are four sections, the first two dealing with qualitative and quantitative examinations respectively, while the third section is an appendix containing a table of reagents, of wave lengths and other physical constants, and the fourth section deals exclusively with schemes for the detection of an unknown substance. We regard these schemes as an important feature of the work as applied to the search in an unknown solid, or mixture of solids of physiological importance, for proteids, carbohydrates, and other substances. In the list of precipitants of proteids we find that neither bromine nor chlorine is mentioned. We note also that in the description of the Pettenkofer's test for bile salts cane sugar is directed to be used. Glucose is much better as it has scarcely any tendency to char with the sulphuric acid and thus to obscure the reddish-violet tint which is formed with such a mixture in the presence of bile salts. The authors point out in the chapter on the estimation of sugar in urine that various attempts have been made to render the determination of the complete reduction of the copper solution easier of observation. In this connexion we may refer them to the simple expedient suggested by Mr. S. A. Vasey in a note in The Lancet of June 20th, 1903. It consists in adding a white inert powder, such as chalk, to the Fehling mixture. In this way the chalk carries the fine separated cuprous oxide rapidly to the bottom of the hot fluid so that the precise point at which the blue colour disappears can be determined. The book forms an excellent basis of a practical physiological course and the illustrations are beautifully executed.

The Sale of Food and Drugs Acts with Notes and Cases. By Sir William J. Bell LL.D., H. S. Scrivener, M.A., and C. F. Lloyd. Fourth edition. London: Butterworth and Co. 1903. Pp. 276.—The issuing of several new orders and regulations under the Sale of Food and Drugs Acts by the Local Government Board and the Board of Agriculture, as well as the fact that some fresh cases of importance have been decided, have rendered the publication of a fourth edition of this useful work necessary. The present edition has been thus brought completely up to date and we find that it contains notes on some recent cases presenting special points of interest. In summarising the recommendations of the Departmental Committee on Food Preservatives, the authors remark that "up to the present time (October, 1903) none of these recommendations have been carried into effect." We have before pointed out that there can be no justification for delay in the matter of embodying these recommendations in the statute. This book is an excellent legal guide to the public analyst and affords much useful information on analytical and chemical points to the legal profession.

The Cornish Riviera.—An illustrated pamphlet urging the claims of Cornwall upon those who desire to enjoy a mild climate in winter and to avoid extreme heat in summer has been issued by the Great Western Railway Company and contains an appendix with particulars of the trains and motor-car service by which various points can most easily be reached. The portion of the letterpress devoted to the advantages of the climate mentions as a work extolling it the "Guide to Mount's Bay and the Land's End," written by Dr. John Ayrton Paris in the year of the battle of Waterloo. Dr. Paris at that time practised at Penzance, where he was the first secretary of the Royal Geological Society of Cornwall and whence he returned in 1817 to London to become in 1844 the President of the Royal College of Physicians of London. He wrote in the days when it took nearly 60 hours of coach travel to reach Penzance from London and to him and to other medical men of more modern date Cornwall has owed many of its numerous visitors. The climate of South and West Cornwall, even in years like the present one, is delightful on account of the warmth and geniality of the days which are fine, but even in Cornwall no one can expect to be free from winter's storms. It must be remembered, however, that the varieties of narcissus and other spring flowers already coming to the London market are being grown in West Cornwall and the Scilly Islands in the open air and that flowering shrubs not often seen further north bloom there throughout the winter. For those who desire a mild climate but at the same time are able to enjoy out-door amusements Falmouth's harbour and bay afford ample scope for safe sailing throughout the winter, except, of course, in very stormy weather, and among the many golf-links those at Lelant, accessible from St. Ives or from Penzance, may be mentioned as situated upon raised sandy ground. Cornish dairy produce is famous and the county is one where many cottagers still bake their own wholesome bread, usually in an open pan upon the hearth.

The Englishwoman's Year Book, 1904. Edited by Emily Janes. London: Adam and Charles Black. Pp. 352. Price 2s. 6*d.* net.—This volume is a worthy companion to "Who's Who?" and contains a vast amount of information upon every subject connected with the employment of women, whether as regards philanthropy, science, professions, business, or amusement. It has an admirable index and we are glad to see that the advertisements are as carefully edited as the rest of the book, with the exception of one dealing with magazines and the like edited by a lady who is neither more nor less than a quack practitioner.

JOURNALS AND MAGAZINES.

The British Journal of Psychology. February, 1904.—The first number of this new periodical has reached us and serves to remind us how modern, at any rate in this country, the systematic study of psychology is. It is only quite recently that it has attained to the position of a positive science. But within the last 15 years, say in their foreword Professor James Ward and Dr. W. H. R. Rivers, the joint editors of the new venture, 40 psychological laboratories have come into existence, lectureships on the subject have been founded, societies have been instituted, while seven serial publications devoted entirely to psychology have appeared in other countries. The new magazine has therefore been started with the full belief that it is required. Professor Ward's opening paper on the Definition of Psychology is an admirable introduction to a science which in an exact sense is most difficult to appreciate, even though everybody can tell in a general way what psychology is about. An interesting paper follows by Professor Sherrington upon "Binocular Flicker." This is a record of experiments inquiring into the influence exerted on the reactions of "retinal point" by certain forms of activity at the corresponding point of the other retina. (By "retinal point" is understood the retino-cerebral apparatus engaged in elaborating a sensation in response to excitation of a unit of retinal area.) Dr. J. Lewis McIntyre, lecturer on comparative psychology in the University of Aberdeen, contributes to the history of psychology a study of the sixteenth century Italian philosopher Telesio. The volume terminates with a paper by Mr. W. McDougall, reader in experimental psychology in University College, London, upon the Sensations excited by a Single Momentary Stimulation of the Eye.

The Practitioner in its February issue continues Dr. A. E. Wright's very complete and instructive article upon anti-typhoid inoculation. In the present contribution he shows how the vaccinating elements in the typhoid culture are maintained intact after exposure to a temperature of 60° C. The efficacy of the elements in the red corpuscles which induce an elaboration of hæmolytic antitropins in the organism is somewhat diminished by exposure to this temperature; and exposure to a temperature of 72° C. completely abolishes the immunising properties of the red blood corpuscles. Dr. Arthur Whitfield contributes the first of two lectures on eczema and gives details of one or two remarkable instances of idiosyncrasy in the matter of hypersensitiveness of the skin. The nervous origin of some cases of eczema is alluded to in another article entitled "Hypnotism" in which a cure of such a case by this means is mentioned. This article on hypnotism deals mainly with Dr. J. Milne Bramwell's recent work on the subject.

New Inventions.

APPARATUS FOR MAINTAINING ARTIFICIAL RESPIRATION.

THE appliance represented in the accompanying illustrations is intended principally for keeping up artificial respiration and has been devised by Dr. Rudolf Eisenmenger of Piski in Hungary. It consists essentially of a relatively high rigid dome of such a length as to extend from the upper part of the sternum to nearly the pubic region. It is attached to the patient by straps which completely encircle the body, and in order that the junction may be air-tight it has indiarubber packing along the lower side of the margin and, moreover, has flexible lateral flaps which reach almost to the patient's spine. In Fig. 1 the dome and the indiarubber packing are shown in section, while the straps and the borders of the flaps are marked by dotted lines. On the summit of the dome there is a short tube giving access to the interior and connected to a long flexible tube which leads to a pair of bellows lying on the floor, as shown in Fig. 2. When the air within the dome is exhausted by the bellows the abdominal wall rises and air is drawn into the lungs; on the other hand, the forcing of air into the dome by the bellows causes the lungs to be emptied. Evidently an effect will also be produced on the flow of blood to or from the heart. Dr. Eisenmenger says that the apparatus can be used not only for the treatment of persons suffering from asphyxia but also for the performance of abdominal massage. It is easily applied and is portable enough to be carried in a hand-bag, the total weight being from 20 to 30 pounds.

FIG. 1.

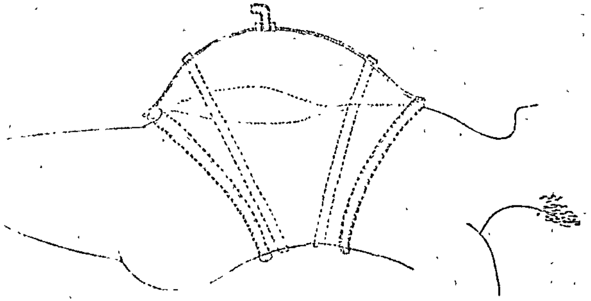


FIG. 2.

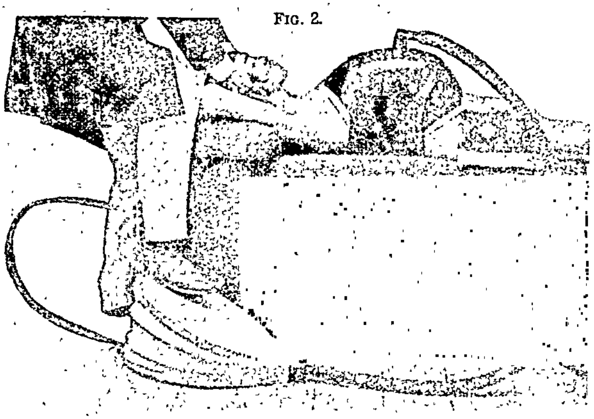
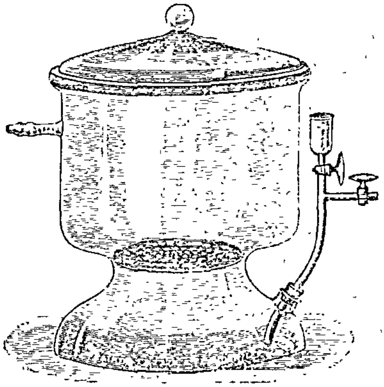


A NEW ANAEROBIC APPARATUS.

THE following is a short description of a new anaerobic apparatus which I had designed and which is giving excellent results It consists of a large, strong glass jar having a constriction near its base and a ground closely fitting lid on top, the sides of the jar projecting above the height of the lid for half an inch. Two lateral openings are let into the vessel. The first, situated one inch below the lid, has a short strong tube fused in, which has a short piece of pressure tubing firmly attached and furnished with a Hofman's pinchcock, and this is when required attached to an exhaust pump. The second opening situated below the constriction of the vessel, has a perforated, tight fitting rubber cork through which passes a bent glass tube reaching to within a quarter of an inch of the floor of the jar. The other end has two arms, one of which is a reservoir for caustic potash solution, the other leading to the hydrogen supply. Both arms are furnished with stopcocks. To work the apparatus, a sufficiency of pyrogallic acid is first put into the reservoir at the foot of the vessel, the perforated porcelain rest is placed on the constriction, and the plates or tubes to be cultivated are placed upon this rest; the glass lid is well smeared with vaseline and replaced and pressed firmly down. Into the ledge left between the top of the lid and the top of the vessel wall is placed soft paraffin soap which almost covers the whole surface of the lid. Now connexions are made with the exhaust pump and hydrogen apparatus and it is seen that the stopcocks of the hydrogen supply tube and the potash supply tube are both closed. The pinchcock of the exhaust tube is opened and all air exhausted, the pinchcock is shut and the hydrogen stopcock is opened to admit hydrogen, this process being repeated six times to insure a complete hydrogen atmosphere; then, closing the hydrogen stopcock, a little of the hydrogen is exhausted by means of the exhaust pump, just enough so as to have a slight negative pressure within the vessel. Now the reservoir is filled with potash solution and the stopcock is opened to allow the solution to flow gradually into the vessel. Enough is run in so that the end of the tube will be below the resulting mixture and so act as a seal to it. It is best to run in a little water after the potash solution so as to clean the tube and obviate the effects which it is likely to have on the glass.



The apparatus has been made and is supplied by Messrs. Baird and Tatlock, 14, Cross-street, Hatton-garden, London.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 20, 1904.

The Rainfall and Mortality of 1903.

ALTHOUGH, taking England and Wales as a whole, the rainfall of 1903 was exceeded by that of 1852 and 1872 the downpour of the year recently ended was sufficiently unusual to justify us in inquiring how far and in what direction it may have influenced the mortality statistics. The inquiry is more particularly called for seeing that the rainfall of 1903 came after 15 years of remarkably low rainfall and that it exceeded the average of the previous 15 years by at least 35 per cent.,[1] a fact which increases the value of a comparison of the statistics of 1903 with the average of the previous ten years. In endeavouring to gauge the effects of the rainfall of 1903 it is well to bear in mind the fact that in some parts of England, such as the Cumberland hills, the annual rainfall may amount to as much as 150 inches, while in the hills to the north of Bengal no less than 600 inches have been recorded. The statistics of Bengal do not suffice to enable an examination to be made of the disease values of this rainfall and the question therefore arises whether in our own country, where the records both as regards rainfall and deaths are at least as trustworthy as in any other nation, it is possible, with only the data at present available, to determine even approximately the effect upon the death-rate of the wet year 1903.

Let us consider what are the physical consequences of rainfall and what are the results which may be expected to accrue from them. In the first place, as is well illustrated by the remarkable clearness of the atmosphere after rain, the falling water washes from the air and from surfaces upon which it impinges the dust and micro-organisms which accumulate therein and thereon in consequence of the operations of man and animals and of atmospheric currents. This being so, it is reasonable to anticipate that, *ceteris paribus*, rainfall tends to reduce the prevalence of, and hence probably the mortality from, certain air-borne diseases. But against this consideration has to be placed the fact that protracted bad weather tends to keep people indoors and thereby to enhance the opportunities of contracting air-borne infection. Again, rainfall in proportion to its degree maintains in a condition of moisture collections of dust and refuse from which particles in a dry state are easily detached and carried by the wind. In this fashion rainfall may be considered to reduce the chances of the infection of food by pathogenic organisms, while, further, in a somewhat similar manner it diminishes the prevalence of dust-carriers, such as the common house flies and other insects. This reduction of dust-carrying agencies might be expected to be reflected in the death returns in a diminution of that disease which is so intimately associated with polluted milk and other foods—i.e., diarrhœa—and probably the enteric fever rates might be expected to be influenced favourably, at least in some degree, by the same agencies. On the other side has to be placed the influence of rain both in the direction of the flushing of sewers, the discharge from storm overflows, and the washing of manurial surfaces into rivers and into reservoirs fed by pastured or cultivated catchment areas, agencies which might be expected to carry pathogenic organisms and much mineral detritus into water-supplies. The turbidity of drinking water after periods of heavy rain is a matter of common observation and such turbidity has, as our readers are aware, not infrequently been associated with outbreaks of enteric fever and diarrhœa. Finally the rise in the level of the subsoil water and the general increase of surface moisture might augment the death-rate from diseases such as diphtheria, pulmonary tuberculosis and other bronchial complaints, as also from chronic rheumatism and—according to some authors—from measles and whooping-cough.

The official statistics are not yet available to enable all these diseases to be examined but the recent issue of the Registrar-General's last quarterly return renders it possible to show in what manner certain diseases have behaved in the several quarters of 1903. It is, of course, important to remember that the rainfall of one quarter may influence the vital statistics of the following quarter and that the rainfall of the whole year 1903 may not be without its effect upon the statistics of 1904. If we take a general view of the figures for 1903 as a whole the interesting fact stands out that the general death-rate was the lowest on record—i.e., 15·4 per 1000—and compared with the average rate in the ten years 1893–1902 it shows a decrease of 2·2 per 1000. The inference which may be drawn from this fact is that the wetness of 1903 did not exert an unfavourable influence upon the general death-rate of the year. It is, however, desirable to look into the figures a little more in detail but unfortunately this is not yet possible save in regard to certain diseases. With a view of showing at a glance in what manner the death-rate for the several quarters of 1903 compares with the rates for the ten previous corresponding quarters we have constructed a table relative to (1) the general death-rate, (2) "fever," (3) diarrhœa, and (4) diphtheria. In the first column of each group are the quarterly rates for 1903 and in the second column there are figures showing to what extent the rates for 1903 were above or below the average for the ten preceding quarters. The rates in all cases are rates per 1000.

Quarters.	General death-rate		"Fever."		Diarrhœa.		Diphtheria.	
	1903.	+ or − average.	1903.	+ or − average.	1903.	+ or − average.	1903.	+ or − average.
1	16·8	−2·9	0·09	−0·05	0·17	= average	0·23	− 0·06
2	14·9	−1·7	0·08	−0·03	0·17	− 0·06	0·16	− 0·06
3	13·9	−3·0	0·10	−0·09	1·16	− 1·10	0·15	− 0·09
4	16·2	−1·1	0·14	−0·11	0·49	+ 0·08	0·17	− 0·13

From this table it would appear that almost without exception the quarterly rates show a very material reduction on the averages for the corresponding quarters of preceding years, and although we cannot spare space to reproduce the tables which we have drawn up relative to infantile mortality, whooping-cough, measles, and scarlet fever, we may add that, as with the figures in the above table, there was almost invariably a fall in the average rates. Whether these general reductions are in point of fact ascribable in large measure to the excessive rainfall alone is a matter upon which we shall express no definite opinion. Rainfall is but one of the several meteorological factors which may either promote or retard the vital processes of micro organisms. The figures, so far as they go, do not support a view that a wet year promotes the spread of any of the diseases to which reference has been made. When, however, the *Registrar-General's annual report for 1903* is issued it will be possible to take a more detailed view as regards the death-rates and the rainfall in certain specified parts of the country.

The Administration of Opium in Pneumonia.

The influence of waves of thought upon prevailing practice is demonstrated more fully with pneumonia than with any other disease. The range of surgery has been incalculably extended of late and physicians owe much of their conceptions of the processes of disease to researches which primarily lead to results in the domain of surgery. With ever increasing knowledge of the etiology of pathological conditions it is natural that greater precision of treatment should be required. Every fresh discovery which throws light upon the causation of disease must necessarily be followed by further thoughtful investigation of the adequacy and suitability of the methods of treatment which have hitherto been generally adopted. Treatment is always an indication of current conceptions of morbid processes. Every advance probably induces momentary scepticism of the value of routine treatment which has been adopted as the outcome of experience, and this scepticism is an aid to progress when it leads to the correction of error and to the discontinuance of antiquated methods, but it is a hindrance when, in the desire to seek novelty, it hastily discards all treatment before what threatens to become a new formula—namely, the proclamation that a self-limited systemic infection must come to a natural ending and therefore needs no treatment.

When pneumonia was regarded as an acute inflammatory affection due to cold it was treated vigorously by bleeding and by purgatives, which without doubt relieved pain and diminished arterial tension. On account of the dry burning heat of the skin diaphoretics were sometimes employed, the most important being tartar emetic. Then followed the group of stimulant expectorants to facilitate the removal of the exudation. But it was soon realised that drugs were scarcely required. Indeed, the extravagant claims put forward for homœopathy paved the way for the recognition of a normal definite crisis in pneumonia independently of active interference, and this in turn was a step towards the subsequent discovery of the presence of micro-organisms and to the numerous attempts which have been made to utilise this knowledge. For the present most clinical observers are convinced that with our known resources it is impossible to curtail the duration of the fever which is, indeed, regarded in some quarters as a natural effort to limit and to control the development of micro-organisms. Accordingly, while some, on the self-limited systemic infection theory, think there is nothing to be done, others turn more hopefully to symptomatic treatment. Of late years there have been many indications of uneasiness concerning symptomatic treatment in pneumonia, and more than one observer has declared his conviction that it cannot safely be pursued on ordinary lines. Many maintain that several distressing symptoms are really conservative in their origin and that any interference with these may be followed by dangerous results. The pyrexia *and the dyspnœa of pneumonia would under such reasoning* be regarded like the diarrhœa of typhoid fever as being beneficial within reasonable limits, and therefore to be checked only when they appear to be excessive. In nearly every case of pneumonia, if symptomatic treatment is to be adopted, there are probably numerous temptations to employ opium or morphine. The severity of the pleuritic pain at the outset seems to demand the adoption of measures calculated to afford relief, and since opium is ordinarily the drug which is relied upon for this purpose it is probably the one to which thoughts will first turn. It is, moreover, the drug which is definitely recommended in many text books and works of reference. One favourite text book distinctly advocates the hypodermic injection of morphine for the relief of the stitch in the side at the onset of pneumonia and further recommends that when the disease is fairly established Dover's powder should be given to check cough and so to alleviate pain.

Nearly two years ago[1] we had occasion to refer to Sir William T. Gairdner's view of the extreme danger of opium in pneumonia. In a paper published in the *Glasgow Medical Journal* for April, 1902, he maintained that the safety of the patient depends upon the respiratory nerve centres being kept, as it were, "wide awake." His views, with which we then expressed our concurrence, have recently received confirmation from Dr. Stephen Smith Burt[2] who discusses the purposes for which opium has frequently been administered in pneumonia and gives his reasons for regarding it as a dangerous drug in this disease. He mentions its employment to relieve pleuritic pain, but for this purpose strongly advocates the local application of an ice-bag, or a hot poultice, or strapping the affected side of the chest, or if these fail he recommends dry-cupping, using a large common tumbler. With regard to the administration of opium to allay cough he pertinently remarks that the average cough of pneumonia with expectoration for obvious reasons should be rather promoted than suppressed. Similarly he contends that when given in this disease to quiet restlessness opium is prejudicial, since under these conditions restlessness is preferable to somnolence. Dr. Burt reminds us that opium, except in doses that are infinitesimal, depresses and finally paralyses the centres of respiration and that it checks every secretion save that of the integument. He holds that in pneumonia the existence of the patient depends upon a maintenance of the integrity of the respiratory centres, together with the powers of elimination. Sir WILLIAM GAIRDNER in the paper above referred to said that he had repeatedly seen toxic symptoms from very moderate doses of opium in certain stages of pneumonia and that, especially towards the crisis, he had learned to dread it more than almost any other drug. In view of this experience it is interesting to note that the fatality mentioned by Dr. BURT resulted from the hypodermic injection of morphine when the patient was apparently on the road to recovery—that is, presumably, just before the crisis. The facts and arguments against the employment of opium at this stage seem so strong that they demand thoughtful revision of the recommendations at present to be found in text-books; greater emphasis should be placed upon the risks incurred, except possibly at the onset of the disease, and greater stress might well be laid upon the amount of relief which is then frequently afforded by the local application of ice or by the abstraction of blood by leeches. The immediate ease which results from the use of morphine for pleuritic pain in pneumonia should not entail disregard of warnings against its employment based on experience and on reason.

◆

The Future Position of the Dental Profession.

IN the issue of THE LANCET of May 23rd, 1903, p. 1456, reference was made to the question of a dental degree in the University of London. In that article the view was expressed that if a degree in dentistry were instituted it should only be in conjunction with the M.B. and B.S. Quite recently—namely, on Jan. 23rd—an extraordinary general meeting of the British Dental Association was held to consider the expediency of degrees in dentistry and after lengthy discussion it was decided by a majority of two to one that such degrees were undesirable. It is held by the advocates of such degrees that the decision arrived at will not influence in any way the various universities in forming their opinions. If such is really their view it is somewhat difficult to understand their position in endeavouring to induce the British Dental Association to memorialise the Senate of the University of London to grant degrees in dentistry. We consider that the view expressed by the majority of the meeting should have some influence with the University of London and other universities and we cannot help feeling that the various institutions will be guided by the opinion held by those best qualified to discuss this problem. They can hardly force degrees upon an unwilling profession, especially as such a course would probably lead to a serious breach in what is now a united profession. In endeavouring to arrive at a wise decision on this subject, which apparently is causing quite a storm in the dental world, it would be well for those engaged in the contest to keep clearly in view the relation of dental surgery to medicine. Regarded from a broad point of view the whole matter resolves itself into the question whether the practice of dental surgery is to retain its position as a part of medicine or is to be relegated to the position of an isolated profession. That the latter condition is the distinct and avowed wish of some of the supporters of the dental degree is undoubted but this view is diametrically opposed to the opinions held by the most competent teachers in this country. It is only natural with two such schools of thought that the ideas of training the student should also be widely different. The former school insists that the training should be in the main mechanical and views the need of a good medical training as apparently quite secondary. The latter school takes a broader view of dentistry and naturally considers it of the greatest importance that those dealing with the diseases of any part of the body should possess a thorough knowledge of general pathology and have a firm foundation on which to practise their specialty. It is not difficult to see how this diversity of opinion has been brought about if we consider the position of dentistry in the middle of the last century. Then dentistry consisted almost entirely of extraction and the substitution of artificial dentures. It was a trade and the mechanical element was writ large because the only dental practice known was mechanical. Increased knowledge of caries, of the diseases of periodontal membranes, of the relationship of dental disease to general systemic conditions, and of oral deformities to nasal affections has all tended to broaden the scope of dental surgery and so has introduced into its therapeutics means of treatment which are not solely mechanical. A point also to be considered in dealing with this magnification of mechanical ability as the main idea in training is the influence which rational therapeutics must exert in the development of the future treatment of the teeth. The student educated with higher ideals than heretofore will endeavour to carry into his work that highest ideal of all—viz., "prevention." That should be his watch-word and the effect of prophylaxis in dentistry will be the simplification in a marked degree of the operations which he is called upon to perform. His work will be of a far more simple character than heretofore and the elaborate technique called for in the operations of the present day will not be required to anything like the same extent. It may be argued that such a state of affairs is far away. Even if that be so, its realisation will be quicker the broader the views of treatment given to the future dental surgeon and the greater the impression on his mind that mechanical operations are not the sole agents of treatment.

The broader the foundation of education the less we shall hear of dentistry as a separate profession and the more it will be apparent to the intelligent that its correct place is in the fold of medicine. Another reason why in the minds of some the medical training is quite secondary to the more purely technical training is due in a large measure to the extraordinary immunity of the oral tissues to infection. The removal of a tooth, which is a minor surgical operation, is in a great measure free from all those complications likely to follow any other operations. It is this condition which blurs the visions of those who fail to see that the practice of dental surgery is but part of the practice of general medicine. If tooth extraction and other dental operations were more liable to be followed by complications we should hear but little about the secondary importance of the medical training. It is hardly necessary to repeat here the arguments we have so often advanced to show that dentistry is but a specialty of medicine and can best be rationally practised by those possessing a thorough knowledge of disease in general.

Holding this view we fail to see that any advantages can possibly be gained by the institution of dental degrees unless granted to holders of medical qualifications. It is admitted, even by the advocates of the dental degree pure and simple, that the present qualifying examinations are sufficient for the average practitioner and the principal argument advanced is that dental degrees would be the means of stimulating research, which is to be done by requiring a higher standard of technique and a broad acquaintance with pathology and the principles of surgery. The idea of stimulating research by instituting a dental degree is hardly worthy of consideration. The desire to do research work is not the product of examination. Still further, increased technique in dental operations will not tend to foster research but it will tend to make the possessor of the dental degree regard himself as being on a higher plane than the licentiate in dental surgery. It is argued, too, that the degree would be of a higher educational value than the ordinary qualifying examination. That may possibly be the case at the University of London but there is no proof that other universities, which would follow suit, would insist on even such a high standard as that required by the Royal College of Surgeons of England. The institution of dental degrees will certainly not be for the welfare of the public. At the present time the public are beginning to recognise that the diploma indicated by the letters L.D.S. is the hall-mark of a dentist and so far the quacks and charlatans have been unable to turn these letters to their own use. Let the universities grant degrees and the public will be bewildered with innumerable letters; it will be excessively difficult for them to discriminate between genuine and spurious appellations. Still further, the possibility of one of the universities granting a doctorate in dental surgery must not be lost sight of and the institution of such a degree would do endless harm and would lead the already too gullible public to believe that the holder of such a degree was a medical man. If the universities are anxious to grant qualifications they can grant diplomas similar to the licence in dental surgery and we must not forget that under the Dentists Act this licence is the only diploma registrable in this country. In order to overcome this difficulty it has even been suggested that at the conferment of the degree a licence in dental surgery should be presented. This, surely, can be looked upon in no other light but as an evasion of the Dentists Act and we feel that no university would be guilty of such an action. The conferment of degrees in dentistry on those not holding medical qualifications would tend to separate dentistry from medicine rather than to increase the bond of union.

Let us for a moment glance at the position of other specialties. In public health a diploma is given by several examining bodies but only to those holding medical qualifications. Quite recently the University of Cambridge has decided to institute a degree in tropical medicine but naturally only to the medical practitioner. If degrees were granted in such specialties as diseases of the eye, throat, and nose they would only be to medical practitioners. Dentistry, then, is to stand alone as not requiring any medical qualification. To those advocating the degree this would probably be acceptable but to the large body of dental practitioners and in the interests of dental science the step would be disastrous. It is therefore of great importance that the dental profession should place before the university authorities the many objections to such degrees in order that the question may receive the attention that it deserves.

◆

London Thoroughfares.

THE last sessional meeting of the Sanitary Institute of Great Britain was usefully devoted to papers and discussions upon the state of streets and thoroughfares in relation to public health, and hence to an endeavour, on the part of several competent authorities, to recall town councillors from the contemplation of vast schemes of municipal trading or manufacture, and to direct their attention to the comparatively humble duty of effective scavenging. Perhaps the most important contribution laid before the meeting was contained in a paper by Dr. LOUIS C. PARKES, the medical officer of health of Chelsea, who dwelt emphatically upon the disease producing properties inherent in the peculiar compound which, according to the state of the weather, may be described either as London mud or as London dust and which, in the former condition, clings lovingly to the lower portions of female apparel, while in the latter it is plentifully inhaled by both sexes alike, and is carried by currents of air into larders and other receptacles of food, in such a manner that the bronchial mucous membranes of urban dwellers have no unfair advantage over the gastric and the intestinal. The methods and circumstances of the distribution are of such a kind as to render it extremely difficult to trace any single case of disease either to the inhalation or to the swallowing of the abundantly diffused material, but the nature of this material forbids us to doubt its capability of doing harm whenever opportunity is afforded. The open dust carts and the excreta of dogs and cats, to which Sir HENRY THOMPSON has called attention, supply an abundance of the bacteria of putrefaction and of the ova of intestinal parasites, while the bacteria of specific infectious diseases can seldom be entirely absent from the general *olla podrida*. When clouds of visible coarse powder, interspersed with fragments of paper or of cabbage leaf, are blown into our faces from a passing dust cart we are apt to forget the state of fine division which the constituent particles of these clouds will presently assume, and in which they are probably more likely to be hurtful than even in their original condition. Many attempts have been made, with very partial success, to exclude dust from the cases containing the more valuable books in the library of the British Museum, and that which finds entrance and can be collected in impalpable powder from the surfaces of the leaves always exhibits under the microscope evidences of its sources in Bloomsbury in the shape of fragments of horse droppings, of iron, and of granite. Other treasures would, no doubt, occasionally reward a complete examination, and among these would almost certainly be various bacteria in a condition to multiply as soon as external circumstances became favourable to them. Dr. PARKES drew a lesson from the comparative healthiness of 1903, stating that the continued wet, and especially the character of the frequent very heavy rains, had washed away from the metropolis a large proportion of the dirt which is usually inhaled and swallowed by the inhabitants; and he thence inferred that macadamised roadways should, as soon as possible, be superseded by wood or by asphalt and that these should be effectively cleansed by daily washing. This course is already pursued within the boundaries of the City.

With regard to town dogs Dr. PARKES is even more emphatic than Sir HENRY THOMPSON, for he describes them as "an unmitigated nuisance." He further declares that the present state of the footpaths, in relation to canine excreta, is largely due to the disappearance of an industry by which these excreta were formerly collected for use in tanneries and which has now been superseded by the products of an artificial or laboratory dog made in Germany. The chief blame must, however, be laid upon the local authorities who, as a rule, totally neglect that duty of cleansing footpaths which the law clearly imposes upon them. The real grievance in the matter is that the individual householder has no easy remedy against the local authority and that any proceedings taken against this authority would be defended at the cost of the rates. No single amendment of the law would be so valuable, in relation to the health of towns, as a power given to any householder to apply to a magistrate for an order directing negligent authorities to do their duty and throwing the cost of the proceeding upon the shoulders of the negligent persons whoever they might be. Dr. PARKES further advocates, what the *Times* had suggested a month before, the imposition of a municipal tax upon dogs, in addition to the national tax, and as a means of meeting the expenditure rendered necessary by their presence in towns. The ownership of a dog has a remarkable tendency to convert even a philosopher into an unreasoning being and the proverb, "Love me love my dog," has its foundation in one of the deepest principles of human nature. But an urban dog-owner may perhaps be expected to acknowledge liability to pay for the cleansing rendered necessary by the habits of the favourite. A correspondent of the *Times* suggests that dogs may "easily be taught" to resort to the carriage way, instead of remaining upon the footpath. There are not many dog-owners, however, who possess the knack and the patience necessary for such education; and, even supposing it to be completed, an unfortunate constipated dog in a carriage way, endeavouring to detach an adherent foot or two of tapeworm from its person, would be an easy and certain prey to the swift butcher's cart or the passing automobile. There would soon be an outcry from urban dog-owners for the prohibition of wheeled vehicles. In the meanwhile, however, the tendency for reform seems to be in the opposite direction, for Dr. PARKES looks forward to the disappearance of horse-drawn conveyances as to the beginning of a new sanitary era. It is at least certain that the contributions of our equine friends towards the general defilement of town thoroughfares are very considerable, and that the withdrawal of these contributions would be an important step towards the simplification of the general problem. There would still remain the dogs, the cats, the garbage, the vegetable refuse, and the dust-cart. Worse than all, there would still remain the average town councillor, built upon the model of JOHNNY HEAD-IN-THE-AIR in Struwwelpeter, with his thoughts divided between schemes of electric lighting and a contemplation of his own importance, and so occupied by higher things as to have no consciousness of canine excreta until the happy day when he chanced to walk unwarily, and thus to introduce into the sanctuary of his own dwelling the nuisance which he had previously been content to ignore.

Annotations.

"Ne quid nimis."

THE PRACTICAL TEACHING OF MIDWIFERY IN AMERICA.

IN the *Journal of the American Medical Association* of Oct. 3rd, 1903, are published the results of 1000 cases of labour attended in the extern maternity department of the University College of Medicine, Virginia. The account is of considerable interest in that this is the first attempt to institute a system of free service for lying-in women in their own homes in the Southern States of America. It is also noteworthy for the very excellent results which have been obtained; the mortality rate is only 0·5 per cent., while only four cases of sepsis occurred. As the writer points out, such a mortality and morbidity rate contrast very favourably indeed with the results of both the intern and extern departments of some of the best known foreign maternities. They show what can be done even in the most unfavourable circumstances, many of these patients, including coloured as well as white women, being attended amidst surroundings of the utmost poverty, conditions even worse than those not uncommonly occurring in the extern maternity work of some of the London hospitals. Dr. J. F. Winn is to be congratulated on the results of his organisation and of his teaching. His aim has been to impress the students with the danger of infection and without using any great array of aseptic paraphernalia to reduce the system of disinfection to as simple a one as possible. Great care is taken in making vaginal examinations but the ante-partum vaginal douche is not employed. Special attention is devoted to keeping the hands and especially the examining hand sterile, and the disinfection of both the external genitalia and the hands is repeated before each examination. Vaseline is not employed as a lubricant. Reliance is placed upon the thorough scrubbing of the hands and forearms in soap and water, followed by their immersion in perchloride of mercury, 1 in 1000, for not less than five minutes and then in a solution of lysol of the strength of one drachm to the pint. Great stress is laid upon the proper management of the third stage of labour. The perusal of this report reminds us of the deficiencies in the practical training in midwifery of medical students in London. At the present time when the registration and training of the midwife are occupying the professional mind to such an extent the imperfect clinical training which medical students receive in this subject is in danger of being forgotten. The standard of the clinical teaching in midwifery, with the exception of that given in such an institution as the Rotunda Hospital in Dublin, is far below that received by the student in both medicine and surgery. The want of properly equipped lying-in hospitals throughout the country, the reluctance of women to enter such institutions, and the fact that most of the work must therefore be done in the homes of the poor render proper systematic clinical teaching almost an impossibility; indeed, in London midwives are better provided for in this respect than are medical students. It is almost impossible for the student who comes to London for the purpose of taking out special courses of study to obtain any opportunities of doing practical work in either midwifery or gynæcology. Even the amount of knowledge required of a student before taking duty in the extern maternity department of his own hospital is, we fear, in only too many instances very deficient. In most maternity departments the obstetric assistant is required to go with him to his first case of labour, but when, as not infrequently happens, this officer is engaged with some abnormal case the student often proceeds to his first case either alone or in the company of some friend who has completed his term of duty. It is true that the interests of the patient are safeguarded by his being required to send for assistance in all cases where he is in the least difficulty or doubt, but how much advantage can the student obtain from his term of office, completed as it so often is without his receiving any clinical instruction at all on the normal cases which he attends? Even if he meets with some abnormal case the teaching that he receives in the case is probably given to him by the obstetric assistant, often no doubt a very good man, but who is of the same standing as a house surgeon or house physician and whose teaching cannot for a moment be compared with the bedside teaching received by the student from the members of the hospital staff on medical and surgical cases. A system by which the student is dependent upon such casual and imperfect teaching in a subject of such practical importance as midwifery is obviously a wrong one. We fear, however, that no improvement will follow in this respect until the matter is taken in hand by the examining boards. It is one the importance of which is recognised by every obstetric teacher in the metropolis and it constitutes a grave defect in the training of the student which urgently demands a remedy. It is little wonder that foreign and colonial students express surprise when they are told that if they want systematic clinical teaching in midwifery they must go not to a hospital in London but to one in Dublin.

WATER-CRESS AS A SPECIFIC FOR BERI-BERI.

WE have received from the Foreign Office a copy of a despatch from Mr. John G. Haggard, His Majesty's Consul at Noumea, New Caledonia, relating to beri-beri, and a note on this despatch by Sir Patrick Manson, medical adviser to the department. The purport of Mr. Haggard's despatch is to report to the Foreign Office a circumstance respecting beri-beri which, to quote the guarded official language, "may or may not be of some importance in view of His Majesty's West African possessions." Beri-beri is very prevalent on the island of Noumea amongst the natives of all nationalities working at the mines and, says Mr. Haggard, "it seems to have been found out quite accidentally that watercress is an almost certain cure. Consequently all the mining companies are cultivating it largely." The despatch was submitted to Sir Patrick Manson who suggested, in reply, that the statement that water cress had been found to be a cure for beri-beri should be sent to THE LANCET, the *British Medical Journal*, and the *Journal of Tropical Medicine*, with an intimation as to its source. "I would point out," continues Sir Patrick Manson, "that similar statements as regards the influence of various kinds of food on beri-beri have frequently been brought forward on inadequate experience. It would seem that in the endemic areas many kinds of malnutrition predispose to the disease. It may be that there has been a deficiency of vegetables in the dietary at the mines in New Caledonia predisposing to beri-beri and that this deficiency has been made good by water-cress. That this vegetable has a specific action on the germ of the disease I question. However, it is an experience worth following up. The publicity given by the medical press will insure this." Sir Patrick Manson's inference as to the subordinate part that has been played by water-cress as a remedy for beri-beri is almost certainly right. On the other hand, it is conceivable that water-cress may have some specific action and we have certainly no right to exclude on *a priori* grounds such possibilities as these. The publicity given in our columns and in those of our contemporaries to Mr. Haggard's despatch will doubtless lead to a wide trial of the virtues of water-cress, so that in a short time we should have much recorded experience to guide us to a decision in the matter.

THE MENTAL AND MORAL EFFECTS OF THE SOUTH AFRICAN WAR ON THE BRITISH PEOPLE.

THE widespread and varied impression created on the people of Great Britain by the late war with the Boers of South Africa is a matter of common knowledge. In the *Journal of Mental Science* for January Dr. R. S. Stewart of the Glamorgan County Asylum makes an attempt to arrive at an exact idea of its effects on national character and conduct. "There is abundant evidence," says Dr. Stewart, "to show that it produced an immediate and very profound, though unlasting, modification of national character." The early period of the campaign, which comprised the last few months of 1899, was that of Britain's greatest stress. The events of that period included the siege of Kimberley, Mafeking, and Ladysmith, and the reverses sustained at Nicholson's Nek, Stormberg, Magersfontein, Colenso, and Spion Kop. The feelings engendered by the events of this period were those of painful anxiety, but a spirit of determination was aroused in the nation that at all hazards the enemy must be overcome and that no sacrifice should be felt to be too great for the purpose. During the last quarter, and especially in the last month, of the year 1899 there was a marked diminution of serious or indictable offences, but this improvement in the *morale* of the nation was not sustained, for in the following year the criminal tendency steadily rose to normal levels and in the last quarter of 1900 it showed an increase of 8·1 per cent. above that of average years for England. In Wales and Ireland similar phenomena were noticed. As regards offences against property a temporary subsidence of crime in this respect during the last quarter of 1899 was followed by a rise in the percentage of such offences during the first three quarters of 1900, while the increase in the last quarter was 9·7 per cent above the average. Similar conditions prevailed in Scotland and Wales. Crimes of impulse and passion, which had diminished appreciably in the last quarter of 1899, increased during the next year. "The year 1900," adds Dr. Stewart, "witnessed a gradual but steady weakening of the influences exerted by the events of the preceding quarter. The number of murders in England also increased slightly during 1900, the murders of newly born children, a peculiarly female crime, showing an increase of 6·1 per cent." As regards crime of a sexual nature a decrease in 1899 was followed by a return to normal levels before the closing of 1900 until in December, 1900, a great increase above normal limits was reached in all three divisions of the United Kingdom—viz., 28·9 per cent. in England, 60 per cent. in Ireland, and 61·1 per cent. in Scotland. Suicides and [illegible] to normal levels in 1900 and in December of that year an increase of suicides by 50 per cent. was noted in England. Combining the homicidal, suicidal, and sexual offences under one head as crimes of impulse and evil passion, says Dr. Stewart, the restraint produced in the last quarter of 1899 soon wore off and the percentage of crimes rose to considerable heights at the close of 1900. "The records relating to minor non-indictable offences indicated the same moralising effects as in the case of serious crimes [in 1899], an effect gradually but surely disappearing as time progressed, in 1900." The proportion of insanity has shown a grave tendency to increase, especially in the years 1901 and 1902, as regards "first admissions" to asylums of the United Kingdom. The marriage-rate showed a decrease during 1900 while illegitimate births showed a corresponding increase throughout the kingdom. There was thus for the time being, concludes Dr. Stewart, an improvement in the whole national *morale* during its period of trial—the last quarter of 1899 and the early days of 1900, a change the cause of which may be attributed to the circumstances of the time which were of such a nature as to arouse concern and even anxiety for the safety and success of the United Kingdom. Gradually, however, with the advent of success to the British arms in 1900, the effect produced by these events passed away until by the end of 1900 it had vanished and there was a return to something even worse than previously prevailing conditions. "We were rudely and painfully aroused out of our moral trypanosomiasis," concludes Dr. Stewart, "but to all appearance the danger being overpast, the reaction has proved, and is likely to prove in the future, productive of the gravest results."

PRESCRIPTION AND ADVICE.

THE relative values of a medical man's advice and of his prescription are very different in the public and in the professional eye. The public pin their faith to "medicine," the instructed know how often advice is the more valuable portion of a medical man's services. At the present time when controversy is raging round the advisability of precluding medical men from dispensing their own prescriptions it is interesting to notice how completely in older days the value of medicine outweighed the value of the medical adviser's attention in his patient's estimation. By the kindness of Dr. R. P. Smallwood of Little Waltham we have before us a "doctor's bill" of the year 1697. In this foot-and-a-half-long document no mention is made of any visit or consultation. All the fees demanded are for draughts and applications supplied to the patient. The prices for these appear to be high and it may be presumed that the discrepancy between the market value of the drugs and the amounts charged for them is balanced by the uncharged-for visits in connexion with the illness for which the prescriptions were written. Some of the items afford quaint reading by reason of the candid description of their powers contained in the titles of several of the favourite prescriptions in vogue at that date. "Purging potions" and "expulsive powders" figure largely in the list and whilst the nature of these is fairly indicated in their name we are less certain of the direction in which "elixir proprietatis" was intended to work. Apparently the patient of the seventeenth century was content to know the aims of his medicine, though he remained in ignorance of its ingredients. To-day the sophisticated invalid is satisfied with the exact names of the drugs employed, though in complete ignorance of their therapeutical action. His faith is pinned, so to speak, to the blessed word "Mesopotamia"; if he recognises in the prescription the name of the fashionable drug of the hour his confidence in the treatment prescribed is satisfactory. The account of which we are speaking amounted to £38 and our readers will be interested to hear that the patien objected that this was excessive. In the enlightened tim of to-day such objections, of course, never arise.

THE AMBIDEXTRAL CULTURE SOCIETY.

THE syllabus of the subjects to be brought before th Ambidextral Culture Society during the current sessio seems to give promise of some interesting papers and di cussions. On Feb. 10th the honorary secretary read paper on the Aims and Methods of the Society. The nex three announcements are: Ambidexterity in the Infan School, by Miss Margaret McMillan, on March 2nd Physiology of Simultaneous Ambidextral Work, by th honorary secretary, on March 16th; and two papers o Ambidexterity in Angling, by Captain Hart-Davis an Mr. R. B. Marston, on April 6th. On May 18 Dr. James Shaw will discourse on Ambidexterity fro the Medical Point of View. The meetings will b held at the rooms of the Medical Society, 11, Chando street, Cavendish-square, London, W., at 5 P.M. each day The lists of vice-presidents and committee contain numero names, including those of Lady Florence Dixie, Sir Jam Sawyer, Mr. E. Noble Smith, and the professors of natur history at the Universities of Edinburgh and St. Andrew The annual subscription seems to be very moderat The honorary secretary is Mr. John Jackson, F.E.I.S St. Dunstan's House, Fetter-lane, E.C. Our readers ma recollect that in the Huxley Memorial Lecture delivered the Anthropological Institute on Oct. 21st, 1902, Profess D. J. Cunningham, speaking on the subject of Righ Handedness and Left-Brainedness, said that man as far ba as we can trace was preferentially right-handed. A numb of letters on various aspects of the question subsequent appeared in our columns.

INTERNATIONAL CONGRESS ON TUBERCULOSI

BY a committee of organisation appointed for the purp it has been resolved to organise an international congre which is described as follows: "American Internation Congress on Tuberculosis, to be held October 3rd, 4th, an 5th, 1904, under the auspices of the Universal Expositio St. Louis, 1904, and of the American Congress on Tuberc losis." The present officers of the American Congress o Tuberculosis were, with few changes and exception elected to the corresponding offices in the American Inte national Congress. It was further resolved that the congre should be open to the legal, medical, and all other pr fessions, judges, philanthropists, men of science, statesme legislators, and all citizens interested in averting the ravag of the disease, and that they should be invited to coöpera and to become members of the body. Whilst wishing success to the proposed congress and fully acknowledgi the utility of the interchange of ideas between medical m of all nationalities, we are inclined to doubt the wisdom encouraging a lay element in discussions which parta purely of a technical character. The question of the pr vention of pulmonary tuberculosis is a vast one and membe of the medical profession are by no means unanimous as the manner in which prophylactic measures should be carri out. On the other hand, we have frequently laid stress on t importance of instructing the community at large as to th chief means by which infection may be reduced to minimum. We would venture, therefore, to suggest th there might be two classes of discussions, one purely tec nical to which only medical practitioners should be invite and the other of a more general character in which the la element might with advantage be encouraged. No goo could come of individuals joining in, or even listening t a discussion on vexed questions in connexion with th etiology of tuberculosis but misconceptions might very like arise. Whatever steps may ultimately be decided upon in the "fight against consumption," we strongly insist that the opinion of medical men must be paramount and that suggestions arising from those not trained in medical knowledge can only be considered of secondary importance.

THE AUTO-CAR AS AN AMBULANCE.

IN the opinion of Regimental Surgeon Prévost (*Archives Médicales Belges*) the ambulance of the future will be an auto-car. Over ordinary horse-drawn wagons these cars possess many and great advantages. In the first place, the length of a sick convoy will be diminished by a third, if not a half, and it will travel at a considerably greater speed. Secondly, the occupants of an auto-car ambulance will be spared the jolting and shaking inseparable from horse- or mule drawn vehicles when starting or halting, as well as those due to restive animals. Thirdly, the provision and carriage of bulky forage will be dispensed with. Against the auto-car can only be urged its cost and liability to go out of order. In a short time both these defects will, it is confidently anticipated, be reduced to a minimum. Another advantage in addition to those enumerated above would consist in the greater cleanliness of the auto car. The dejections of horses and other animals are a fruitful source of complaint if not of disease. It has been calculated by Surgeon Prévost that if auto-car ambulances were to be used exclusively for military hospitals it would be possible to economise 193 men per army corps.

THE CAMBRIDGE DIPLOMA IN TROPICAL MEDICINE.

IN November of last year the special board for medicine of the University of Cambridge presented a report to the Senate upon a proposal, which had been for some months under consideration, to establish in the University an examination and diploma in tropical medicine and hygiene. The report emphasised the need of greater facilities for the study of tropical diseases and their prevention and the desirability of encouraging practitioners who propose to practise abroad to give special attention to the study—a desirability already recognised in other countries. "In Germany and France," says the report, "military, naval, and colonial physicians are now required to attend courses in tropical medicine before taking up the duties to which they are assigned. There are also indications that similar requirements may ere long be enforced as regards medical men desiring to enter the British service abroad. At the present time candidates possessing the diploma in public health are preferred for appointments under the Colonial Office and efforts are being made by the army authorities to insure that military medical officers may be able to acquire the special knowledge and skill implied by the possession of this diploma. Similar considerations apply also to the case of duly qualified medical men who desire to engage in missionary work or to accompany exploring expeditions abroad. The course of study, however, which is appropriate for medical officers of health is far from including all that is necessary for a practitioner in the tropics, while it naturally includes much that has no special relevance to the duties and needs of the latter. In a recent Colonial Office circular it is accordingly proposed that all medical men whose fees are paid by Colonial Governments shall, before proceeding to their appointments, be required to pass an examination or to obtain a certificate of proficiency in tropical medicine. It therefore seems likely that an examination specially designed to meet the new requirements would not only obtain speedy recognition but would also prove of service to students of the subject by establishing a satisfactory standard of attainments and by marking out the proper lines of study. The University already provides facilities for the study of various branches of the subject and these facilities could without much difficulty be extended." The special board for medicine having addressed Mr. Chamberlain and Mr. Brodrick, received from both gentlemen direct encouragement of the idea that the University of Cambridge should institute a test in the knowledge of tropical diseases and hygiene and accordingly came to the conclusion that the University would be performing a public service by adopting the proposal under consideration. The board conferred with the State medicine syndicate and ascertained that that body approved the proposal and was prepared to undertake the management of the scheme and the conduct of the examination and its report was approved by the Senate on Jan. 28th last. The regulations for the examination in tropical medicine and hygiene are very simple. The examination will be held once in the year and any person whose name is on the Medical Register will be admissible as a candidate if a period of not less than 12 months has elapsed between his attainment of a registrable qualification and his admission to the examination. The subjects of the examination will be the nature, incidence, prevention, and treatment of epidemic and other diseases prevalent in tropical countries, and as evidence of study and attainments a candidate may present any record of work done in the field indicated and any diploma of public health or sanitary science Such evidence will be considered by the State medicine syndicate as a qualification for admission to the examination and will also count in the examination. *The examination will comprise the following* subjects .—

[illegible] thological and bacteriological investigation.
[illegible] nd life-
[illegible] emical
[illegible]
[illegible] ntion,
[illegible] c, and
[illegible] kwater
fever. trypanosomiasis; relapsing fever; dengue; yellow fever; plague;
[illegible]
animals and by poisoned weapons; sunstroke.

3 The general effects on health in the tropics of seasons and climate. soil, water, and food. Personal hygiene, acclimatisation. *Principles* of general hygiene, with special reference to food- and water supplies, sites, dwellings, drainage, and the disposal of refuse. The sanitation of native quarters, camps, plantations. factories, hospitals, asylums, jails, pilgrim and coolie ships. Principles and methods of disinfection

Every candidate will be required to pay a fee of six guineas before admission or readmission to the examination. We regard the innovation of the University of Cambridge as one of the highest importance.

THE REVACCINATION BILL, 1904.

THE Revaccination Bill is down for discussion in the House of Commons on April 26th. It is of importance that everyone who wishes to rid the country of small-pox epidemics should do his best at this moment to strengthen public opinion in support of systematic revaccination at school age. The Imperial Vaccination League is distributing copies of a manifesto in favour of revaccination and it is hoped that it will be signed by a very large number of leaders of thought and of social and industrial influence. Medical practitioners will do most useful public work if they will bring this manifesto (of which copies can be had gratis on application to the Secretary, Imperial Vaccination League, 53, Berners-street, London, W.) under the notice of the municipal authorities in their own locality, of ministers of all denominations, of manufacturers, hotel-keepers, tradesmen, and all large employers of labour and will ask them to sign it. The economic loss which results from every epidemic of small-pox is enormous, as is also the cost of keeping up immense small-pox hospitals. Everyone pays rates and all the expenditure on small-pox comes eventually out of the rates. It is therefore everyone's interest to put an end to epidemics of small-pox. The manifesto, which has already several hundreds of important signatures, runs thus :—

> Believing that in vaccination and revaccination we possess the best protection against epidemic small pox, I should heartily welcome legislation making revaccination at school age obligatory on all but the children of conscientious objectors or those who may be for a time excused on the ground of ill-health.

THE HEALTH OF SIR SAMUEL WILKS.

The many friends of Sir Samuel Wilks will be glad to hear that he is progressing favourably towards recovery from an acute attack of appendicitis which developed on Feb. 5th. Within seven days his condition became so critical that Mr. C. J. Symonds was called in to operate. He opened an abscess and removed the appendix which contained a large concretion and was gangrenous for the space of one inch from its distal extremity. At the commencement of the attack Sir Samuel Wilks was seen by Mr. W. Boulting who summoned Dr. P. H. Pye-Smith. The initial symptoms of the case might have been considered due to renal colic but the appearance in the right iliac region of a tumour which began to get bigger at an appreciable rate cleared up the diagnosis. We are glad to announce that Sir Samuel Wilks is now progressing satisfactorily and it is considered that all danger is over, one feature in the state of the patient especially pointing to a favourable issue being the steady improvement in his general condition for the last four days.

THE TRAINING OF MIDWIFERY NURSES IN IRELAND AND THE REGULATIONS OF THE CENTRAL MIDWIVES BOARD.

In an annotation last week (p. 449) we referred to a correspondence between Mr. E. H. Tweedy (Master of the Rotunda Hospital, Dublin) and the secretary of the Central Midwives Board in reference to the two regulations that candidates "must have attended and watched the progress of not less than 20 labours and personally delivered the patient, and, further, must have nursed 20 lying-in women during the ten days following labour." Owing to these two rules nurses trained at the Rotunda Hospital, Dublin, are precluded from qualifying for admission as candidates to the examinations of the Board. We understand that at the request of his colleagues Dr. J. W. Byers, professor of midwifery, Queen's College, Belfast, wrote to the chairman of the Central Midwives Board pointing out that these two regulations would also disqualify midwives trained in the Maternity Hospital, Belfast (where the nurses reside for a period of six months and where they have a similar course of instruction to that of the Rotunda Hospital and are granted a certificate on passing an examination at the end of their training). A reply has been sent to Professor Byers of the same import as that received by the Master of the Rotunda Hospital, that "they [the Central Midwives Board] regret that the suggested alternatives were not brought to their notice before the rules were sent to the Privy Council, as having been now approved by that body it is impossible for the Board to alter them." As a result of these regulations a permanent disqualification is made of midwifery nurses trained not only in Dublin but in Belfast and the rest of Ireland. According to the rules of the Central Midwives Board the certificates as to personal conduction of 20 labour cases and the attendance of a ten days' puerperium are to be signed by a registered medical practitioner or by the chief midwife or matron of an institution recognised by the Board, or in the case of a Poor-law institution by the matron, being a midwife certified under the Midwives Act, or a superintendent nurse certified in like manner and appointed under the Nursing in Workhouses Order, 1897, and attached to such an institution, or by a midwife certified under the Midwives Act and approved by the Board for the purpose. Surely the certificate of the Rotunda Hospital, Dublin, or of the Maternity Hospital, Belfast, is equal to any of these. Further, as everyone knows, it is a common occurrence for a run of 20 normal midwifery cases to occur in succession and so a midwife might actually be able to fulfil the conditions necessary for going on to the examination of the Central Midwives Board and never have been brought in contact with, or recognised, or seen properly managed, such a complication of labour as hæmorrhage or eclampsia. A woman who has resided six months in an Irish maternity hospital would never be in such a position of ignorance. No body has done more to raise the standard of obstetric medicine than the Royal University of Ireland and here is the regulation of the Senate for students on the question of practical midwifery :—

> Attendance for a period of six months at a recognised midwifery hospital, containing not less than 15 beds in regular occupation where clinical instruction in midwifery and diseases of women and children is given, or for six months at a midwifery dispensary recognised by the Senate, where similar clinical instruction is given. During this period the candidate is required to attend at least *twenty* labours, of *ten* of which at least he must have had personal charge.

Nothing is here said as to length of attendance during the puerperium and only *ten* cases of *personal* conduction are required, but, on the other hand, a six months' course is specified either at a lying-in hospital or at a midwifery dispensary. Why should the Central Midwives Board adopt a different course in reference to its requirements from pupil midwives? Is what is required from students not enough for midwives? The answer of the Central Midwives Board to those who have protested against these regulations as unfair and as really not giving a guarantee that those fulfilling them have necessarily received a requisite training is, in fact, no reply at all. It simply begs the question and it also (by regretting that the suggested alterations were not brought to its notice before the rules were sent to the Privy Council) admits the justice and fairness of these objections to its rules. To say that it is impossible to alter rules approved by the Privy Council is no argument; the Board might surely ask the Privy Council to change regulations which further experience has shown to be inexpedient.

YOGA AND HYPNOTISM.

The practice of yoga, or mystical self-discipline, is common all over India and is undisguisedly advocated by American occultists and, more mysteriously, by their English imitators. From the point of view of scientific psychology the practice is simply a quaint means of inducing the hypnotic state and as such deserves the study of all those medical men who number among their patients hysterical believers in the doctrines of the late Madame Blavatsky. The effect of practising yoga must be at least bad for the nerves and injurious to the still unborn descendants of its practitioners. As described in the Brahmavâdin it consists at present of four species—Mantra-, Laya-, Râja-, and Hatha-yoga. A pious person, possibly an Eddyite, follows Mantra-yoga by repeatedly pronouncing some word and concentrating all his mind upon it. In Laya-yoga all the thoughts are concentrated on one thing or the idea of it, so that we become mystically one with it. Râja-yoga consists in holding the breath and consequently, as the Hindu yogis believe, in controlling the mind. Hatha-yoga is even more frankly hypnotic and its object—concentration—is obtained by sitting for hours in a cramped attitude or simply by squinting. The cramped attitudes of Indian yogis, which are maintained by some during a lifetime, have become proverbial. In a different spirit and in a more graceful manner artists' models may be described as unconscious followers of Hatha-yoga. Trilby was such and her creator, Du Maurier, had much to say on the subject of mesmerism as induced by posing in one attitude in an artist's studio. Squinting with determination at the tip of the nose is a method much recommended by the yogis who doubtless see nothing comic in the act. But they practise other similar contrivances. The great aim is to hypnotise. Thus English followers of neo-Buddhism have told us that they are in the habit of clearing the mind as far as possible of all ideas or thoughts. Among beginners this is attempted on a fasting stomach for about five minutes before breakfast. It must be an easier process for adepts than for the laity who at most, unlike the little girl in *Punch*, usually think not so much of "nothing" as of "things to think about."

COMPLIMENTARY DINNER TO MR. TIMOTHY HOLMES.

THE dinner to commemorate Mr. Holmes's retirement after a long period of service as surgeon, and later as treasurer, to St. George's Hospital was attended by a large number of his former colleagues and pupils. Among other distinguished friends besides the staff of the hospital were present the Regius Professor of Medicine at Cambridge (Dr. T. Clifford Allbutt), the Regius Professor of Surgery at Cambridge (Mr. Howard Marsh), and Sir Thomas Smith. The Earl of Cork and Orrery, who presided, proposed Mr. Holmes's health in a speech which recounted the many valuable efforts that he had made in behalf of surgery generally and of St. George's Hospital in particular. Dr. W. Howship Dickinson and Mr. J. Warrington Haward followed with excellent laudatory speeches and Mr. West, deputy treasurer to the hospital, read a long list of those who had sent letters of regret at their inability to be present. Mr. Holmes made a sincere and eloquent reply and after the presentation of an album containing the signatures of all the diners the evening, which had been enlivened also by some capital singing, terminated with a vote of thanks to the chairman.

THE TRIUMPHS OF SYNTHESIS.

ONE by one certain valuable commercial products are yielding to the analytical observations of the chemist and some day, perhaps, the world may be independent of nature's slow synthetic processes. Not a few people, however, confess to a prejudice in regard to synthetic products and to a preference for the natural article. There would appear to be either some quality missing in the synthetic preparation or else an additional quality which is undesirable; somehow or other it is not exactly the same in its effects it may be or in its appearance or properties. Perhaps there is an element of suggestion or fancy in this matter but for choice we are certain that many would decide in favour of natural indigo for dyeing purposes rather than the synthetic substance, and would prefer the real natural perfume of the flower rather than the synthetic oil, chemically and physically identical though they may be. Certainly in the case of a few substances possessing æsthetic qualities the synthetic product does not appear to give the same gratification. Man may discover how to build the molecular structure but all the same there would appear to be missing something in the architectural *tout ensemble* as nature presents it to us. The natural product may not be so pure but in this very possibility may rest the dignity, beauty, and completeness of the natural structure. Æsthetic qualities, however, do not count for much in the case of more or less coarse goods which answer broadly the purpose of the natural article. Thus could indiarubber be synthesised so successfully as to have the properties of natural rubber no one would doubt that a very useful addition to the necessities of modern life would be made. Indeed, the synthesis of rubber would count amongst the greatest triumphs of chemical science in its application to the elaboration of substances which hitherto have been nature's exclusive production. Amongst the latest synthetic achievements of moment is that of camphor which, it is announced, is now being produced on a commercial scale by a comparatively simple process from turpentine. Turpentine oil is heated with oxalic acid, an oxalate being formed with pinene, the principal constituent of turpentine oil. The oxalic acid effects a further change with the production of a formate which when heated with alkalies yields camphor and carbon monoxide and water. The camphor so made is afterwards sublimed and it condenses in the form of snow-white crystals. It will be interesting to see what effect this synthetic process will have upon the supply of the natural camphor from Japan and, further, whether it will compensate for the reduced output which the war between that nation and Russia must inevitably occasion. Science seems to have anticipated this contingency.

THE HÆMOSTATIC CONSTITUENT OF THE SUPRARENAL GLAND.

AT a meeting of the Chemical Society held on Feb. 4th Dr. H. A. D. Jowett brought forward the results of his investigations on the chemical nature of the hæmostatic constituent of the suprarenal gland. The work of inquiry was conducted in the Wellcome chemical research laboratories. Previous investigators, and notably the Japanese chemist Takamine, had been able to prepare a crystalline substance from these glands which produced an enormous rise in the blood pressure when injected intravenously. The names proposed for this substance were at first "epinephrine," then "suprarenine," and last by Takamine "adrenaline." Apparently investigations have shown that all three are more or less pure forms of the same constituent and Dr. Jowett has demonstrated that it is probably a catechol derivative with, perhaps, a pyrrol nucleus. The formula now assigned to it is $C_9H_{13}O_3N$. On fusing with potash a substance was obtained giving the protocatechuic acid reaction. Further, it yields trimethylamine and veratric acid when completely methylated and the resulting product oxidised. According to the constitution ascribed to epinephrine it would seem to show an analogy with muscarine and it is significant that amanitine, a fungoid base related to neurine, yields muscarine on decomposition with nitric acid and evolves trimethylamine on heating, which is also yielded by epinephrine, and the constitution altogether is not widely different from the suprarenal principle, assuming Dr. Jowett's view of it to be correct.

THE GEOGRAPHICAL DISTRIBUTION OF INSANITY IN THE UNITED STATES OF AMERICA.

AN interesting report recently issued by Dr. W. O. White of the Government Hospital for the Insane at Washington, D C., gives a lengthy account of the geographical distribution of insanity in the United States and its significance. He finds that the proportion of insanity "is highest where there is greatest congestion of population and therefore where the stresses incident to active competition are most severe." This view is generally accepted by alienists in America. While hereditary predisposition is recognised as a leading cause of insanity he believes that a quiet life is a guarantee against mental breakdown as regards some of its forms. On the other hand, the stresses of excessive study, business anxiety, loss of property, domestic calamity, excitement in love, and politics are found to be definite exciting causes of insanity. The tendency to insanity is strong in those who from constitutional predisposition indulge in alcohol for long periods of time. Alcoholic insanity prevails most frequently in crowded industrial centres of population "where the struggle for income is bitterest." Regarding ethnical conditions the interesting fact is recorded that among the North American Indians insanity is of rare occurrence. This is not because these tribes are exempt from the diseases or the vices of civilisation but because they live an easy-going outdoor life free from care and worry for the future and therefore free from mental overstrain. The negro, says Dr. White, remains sane despite his unhygienic surroundings so long as he remains in the country, his natural home. But when he goes into the Northern States and cities and enters into active competition with the white who is mentally his superior he soon succumbs in the struggle. Thus in Georgia, where the greatest number of negroes are found, there was a ratio of 1 insane negro to 1764 of the coloured population, while in New York the ratio was 1 to 330 or almost exactly the same as for the white population. In Alabama, Arkansas, Kentucky, Missouri, North and South Carolina, Texas, and Virginia the ratio of insanity among negroes is 1 to 1277 as compared with 1 to 450 for the white population. In the industrial States of the East insanity is very common, the ratio being, for example, 1 to 348 of the general population in Massachusetts. These facts, says Dr. White, though in the main well established, are of interest in showing the ill-effects of mental and physical stress in combination with advanced civilisation operating in great cities and centres of population. Dr. White also refers to the question of miscegenation as tending to increase the vulnerability of the coloured races to tabes dorsalis, general paralysis, and other mental and cerebral diseases, a point to which attention was recently drawn in THE LANCET.[1]

THE AUTOMOBILE SHOW AT THE CRYSTAL PALACE.

THE official show of the Society of Motor Manufacturers and Traders, which opened at the Crystal Palace on Feb. 12th, will remain open until Wednesday, the 24th, and is a remarkable tribute to the energy of the British manufacturer. It is well worthy of a visit by all who are interested in automobilism. Although the show is not confined to the productions of our own country—our foreign competitors being well represented—yet the "all-British" manufactures are assuredly seen to better advantage than on any previous occasion in the history of the motor industry. It is, perhaps, from a national point of view a little disconcerting to learn from the latest return to the Board of Trade that we imported last year no less than £2,000,000 worth of cars and parts and exported only £344,025 worth. To judge, however, from the signs of progress on the part of our home manufacturers which are everywhere in evidence at the Crystal Palace this slight to our national pride will soon be righted. The present show embraces motor vehicles of every description—from the humble motor cycle to the colossal motor omnibus and brewer's dray, with an *omnium gatherum* of the usual "runabouts," broughams, and the more or less luxurious pleasure vehicles. Certainly for the man of means there is no end to the beautifully designed and finished cars, ranging in cost from 500 to over 1000 guineas each; for the man of moderate means there is a still greater though less *recherché* choice; whilst for the man of modest means the prediction that the season of 1904 would see him well catered for is amply fulfilled. It is not within our province to suggest or to recommend individual cars or manufacturers, as obviously the circumstances of varying needs and pecuniary considerations must be important factors in guiding the choice of a vehicle. A visit to the Crystal Palace, however, before the exhibition closes will be an invaluable object-lesson to the intending motorist and also an opportunity to see under one roof what is admitted to be the finest display of automobiles yet held in this country.

MUSCLE AND NERVE RAYS.

THERE would appear to be no longer any doubt that rays are given off by active muscle and nerves, for the observations made by M. Charpentier have been completely confirmed by Dr. Hugh Walsham and Mr. Leslie Miller, who have sent us a communication upon the subject. These gentlemen point out that experiments are remarkably easy to perform and are absolutely convincing as to the actual existence of the rays. These emanations from the human body and their effect upon a fluorescent screen were first observed by M. Charpentier while studying Blondlot's rays (the so called "n" rays). When certain conditions are observed there is no difficulty in obtaining confirmation of M. Charpentier's observations and the most satisfactory procedure is as follows. The screens are prepared with hexagonal zinc blende which is placed in the form of a very thin film on thin paper, gold-beater's skin, or thin celluloid. The screen is excited by exposing it to the ultra-violet rays, sunlight, or, better still, magnesium light. The fluorescent light of the screen is then allowed to die away until it has reached the steady stage. At this point if a muscle in a state of contraction, as, for example, the contracting abductor and adductor pollicis of the thumb, be placed underneath the fluorescent screen it will be seen to brighten perceptibly. We have inspected photographic plates which demonstrate this intensifying effect of muscle and nerve rays upon the fluorescence of the screen.

BENZENE, A POISONOUS CONSTITUENT OF COAL GAS.

ALTHOUGH benzene would appear to play no part in the poisonous effects of coal gas on man, yet this substance has a very interesting physiological action which indicates the possibility of giving rise to toxic symptoms. In a paper read at a recent meeting of the Royal Society Dr. R. Staehelin presented the results of an investigation of the action of coal gas upon frogs, in which it was shown that when frogs are exposed to coal gas motor phenomena are produced which are absent if the coal gas is previously purified by passage through oil and that these phenomena can be reproduced if the purified gas is made to take up benzene vapour. The investigation had its origin in a recent paper by Vahlen in which it was maintained that a difference exists between the poisonous action of coal gas and of carbon monoxide, and, in the case of frogs at any rate, the conclusion seems now to be that the differences between the effects of carbon monoxide and of coal gas depend on the presence in the latter of benzene. Vahlen stated that warm-blooded animals and frogs die more rapidly in coal gas than would be expected from its percentage of carbon monoxide and also that frogs placed in coal gas present excitatory phenomena which are absent in pure carbon monoxide. In warm-blooded animals the conditions are quite different, experiments showing that air containing a small percentage of benzene had no effects on a guinea-pig, nor was any success obtained in producing either acute or chronic poisonous effects by administering benzene to a rabbit by inhalation It is suggested that in the case of man the minute quantities which are absorbed by the lungs are rapidly oxidised and excreted as an aromatic sulphate. According to this there would be no reason for supposing that the poisonous effect of coal gas on mammals is determined by anything except the carbon monoxide which it contains. Mr. A. Wynter Blyth, however, in his work on poisons, states that from certain sources of information it is evident that the vapour of benzene has a distinctly narcotic effect while influencing also in a marked degree the spinal cord, the characteristic symptoms being noises in the head, convulsive trembling, twitching of the muscles, and difficulty of breathing.

[1] THE LANCET, Nov. 7th, 1903, p. 1314.

THE NETTLESHIP PRIZE FUND.

To commemorate his work in ophthalmic surgery a gold medal has been established by the friends and pupils of Mr. E. Nettleship, to be awarded periodically for work done in ophthalmology. At its last meeting the medal was handed over to the custody of the Ophthalmological Society of the United Kingdom by Sir Thomas Barlow, representing the subscribers to the fund.

THE SANDGATE SCANDAL.

THE report of the medical officer of health of Sandgate will not fail, we hope, to attract the attention of the Local Government Board. Sandgate has a population of 1955 inhabitants and consists practically of a long street built by the sea shore. It should be one of the healthiest places in England, but there were last year no less than 64 deaths The birth-rate is equal to 18·9 per 1000, there being in all 37 births. These extraordinary figures find their explanation within the walls of those so-called sanatoriums which were fully described in these columns and which are run as a money-making business by the too notorious Mr. J. J. Jones.[1] Among the general population of Sandgate the deaths amounted to only 7·1 per 1000, for no less than 50 out of the 64 deaths occurred in the institutions or convalescent homes that abound at Sandgate. Of these, 45 deaths were due to pulmonary tuberculosis, and 43 out of the 45 took place in Jones's homes or "sanitoria." At the Bevan Home 1600 patients have been received during the course of the year and only 16 of these were suffering from pulmonary tuberculosis; one died. But in the Jones's homes no less than 881 patients were suffering from this disease and, as already stated, 43 of them died. Here, then, we have a total of 897 tuberculous patients set down in the midst of a population of 1955 persons, and this in the course of a single year. It must be borne in mind, as we fully explained in our account of Jones's homes, that these are not situated in the outskirts and in the open country but in the very centre and most crowded parts of the town. Further, these patients are not placed under the care of a medical board but the sovereign master and organiser of these homes is a layman who has taken this up as a matter of business and is just as ready to contract for burying the dead as for nursing the living, so long as a profit can be made out of the transaction. Should such trading as this be allowed? Can we afford to sanction such speculation in human misery, and, if so, should it be permitted to continue in the midst of a town? Unwholesome industries are not allowed in towns. Is it a wholesome industry to receive and to crowd together and to make a profit out of 881 persons suffering from pulmonary tuberculosis?

THE medical officer of health of the Cape Colony states that for the week ending Jan. 23rd no case of plague occurred throughout the colony. Plague-infected rats were found at Port Elizabeth and East London, and "one rodent, probably plague infected," was found at Knysna. Of 369 rats examined during the week in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the acting Governor, received at the Colonial Office on Feb. 12th, states that for the week ending Feb. 11th there were four cases of plague and three deaths from the disease.

THE French National Congress of Gynæcology, Obstetrics, and Pediatrics will take place at Rouen in April. The sittings will begin on Tuesday, the 5th, and terminate on Sunday, the 10th. The secretary of the Congress is Dr. Albert Martin, 6, Place de la Cathédrale, who will be glad to furnish any other information which may be desired.

A MEETING of the Faculty of Medicine of the University of London will be held at the University Buildings, South Kensington, at 5 P.M., to day (Friday), for the purpose of receiving a communication from His Majesty the King concerning the proposed Institute of Medical Sciences.

A GRAND festival dinner will be held to celebrate the centenary of the Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City-road, E.C., in the Grand Hall of the Hotel Cecil on Friday, April 22nd.

"The Medical Aspect of Motoring" is the title of a paper which is to be read at a meeting of the Western Section of the Scottish Automobile Club in Glasgow on March 7th by Professor Hugh Galt, M.B., C.M. Glasg.

THE LONDON COUNTY COUNCIL: THE MIDWIVES ACT, 1902.

AT the usual weekly meeting of the London County Council held at Spring-gardens on Feb. 9th, Lord MONKSWELL, the chairman, presiding, the general purposes committee brought up a report as to the administration of the Act, the powers under which the Council in December last decided to exercise. The general purposes committee having conferred with the public health and public control committees, recommended that to the order of reference to the public health committee should be added for consideration and report all questions relating to the Act.

Mr. E. A. CORNWALL (vice-chairman of the Council and chairman of the general purposes committee) moved the reception of the report.

Mr. R. MELVILL BEACHCROFT (Paddington North) regretted that the general purposes committee had not considered one matter which was very important in connexion with the administration of the Act and that was whether or not the Council meant to exercise the power that the Act gave to add to the committee people from outside who were versed in the wants of the poorer parts of London, especially women. He doubted whether many members of the Council knew what a very important influence this action might have on future generations of Londoners. The report presented to the committee by the officials of the Council, he believed, indicated that some such action as was here hinted at should take place. He suggested the addition to the recommendation of the committee of the following words: "With instructions to report forthwith whether the Council should be advised to avail themselves of the provisions of the Act which enable them to add to the committee persons, especially women, conversant with the needs of the poor."

Sir HENRY BLISS (Holborn) seconded the amendment.

Mr. CORNWALL was sorry he was not able on behalf of the general purposes committee to accept the amendment. The committee had before it a report which set out that the Council had the power to co-opt members on a special committee for the purpose of carrying out its duties under the Midwives Act, but the public health committee and the general purposes committee after consideration came to the conclusion that it would be undesirable for the Council to adopt such a course as that. On the other hand, they were of opinion that it would be much better to place the administration of the Act, so far as the Council was concerned, in the hands of the public health committee. He did not think the Council was at all likely to agree with the idea or generally to agree with the views of Mr. Beachcroft that they strengthened a committee by adding outside representatives. They must remember that under this Act there was a Central Midwives Board and the Council had not such large and extensive duties as would necessitate the bringing in of outside people. There were councils in the different parts of the country where it might apply with some force, but in the county of London, as they had done under the Infant Life Protection Act and the Shop Hours Act, they should not depart from their settled policy.

---

[1] See THE LANCET, August 22nd, 1903, p. 565.

Mr. RUSSELL SPOKES (Walworth) thought that even on the Council itself they might be greatly assisted in many portions of their work by having women members. On boards of guardians and other bodies he had seen good, useful work done by women and this was one instance where he believed it would be exceedingly advantageous if they had women members of the Council. It was not the fault of the Council that they could not have women directly elected to their body. If they could there would be a large majority of members of the Council who would willingly vote for women being enabled to sit as councillors or aldermen Under the Midwives Act they had power to appoint women and he considered that it should be left to the Council to decide and that they should not content themselves with the adoption of the report of the general purposes committee. The majority of the Council had resolved against co-opting outside and non-elected representatives on their committees, but where they had the opportunity, as under this Act, he thought they should take advantage of their powers and co-opt women exactly in the same way as they decided a few weeks ago that it would be desirable to co opt women on the Technical Education Board. He hoped the Council would not stultify itself and go back on that decision in regard to a matter which so very nearly pertained to the women of the county.

Dr. J. FLETCHER LITTLE (Marylebone East) regarded it as one of the most serious defects of the London County Council that women were excluded from membership and he supported the appointment of women on this committee. There was a great deal of work that women could do very much better than men and the question would continue to come up until it was settled that they might have women elected to the Council.

Lieutenant Colonel ROTTON (Clapham) remarked that if ever there was a committee where the desirability of co-opting women existed it was undoubtedly this one Fortunately they had a number of medical men on the Council, but the majority of the members were incapable of arriving at a satisfactory decision in regard to certain delicate points which would have to be settled by this committee. He therefore hoped that they would take advantage of the powers conferred upon them by the Act and co-opt a number of women.

Sir WILLIAM J. COLLINS (St. Pancras West) was in favour of women being eligible for election to the Council and if that measure were adopted they would naturally find their places on the appropriate committee where he was sure they would render valuable assistance to London. In regard to the particular question before them it was hardly desirable to carry the amendment in view of the fact that if the public health committee found it necessary to call women to their assistance no doubt it would bring up a recommendation to that effect at the Council. Not only would the amendment add women to the public health committee for this particular purpose but it would complicate the whole way the committees of the Council were worked. He was sure the chairman of the public health committee would be able to get any expert assistance, either male or female, to make this Act a success.

Mr. G. H. RADFORD (Islington West) said that if Mr. Beachcroft would alter his amendment so that the power of co-option should be limited to women he thought he would find a large measure of support on the Council. He desired, however, to distinguish between this Act and the Education Act because in appointing women under the Education Act they acted under *force majeure;* they were required by law to appoint them. They were not so required here but they would do wisely if they did so.

Mr. G. J. COOPER (Bermondsey) (chairman of the public health committee) said that the matter had been before his committee and they were unable to see their way to suggest that women should be added to the committee When the committee had the opportunity of considering what should be done and how the Act should be administered it was quite possible that they would bring up to the Council a motion directly dealing with the subject and this would enable Mr. Beachcroft to have a distinct vote—yea or nay. It was purely a question of administration He knew there were members of the committee who were very sympathetic, who had not the slighest hostility to women helping the administration of the Midwives Act, but how it was to be done must rest with the committee. The committee would consider it and bring up a report on the whole question which would give the Council an opportunity of coming to some definite decision upon it.

On a show of hands there voted: for the amendment, 32; against, 27; majority for the amendment, 5.

The recommendation of the committee, with the addition proposed by Mr. Beachcroft, was then put as a substantive motion and unanimously adopted.

Looking Back.

2. Two dorsal vertebræ anchylosed.
3. A lumbar vertebra, affected with caries.
4. Several lower jaw bones in a state of caries.
5. A radius, covered with exostoses; in short, examples of all the ordinary forms of disease which attack bone. So that the bears, at least, of an antediluvian world, would seem to have suffered from necrosis, inflammation of the bones, toothache, ending in caries of the alveolar processes, and diseases of the joints, followed by anchylosis, and doubtless, if their bones suffered, their soft parts did not escape. Dulce est socios habuisse malorum. We suppose, at intervals, that we discover hitherto unendured maladies; but nature, even in departing from her beneficence, appears to be governed by invariable laws. Here we have evidence of the same diseases that now occur, having afflicted the beings of creation which existed many thousand years ago, which probably inhabited the earth before man had asserted his supremacy.

HOSPITAL REPORTS.

GUY'S HOSPITAL.

*Contagious nature of Erysipelas?**

A female, labouring under ascites, had been for some time under the care of Dr. Bright, in Charity Ward, when, on February 1st, the operation of paracentesis abdominis was performed; a severe attack of erysipelas ensued, which, occurring in a constitution previously broken up by disease, proved fatal on the third day. A young woman is in the same ward under the care of Mr. Bransby Cooper, with an ulcer of the leg; her general health remarkably good. Being of the same religious persuasion as the poor woman who died, (namely Catholic,) she rushed from her bed, and in her "last moments" hung over and clasped the body of the dying patient. On the same morning this young woman sickened; she [illegible] w[illegible] and nausea, and on the following [illegible] erysipelatous inflammation [illegible] on [illegible] is [illegible] extending up [illegible] have run very high, [illegible] fatal.

TESTS OF CERTAIN OPEN DOMESTIC GRATES.

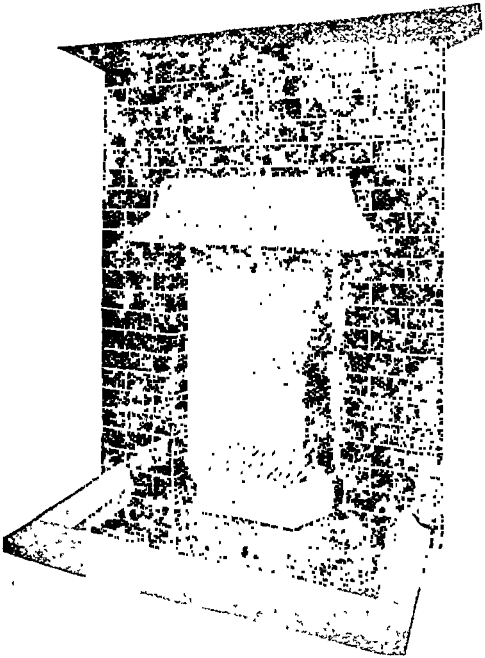
REPORT BY THE COAL SMOKE ABATEMENT SOCIETY.

IN the summer of the year 1901 a series of tests was made under the supervision of the Coal Smoke Abatement Society on six domestic open grates. The results, which were published in THE LANCET of May 10th, 1902, p. 1342, and afterwards in a special report, clearly demonstrated that there is a remarkable difference in effectiveness and economy between the numerous types of grates which are claimed to be "smokeless," "smoke consuming," or "smoke preventing." It was further shown that it is quite possible to produce a grate combining heating power and economy of fuel with a comparative freedom from emission of smoke so frequently associated with the use of ordinary household coal.

Since this series of tests was made the society has been on different occasions requested to investigate the claims of other grates, but until recently no opportunity of doing so recurred. In the winter of 1902-03, however, an exhibition of grates and other matters was held at the Crystal Palace and the society offered a prize or certificates in respect of such open grates burning ordinary bituminous coal as should in the opinion of a jury show substantial absence of smoke effectiveness of heat production and economy of fuel, in addition to the usual qualifications of a sitting-room grate.

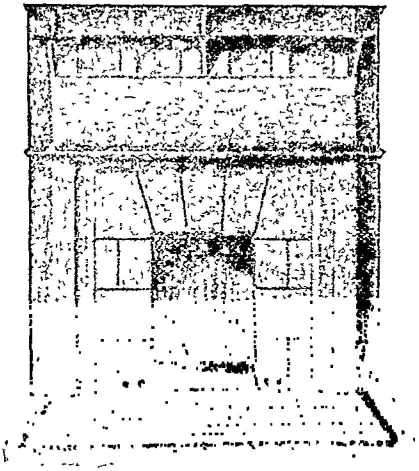
A jury was appointed by the society consisting of members of the council as well as of gentlemen possessed of technical knowledge but having no connexion whatever with the society. Rules were drawn up for the conduct of the tests. These rules were designed to secure that the tests should be exactly of the same nature for each competitor. A sitting-room on the ground floor of a building in Delahay street, Westminster, was placed at the disposal of the society by the courtesy of H.M. First Commissioner of Works and Public Buildings. The size of the room selected was 21 feet 6 inches by 14 feet 6 inches by 10 feet 6 inches, and in order to ascertain the comparative heating power of the grates it was arranged that each grate should be worked so as to maintain the temperature of the air in the room at 20° F. above that of the outside air. The two glass windows in the room were accordingly kept shut as was an ordinary door giving access to a small passage opening into the street. The street door also was, whenever possible, kept shut and as the chimney was 69 feet high an ample draught was obtainable.

FIG. 1.



Grate No. 1. The "Heaped" Fire. (Bratt, Colbran, and Co.)

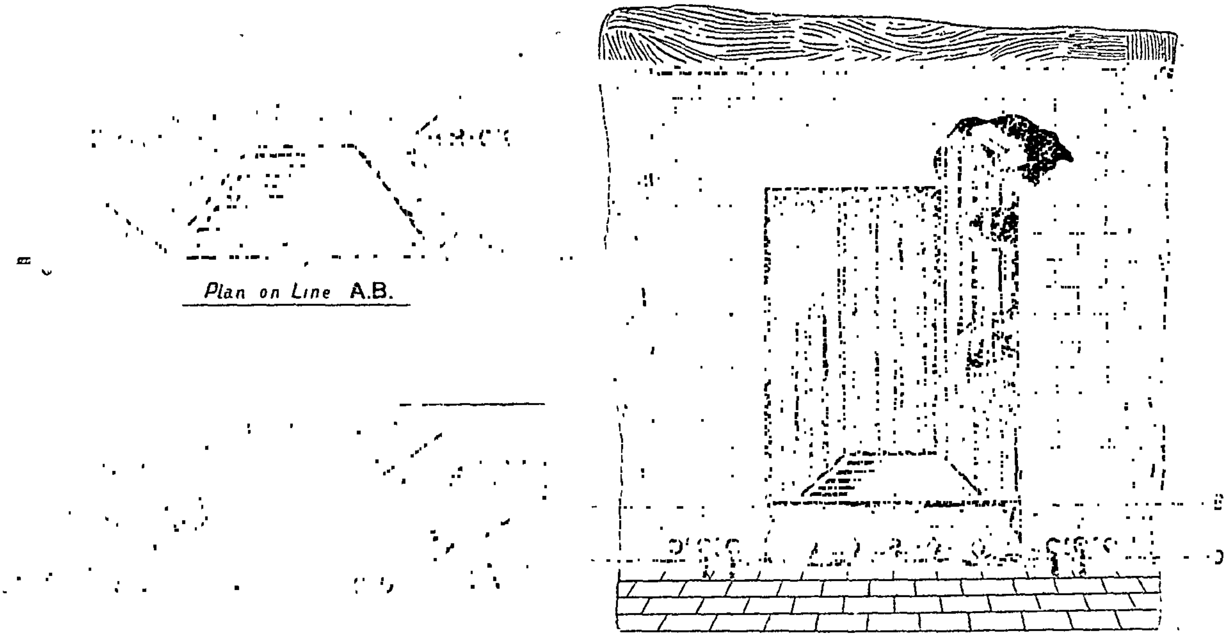
FIG. 2.



Grate No. 2. The "Tropican." (Chavasso and Kerr.)

The jury met at the Crystal Palace and selected certain stoves as appearing most likely to satisfy the conditions imposed and the grates so selected were fixed in position by the exhibitors who each gave written directions as to the manner in which the grates were to be treated but who, by arrangement, were not present during the trial. The tests of each grate were continued for a period of three days. The actual tests were carried out by an assistant acting under the direction of the jury. He was suppled with scales for weighing the coal used and thermometers for indicating the temperature of the air in the apartment and also of that in the hall outside. He was instructed to light the fires at 9 A.M. in accordance with the written directions of each competitor and to urge the fire until the thermometer, suspended in the middle of the room from the ceiling, showed a temperature of 20° F. above that of the air in the hall outside and so to regulate the fire as to keep the heat up to that point during the day. The coal and wood used were carefully weighed and the amount recorded and the time of each stoking noted. At 5 P.M. each day the fire was drawn and, when cold, the unburnt cinders were weighed and the amount deducted from that of the coal put during the day on the fire. Throughout each day another assistant in an upper room of a house on the opposite side of the street at an angle of about 30° from the top chimney and about 35 feet away, commanding a clear view of the chimney which carried the smoke of the stove under investigation, was directed to observe the intensity of the smoke. The amount of smoke emitted was carefully recorded on a chart every five minutes by means of the series of smoke tints designed by the late Mr. Bryan Donkin. There was no communication between the two assistants and members of the jury visited the respective

FIG. 3.

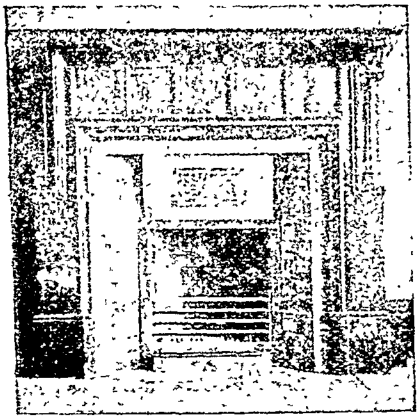


Grate No. 2. The "Tropican." (Chavasse and Kerr.)

rooms from time to time to satisfy themselves that the tests were being carefully carried on and the results correctly noted.

On the completion of the tests, which together occupied some weeks (one week being devoted to the setting, testing, and removal of each grate), the results of the observations were carefully tabulated and are now published as an appendix to this report. The amount of smoke emitted from the chimney was averaged. The amount of coal consumption in each case was also carefully averaged and the results arrived at are shown upon the plotted diagram. This diagram, therefore, shows at a glance the relative performance of each of the grates in respect of coal burnt, heat generated, and smoke consumed. Taking these three factors into account the jury had no difficulty in placing the competitive grates in the following order of merit :—

FIG. 4.

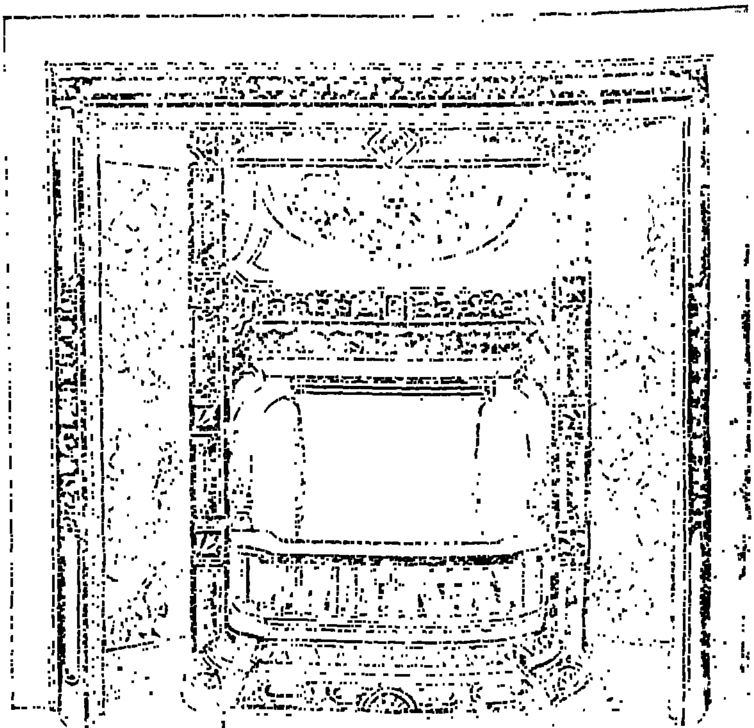


Grate No. 3. "Patent Grate." (Landers, Limited.)

1. The Tropican Grate—Messrs. Chavasse and Kerr.
2. Messrs. Landers' Grate.
3. The "Heaped" Fire—Messrs. Bratt, Colbran and Co.
4. The Francombe—Messrs. Clark, Hunt, and Co.

On the whole, it will be seen that the tests now concluded by the society show a distinct advance in the construction of grates calculated to diminish smoke. It is clear that if a market can be created for grates which will minimise the smoke nuisance such grates will be forthcoming. On the other hand, it is obvious that much of the smoke pollution caused by household fires is the result of careless or inefficient stoking. A fire is allowed to burn low and is then made up by a large amount of coal which cannot speedily ignite and which gives off quantities of smoke.

FIG. 5



Grate No. 4. Francombe's "Warm Air" Slow Combustion. (Clark, Hunt, and Co.)

A certificate was awarded by the Coal Smoke Abatement Society to the successful competitors indicated in the foregoing list of the *order of merit*. In this certificate the society certifies that on a series of tests conducted by the society and on a comparison between the grates entered for

competition being made it was found that the Tropican grate showed the best results in the diminution of smoke, the heating power of the grate, and the economy of fuel. This certificate is signed by W. B. Richmond, president; H. A Des Vœux, honorary treasurer; Owen B. Thomas, honorary secretary; and Lawrence W. Chubb, the secretary of the society.

In conclusion the Coal Smoke Abatement Society desires to record its indebtedness to the jurors who conducted the tests and to Mr. R. Bailey, controller of the stores at H M Office of Works and Public Buildings, whose services rendered the experiments possible, and to Sir Schomberg McDonnell, secretary to the Commissioners of H M Office of Works, for granting the society permission to conduct the tests in a building under the control of his department.

Grate No 1.[1]—The "Heaped" Fire (patent) This grate questions of Dr. Parsons and had received the reply that they could not be answered without the consent of the patient. He added, however, that Dr. Parsons, being called as a witness before the coroner at the inquest upon the body of a child, had given evidence bearing upon the subject in question. The solicitor in making his statement with regard to what had taken place appears to have laid special emphasis upon the fact that the infirmary was a rate-aided institution and the magistrate, Mr. Marsham, made reference to this in commenting upon the incident. Mr. Marsham, however, is a gentleman of considerable experience in the discharge of his duties and he carefully refrained from speaking in condemnation of one who was not before him to defend his conduct. He was content to say in general terms that in a public institution such as an infirmary he would have thought that a medical man would do his best to assist justice, and to add that, in circumstances such as the inquiry before him *indicated*, there was *something to be said* upon both sides. With his conclusion no one will disagree. The police have their duties to perform and they naturally look at them from their own point of view In cases of the class under consideration they can point to the sacrifice of infant life which members of the medical profession equally with the rest of the community deplore and desire to see abated, and they can reasonably argue that the detection and punishment of cases of concealment of birth have some influence in the prevention of similar offences and of the crimes often connected with them. This, however, does not affect the position of the medical man when information is sought from him by detectives as to the physical condition of a patient intrusted to his care, whether the patient be a rich man or woman attended in his or her private house or a poor one lying in the ward of a charitable institution. His duty is to respect the confidence of his patient and to guard the secret acquired in his professional capacity to the utmost in his power so long as to do so does not make him participator in a crime. Ethically he is under the same obligation with regard to the knowledge which he has acquired as the solicitor consulted by a client who has committed a wrongful act, or a clergyman to whom such an act has been confessed. In a court of law the solicitor has the advantage of the medical man and of the clergyman, for he cannot be compelled to state what he has learnt in the course of a consultation with his client. An attempt has been made on other occasions to trace cases of infanticide by means of the medical profession and the usefulness to the police of the informatian which might so be obtained is obvious. On the other hand, it is equally clear that if unfortunate women knew that their secret would at once be sought and obtained by the agents of the law from the medical man they would shun the infirmary and avoid the medical practitioner, however great their physical need and the danger to their lives. It would be a gross treachery for the medical practitioner to betray those who appealed to him for aid in the confident belief that their secrets were safe in his keeping and he would have no right to encourage such a belief or to permit it to exist unless it were well founded. A direct warning would, no doubt, prevent any charge of breach of faith being made, but if we imagine such a state of affairs in practice we have to picture to ourselves a notice in the entrance hall of a hospital or of a medical man's consulting room in a poor district couched in such terms as these: "All questions asked by the police with regard to patients will be promptly answered. Women recently delivered of children should note this warning" One effect of the intimation would be to destroy in the case of the hospital and of the medical practitioner that reputation of being the trusted friend of the sufferer without distinction of creed and without question as to moral conduct of which the medical profession and those responsible for the organisation of our hospitals are alike justly proud. Circumstances must govern the decision of the medical man in individual cases where he has good reason to believe that his patient has infringed the law, and the question that he must decide by the guidance of his conscience and of his sense of professional honour may be a very difficult one, but the police have no right to try to enrol him as a detective to aid in their preliminary inquiries into crime or to complain if he refuses to accede to their wishes. Still less are they justified in applying pressure upon him by holding him up to the magistrate as one who sympathises with breaches of the law. He may be said to have gained certain knowledge as a friend only, but few men of honour would betray a friend to the police unless the very strongest reasons of public duty were there to render the step necessary.

The Legal Test of Insanity.

At the Lancaster assizes recently in a murder case in which the defence of insanity had been suggested, Mr. Justice Jelf laid down with great emphasis the so called "legal test." He said: "To establish a defence on the ground of insanity it must be clearly proved that at the time of committing the act the party accused was labouring under such a defect of reason from disease of the mind as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know that he was doing wrong." The inadequacy of this definition has often been pointed out and many judges seem to have discarded it. Its chief weakness lies in the fact that it takes no note of that large class of cases which are grouped under the name "impulsive insanity." Mr. Justice Hawkins (now Lord Brampton), in the well-known case of the man Ware who killed a fellow patient in an asylum, said that the prisoner knew that he had killed a man because he said himself that he had, he also knew that it was wrong for he asked for a promise that he would not be punished if he gave up his weapon, yet his lordship continued: "No man in his senses would suppose that any jury would find Ware responsible for what he had done." Again, the late Mr. Justice Stephen held that the law allows that a man who by reason of mental disease is prevented from controlling his conduct is not responsible for what he does. The late Lord Chief Justice Cockburn dissented from this as an interpretation of the law as it stands but agreed that such an alteration was advisable as would cover these cases of inhibited control. It is gratifying to find so many eminent judges taking this enlightened view and it is to be hoped that before long the other occupants of the bench will see the matter from the same standpoint.

An Action for Negligence in the Application of the Roentgen Rays.

An account of an action for negligence recently tried at Dublin and arising out of injuries sustained by a child through the use of the Roentgen rays will be found in the letter of our Irish correspondents at p. 544. The defendants, it will be seen, were the president and professors of the Queen's College, Galway, a man named Haire employed in the College as mechanical assistant in the Natural Philosophy Department, and Dr. Nicholas W. Colahan, a medical man who desired to locate a needle supposed to have entered the knee of a child, his patient. The apparatus employed belonged to the College and was used as a rule for the instruction of students, but Mr. Haire was apparently permitted to make radiographs with it for the benefit of local medical men and had done so before in about 50 instances. Dr. Colahan was present when Mr. Haire used the apparatus upon the plaintiff and also on one occasion used it himself in Mr. Haire's absence. In these circumstances the first question with regard to the College authorities was whether they had undertaken any duty with regard to the plaintiff and it was abundantly clear that they had not. With regard to the two other defendants, the case against them depended upon the proof of their alleged negligence as shown by the condition of the child's leg and by the evidence of his mother and sister as to the manner in which the rays had been applied. This evidence was not only directly contradicted by two of the defendants but the account given was inconsistent with the radiographs produced before the jury, which could not have been made had the bulb been kept at the distance of two inches from the limb described by the little boy's relatives. A considerable body of expert evidence was also called and made it clear that no negligence had been proved against either Dr. Colahan or Mr. Haire. The action shows a certain lack of gratitude on the part of the parents of the child for the efforts made to assist them by all involved.

ASYLUM REPORTS.

Gartloch Asylum, Glasgow (Report for the year ending May 15th, 1903).—The average number of patients resident during the year was 613, comprising 312 males and 301 females. The admissions during the year amounted to 285—viz., 151 males and 134 females. Of these 197 were first admissions. Dr. W. A. Parker, the medical superintendent, states in his report that alcohol stands pre-eminent as the chief cause of insanity in the cases admitted. Next in importance was senile decay as a cause of insanity. A strong hereditary predisposition to insanity or nervous disease was ascertainable in one-fourth of the cases in which a family history could be obtained. The number of patients discharged as recovered during the year amounted to 114—viz., 59 males and 55 females, or 18·6 per cent. of the average number resident. The deaths during the year amounted to 70, or 11·4 per cent. as calculated on the same basis. Of the deaths four each were due to senile decay and cerebral syphilis, five to cardiac disease, six to bronchitis and broncho-pneumonia, six to pulmonary and other forms of tuberculosis, 17 to general paralysis of the insane, and the rest to other causes. A sanatorium for the treatment of tuberculous patients was opened in December, 1902, and although it is too soon, adds Dr. Parker, to attribute the low death-rate from tuberculosis during the year to the sanatorium its use must be regarded as having helped to lessen the death-rate. This building is one storey high and is situated on rising ground to the north-west of the asylum buildings. It faces due south and has been planned [illegible] There is one large [illegible]'s, with four attached [illegible]nodation of 60 beds. [illegible]t broad and gives an [illegible]ead. The wards and rooms are lighted by electricity and heated throughout by a system of hot water pipes. The sanatorium is supplied with a septic tank installation for treating its sewage, while a steam disinfector has been erected to deal with all clothes before going into the common laundry. The Commissioners in Lunacy state in their report that the condition of the patients as regards clothing and personal appearance indicated due and proper attention on the part of those in charge of them, that the old and feeble bore evidence of being kindly cared for, that the wards were bright and comfortable, that the bedding was in excellent condition, and that the medical case books were well and carefully kept. The committee of management states in its report that the 60 beds of the sanatorium are fully occupied and "have proved a great boon by removing many infectious and objectionable inmates from among the others." Additional farm land to the extent of 93 acres has been purchased to increase the supply of farm-grown meat and vegetables.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8684 births and 5396 deaths were registered during the week ending Feb. 13th. The annual rate of mortality in these towns, which had been 18·1, 19 4, and 17·2 per 1000 in the three preceding weeks, rose again last week to 18·4 per 1000. In London the death-rate was 17·7 per 1000, while it averaged 18·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·0 in Smethwick, 6·3 in Northampton, 8·4 in Aston Manor, 9 0 in Hornsey, 10·7 in East Ham, 10 9 in York, 11·0 in Hastings, and 11 2 in Walthamstow and in Wallasey; the highest rates were 23·6 in Birkenhead, 26·2 in Bootle, 26·5 in Gateshead, 27·7 in Rhondda, 27 9 in Warrington, 28·5 in Bury, 28·8 in Swansea, and 29·2 in Newport (Mon.). The 5396 deaths in these towns last week included 449 which were referred to the principal infectious diseases, against 427, 497, and 412, in the three preceding weeks; of these 449 deaths 182 resulted from whooping-cough, 93 from measles, 61 from diphtheria, 43 from diarrhœa, 32 from "fever" (principally enteric), 31 from scarlet fever, and seven from small-pox. No death from any of these diseases was registered last week in Hornsey, Tottenham, Walthamstow, Hastings, Northampton, Burton-on-Trent, King's Norton, Aston Manor, Derby, Wigan, or Barrow-in-Furness; while they c[illegible] Great Yarn[illegible] Gateshead. [illegible] measles oc[illegible] and Sunder[illegible] diphtheria in Great Yarmouth and in Bury; from whooping-cough in Leyton, Wallasey, Liverpool, Bootle, Bury, Stockton-on-Tees, West Hartlepool, Gateshead, Newport (Mon.), and Swansea; and from "fever" in Preston. Of the seven fatal cases of small-pox registered in these towns last week, four belonged to Gateshead and one each to Nottingham, Hull, and South Shields. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 24, 21, and 25 at the end of the three preceding weeks, had declined again to 24 at the end of last week; three new cases were admitted during the week, against three, four, and eight in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, Feb. 13th, was 1644, against 1679, 1651, and 1657 on the three preceding Saturdays; 162 new cases were admitted during the week, against 180, 168, and 169 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 353, 429, and 347 in the three preceding weeks, further declined last week to 324, but were 57 above the number in the corresponding period of last year. The causes of 55, or 1 0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Bradford, Leeds, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Leyton, Liverpool, St. Helens, Warrington, Sunderland, South Shields, and Rhondda.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·8, 18·4, and 18·5 per 1000 in the three preceding weeks, further increased to 19·2 per 1000 during the week ending Feb. 13th, and was 0·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 6·2 in Perth and 14·3 in Leith, to 23·0 in Paisley and 24·6 in Dundee. The 636 deaths in these towns included 24 which were referred to whooping-cough, 21 to measles, 20 to diarrhœa, three to diphtheria, two to scarlet fever, one to small-pox, and one to "fever." In all 72 deaths resulted from these principal infectious diseases last week, against 54, 62, and 44 in the three preceding weeks. These 72 deaths were equal to an annual rate of 2·2 per 1000, which was 0·7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 11, 16, and 15 in the three preceding weeks, increased again last week to 24, of which nine were registered in Aberdeen, six in Glasgow, three in Paisley, two in Dundee, and two in Leith. The deaths from measles, which had been 19, 12, and seven in the three preceding weeks, rose again to 21 last week, and included 11 in Glasgow, five in Dundee, and four in Paisley. The fatal cases of diarrhœa, which had been 14, 17, and 11 in the three preceding weeks, rose again last week to 20, of which nine occurred in Glasgow, four in Aberdeen, two in Edinburgh, two in Dundee, and two in Greenock. The deaths from scarlet fever, which had been six and three in the two preceding weeks, further declined last week to two, both of which were recorded in Glasgow, where the fatal case of small-pox also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 167, 128, and 129 in the three preceding weeks, declined again last week to 126, but were 14 in excess of the number in the corresponding period of last year. The causes of 21, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26 0, 25 6, and 30·5 per 1000 in the three preceding weeks, declined again to 27 2 per 1000 during the week ending Feb. 13th. During the past four weeks the death-rate has averaged 27 3 per 1000, the rates during the same period being 18 0 in London and 16 5 in Edinburgh. The 198 deaths of persons belonging to Dublin registered during the week under notice were 24 below the number in the corresponding period of last year and included ten which were referred to the principal infectious diseases, against eight, 14, and 12 in the three preceding weeks; of these, six resulted from whooping-cough, two from diarrhœa, one from diphtheria, and one from "fever," but not any from small-pox, measles, or scarlet fever. These ten deaths were equal to an annual rate of 1·4 per 1000, the death-rates last week from the principal infectious diseases being 1·4 in London and 0 5 in Edinburgh. The fatal cases of whooping-cough, which had been five, 11, and nine in the three preceding weeks, further declined last week to six. The 198 deaths in Dublin last week included 36 of children under one year of age and 59 of persons aged 60 years and upwards; the deaths both among infants and among elderly persons showed a marked decline from the number in the preceding week. Three inquest cases and five deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions. The causes of five, or nearly 3 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon J. Bradley to the *Essex*. Staff Surgeons: E. Cooper to the *Astræa* and P. H. M. Star to the *Fire Queen* for the *Nelson*. Surgeons: E. S. Wilkinson to the *Astræa* and C. A. G. Phipps to the *Essex*.

ROYAL ARMY MEDICAL CORPS.

Major S. Macdonald proceeds to Woolwich for duty. Major R. Caldwell has left Aldershot for India. Captain E. S. Clark joins the Home District for duty from the Royal Army Medical College. Lieutenant W. F. Tyndale, C.M.G., and Major A. P. Blenkinsop have embarked for India.

Captain P. S. Lelean, from the Seconded List, to be Captain (dated Dec. 14th, 1903).

VOLUNTEER CORPS.

Rifle: 8th (Scottish) Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Captain J. C. Macalister to be Surgeon Major (dated Feb. 13th, 1904). The undermentioned Surgeon-Lieutenants to be Surgeon-Captains:—A. G. Gullan (dated Feb. 13th, 1904) and W. S. Henderson (dated Feb. 13th, 1904). 19th Middlesex (Bloomsbury): The transfer of Surgeon-Captain W. N. Evans, from 1st Volunteer Battalion the Middlesex Regiment, bears date Sept. 12th, 1903.

NATIONAL PHYSIQUE AND AN IDEAL ARMY.

We have been favoured with the reprint of an article on this subject which appeared in the *Army and Navy Gazette* of Feb. 13th. It is the purpose of Dr. Arthur H. Rideal, the author of the article in question, to set forth a scheme which he tells us he has been studying for some time and has had numerous opportunities of discussing with army men, volunteers, and civilians. So far as concerns the improvement of the physical culture, drill, and training of the youth of this country the subject is rightly regarded as one of great national importance and we concur in thinking that something on the lines of Dr. Rideal's proposals will sooner or later have to be adopted if we are to avoid the Continental system of conscription. We all know how the average schoolboy loves "to play at soldiers" and we have only to encourage and to develop this natural instinct in order to improve youths in physique and to imbue them at the same time with some idea of the importance of their duties in the future as citizens and soldiers and defenders of the empire. The work, it is contended, only requires to be undertaken and systematically carried out with the aid of properly qualified instructors belonging to the regular service and appointed for the purpose to prove successful. It is suggested that every boy who has attained the age of 12 (or 13) years—unless physically unfit or destined for the navy—should be compelled to commence a five years' course of drill and instruction calculated to fit him for a place in the ranks of the army, and the necessary organisation and way in which this might be done are set forth in the article under notice. There should be no lack of material, for "at the last census there were in the United Kingdom no less than 425 000 boys between the ages of 12 and 13. If we deduct the very high proportion of 40 per cent. as being physically unfit there still remain more than 250,000 boys each year to deal with and in eight years from the initiation of the scheme we should have over a million well-trained young men at our service in case of need, and in the course of time every able-bodied man in the kingdom would be sufficiently trained to at once take up arms in defence of the empire." With regard to those portions of Dr. Rideal's article referring to a standing army, the short-service system, the militia, and as to what would be the financial effect of his scheme we can express no opinion. We must leave these to the consideration of experts and military authorities. But as to the advantage of his scheme for the training of youth in a physical sense and as a national basis for recruiting the army we entertain little or no doubt.

WAR OFFICE CHANGES: DOING AND UNDOING.

A number of most important and radical reforms have already taken place in connexion with the recommendations of the War Office Reconstruction Committee. The Committee of Imperial Defence, under the presidency of the Prime Minister, has been reconstituted; an Army Council has been established under the Secretary of State for War and the appointments thereto have received the approval of the King and have been published in a special edition of the *London Gazette;* Earl Roberts, in consequence of the abolition of the office of Commander-in-Chief, has retired from the War Office but retains his seat on the Committee of Imperial Defence; and, last of all, the Duke of Connaught has, it is alleged, been selected by the Army Council to fill the newly created post of Inspector General of the Forces. But amid these sundry and manifold changes in the War Office world there is one thing conspicuous by its absence. All that was done after very full and deliberate consideration by the late Secretary of State for War for the direct representation of the medical service has apparently been ignored and left undone by his successor in that office. We briefly alluded to this omission last week as a matter of surprise to us but supposed that it was nevertheless intended that provision must and would be subsequently made somehow for a matter of such vital importance to the nation and the efficiency of the army. After all that has taken place and with the facts connected with the late war in South Africa still fresh in the public mind it is impossible to believe that we are to revert to the old state of things and that the medical service is not to be represented adequately and prominently in the councils of the War Office. It is a point on which we have dwelt again and again in the past and we had congratulated our readers on the fact that owing to changes introduced in Mr. Brodrick's time the head of the Army Medical Service had at last been put in a proper official position where his representations and influence would really be of use. Mr. Arnold Foster will assuredly have to see to this matter and we are glad to notice that it has not escaped the attention of the British Medical Association.

Correspondence.

"Audi alteram partem."

THE VALUE OF COD-LIVER OIL.

To the Editors of THE LANCET.

SIRS,—In the annotation on the adulteration of cod-liver oil in THE LANCET of Feb. 6th, p. 378, mention is made of a communication by my brother, Mr. E. J. Parry, calling attention to the large amount of substitution of other oils taking place during the present scarcity. Of this I have nothing to say beyond the fact that it behoves all medical men to make a point of seeing that their patients procure their oil from a trustworthy source. The point in the article to which I wish to refer is his suggestion that the value of cod-liver oil is largely traditional. With this I must, on the whole, agree. The value of cod-liver oil depends more on the ease with which it is absorbed and assimilated than on any specific virtues which it possesses. Any other fat which is equally readily absorbed and assimilated would be just as good. But I think that the fact that the accumulated experience of many generations that cod-liver oil is the best medicine for the various wasting diseases tends to show that, so far, no other fat has been discovered which is so readily absorbed by the human intestine. There are many other fats which are of great value (I am, for instance, in the habit of ordering a few teaspoonfuls of liquid bacon fat at breakfast to children who are unable to take cod-liver oil), but I believe, on the whole, that there is nothing quite equal to cod-liver oil, no fat which is so well assimilated by children, and therefore that, while undoubtedly tradition plays some part in the value attaching to this substance, so far we have no substitute of quite equal value.

I am, Sirs, yours faithfully,
L. A. PARRY, M.D. Lond., F.R.C.S. Eng.,
Hon. Assistant Surgeon, Royal Alexandra Hospital for Sick Children, Brighton.
Hove, Sussex, Feb. 12th, 1904.

CHLORETONE IN SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—Mr. L. E. Ellis will find, I think, that chloretone is far more successful with women than with men. I have just had a letter from a lady from Marseilles: "Thank you a thousand times for the 'cure' It is a grand success. As you know, I am not a good sailor, but I have not been sick at all and we really had a pretty bad time. Out of 43 ladies only one besides myself put in an appearance at breakfast About an hour after we left Plymouth I felt queer and took one capsule and after that one night and morning." On the other hand, I have heard of its failure with men. I believe that it is efficacious only in sea sickness of nervous origin, with cold extremities, giddiness, and horrible depression. It seems to be useless in stomach sea-sickness where the chief symptom is the vomiting of frothy mucus and where the nervous symptoms seem to be only secondary to the sickness. Men suffer much more from the latter than the former kind.

I am, Sirs, yours faithfully,
Silverton, Feb. 15th, 1904. O. CLAYTON JONES, M.B. Oxon.

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of THE LANCET.

SIRS,—One of the objections to writing prescriptions as opposed to giving medicines is that patients sometimes hand them over to friends of theirs who are supposed to be suffering from the same disease, which may be, however, an entirely different one. Even if the malady really be known to be the same, two people would probably receive from a physician at any rate not exactly the same treatment. A great many people, however, are not aware that subtle distinctions have to be made, and hence much mischief may, even with the best intentions, be produced. Sometimes, too, people who assume some of the duties of a medical man may from prescriptions gain a confidence which, though really misplaced, may yet lead them to act to the disadvantage of both the public and the medical profession in other ways. I am, Sirs, yours faithfully,
Grimsby, Feb. 10th, 1904. GEORGE GRESSWELL.

To the Editors of THE LANCET.

SIRS,—May I say in reference to the letter by "A Chemist and *Druggist*" in THE LANCET of Feb. 13th, p. 464, that, although what he says as to quack medicines is true and wise, he is altogether mistaken in supposing that "the prescribing chemist, speaking broadly, is non-existent." Let him try the experiment next time he takes a holiday of going into the nearest druggist's shop and asking for a bottle of medicine to relieve some simple symptoms. Scores of my friends have told me that they often get medicine in that way when from home, for it is cheaper and more convenient than going to a medical man, and that on no occasion have they ever been refused. I used to practise in a town of 10,000 inhabitants and there the commonest introduction to a statement of symptoms was: "I went to the chemist, but the medicine he gave me has not done much good, and I thought it better not to let it go on any longer so I have come to you." The public would be most indignant if any attempt was made to prohibit druggists from prescribing for simple ailments. A man with an attack of diarrhœa will not go to a medical man, as a rule, if he knows that from there he will have to go on to the druggist He will go to the druggist first and, if not cured, will then go to the medical man. I believe this is the rule all the country over and I am sure that it is useless to alter it by Act of Parliament It is no use legislating for an ideal social state. Human nature must be taken as it is.

I am very glad to hear from Mr. J Smith Whitaker that this dispensing clause is not the handiwork of the medico-political committee of the British Medical Association One can understand an individual member practising in the Central London division showing such a complete ignorance of the conditions of country practice. I think he would show more wisdom if he altered his suggested clause so as to make it apply only to the kind of practice he is conversant with. As it stands it would deprive thousands of hard-working medical practitioners of their means of livelihood, for it would reduce their incomes below a living wage. I hope the Central London division will understand this and at once reject the suggested clause and so set at rest the minds of so many of their anxious brethren. My experience is that the medical profession takes a higher social position in the country than it does in the town and that therefore country practitioners can be safely trusted, without compulsion, to avoid what is derogatory, wanting in tone, or even vulgar.

I am, Sirs, yours faithfully,
Feb. 15th, 1904. PAGANUS.

To the Editors of THE LANCET.

SIRS,—The thorny question of dispensing by medical men in general practice cannot, it is evident, be settled on similar lines for those in town and country and for those who do and those who do not employ an assistant. Nor can it be dealt with apart from the regulation of prescribing by druggists on stricter lines than at present. To most practitioners dispensing is not so much *infra dig.* as simply an unpleasant and time absorbing nuisance. To the younger men it is often their one way of learning to prescribe. In very many cases the patients regard the fee as paid not so much for the advice as for the physic, and therefore many medical men are compelled against their better will to give medicine when it is not strictly necessary, and yet—undignified as such procedure is—how many of those who complain that their vested interests would be endangered by the restriction of dispensing will have the courage to demand payment for skill and knowledge rather than for mere physic? It must surely have often occurred to the conscientious general practitioner that reform on concerted lines was required and that if not [illegible] nsing [illegible] In a- [illegible] It has [illegible] We are obliged in self defence or self-regard to "pile on physic" *per fas atque per nefas.*

I am, Sirs, yours faithfully,
Feb. 8th, 1904. VERITAS.

To the Editors of THE LANCET.

SIRS,—With reference to the proposed additional clause to the Medical Acts Amendment Bill to prevent medical men from dispensing their own medicines except in special circumstances, I beg to offer my views on the matter. I may say that I am a country practitioner with clubs and I dispense my own medicines. I do not think any of your correspondents have tried to get to the root of the matter and to ask themselves what there is in the present system of dispensing our own medicines which is so wrong as to make some of us consider that the only remedy is to stop the medical profession from dispensing as far as it is possible to do so. What, then, is the object of the proposal? and out of this necessarily arises a second question—What alternative system is to be proposed? The first question may be answered to the point as follows: To prevent unscrupulous men from treating their patients simply by giving a bottle of medicine without having made any attempt to form an accurate diagnosis and, moreover, charging exorbitantly for services rendered thereby. That is the evil that unquestionably exists and equally unquestionably we should attempt to drive it out of our honourable profession. The result is injurious to the public and to the profession. Who amongst us has not seen a case admitted to any of the large hospitals in a condition aggravated by the neglect of the medical attendant? And who amongst us does not see the harm that is daily being done to our profession by practitioners running cheap dispensaries which only pay by the number of bottles of medicine that are dispensed, and by the unprofessional attitude of men in the matter of clubs, which is well illustrated in your article in THE LANCET of Feb. 13th on the Battle of the Clubs at Southampton? But, it will be asked, how are you going to stop this evil, by preventing medical men from dispensing their own medicines? The probability is that you will create a worse evil by driving the patient, who at present consults you and who can only afford a small fee, to consult the druggist who has no business to try to make a diagnosis. The answer to this question is, of course, the answer to my second question as to what alternative to the present system is proposed and I am not so foolish as to think that I have got a cut-and-dried remedy. We must have the views of men conversant with the matter, as to the conditions existing in countries where medical men do not dispense, and in this respect I consider Dr. D. W Samways's communication the most valuable one THE LANCET has yet received. If this proposal, which is to raise the standard of the profession and to protect the public, is to have its effect there must be a simultaneous proposal to prevent druggists from supplying medicines without a prescription and some system of endorsement by a medical practitioner of a prescription which has been already dispensed a given number of times. The present uncontrolled sale of patent and proprietary medicines must also be stopped. The difficulties of such a system are, of course, only too obvious and the only alternative seems to be to fight with the weapons which are being used against us and to establish a trade union, or else to leave matters as they are and to trust to the moral education of the practitioner to bring about a remedy. This latter alternative, I think, is the only feasible one, and I may add with reference thereto that I consider the present tendency to minimise the value of a good general education to a medical man, as may be exemplified by the professional privileges allowed at the universities, is the root of the evil.

I am, Sirs, yours faithfully,

Feb. 13th, 1904. ARZT.

To the Editors of THE LANCET.

SIRS,—A great deal has been written and will probably be written on this most momentous question of dispensing. But so far surely all your correspondents have lost sight of a very important matter, not so much the advantages or disadvantages of dispensing as the advantages that are given to the prescribing druggist and quack. Until these two are put down, and only then, will, I think, it be possible—or shall I say fair—to stop medical men from dispensing. If dispensing practitioners are stopped now thousands of pounds will go into the pockets of these illegitimate trades and the legitimate one will perforce go to the wall, forsooth because a certain body of men think they will raise the status of the profession. Surely it is the man who makes his position; you cannot make a silk purse out of a sow's ear. Why, I ask, is it more *infra dig.* to dispense one's own medicines than for a clergyman to write his own sermons or a lawyer to write briefs for his counsel? It is part of their livelihood, so anything appertaining to medicine is part of ours. Some of your correspondents' ideas are wide of the issue, and one in particular shows a want of knowledge when he suggests that no medical man should be allowed to attend a friendly society under 5*s.* per member per annum and the society to find everything else. I believe most friendly societies pay 4*s* per member per annum, everything included. I am afraid he is wofully ignorant of the working man if he thinks he will get him to pay more and receive less than he now does. I dispense my own medicines, as do my other brother practitioners in this town, and yet every market day we are exposed to the insults of a quack who has a stand in the market and dispenses medicines without let or hindrance. Where is this noble body of men who allow this to continue openly? Their one object seems to be to enrich this class and to starve out many who have spent both time and money on their education.

I am, Sirs, yours faithfully,

Feb. 7th, 1904. IN RECTO FIDES.

LEPROSY.

To the Editors of THE LANCET.

SIRS,—I have been asked to prepare a paper for the Dermatological Congress which takes place at Berlin next September, the subject given to me being British India—the Condition of the Spread of, and Fight against, Leprosy since the First International Conference in 1897, the heads under which I am to write being the following:—

1. *Statistics*—(*a*) According to official reports (Government); and (*b*) asylums, colonies (mission). What kind of asylums—sex and age of inmates.

2 *Methods employed to fight leprosy between 1897 and 1903 (inclusive)*.—(*a*) Laws of Government; and (*b*) activity of Government or of private societies for the suppression of leprosy, municipalities or parishes, &c. (1) Number of asylums or colonies; (2) number of places; (3) how the patients get about; (4) occupation of lepers in asylums; and (5) conveying of lepers by train, steamer, &c.

3. *The condition of lepers in infirmaries and surgery wards.*

As I am anxious to have the paper as accurate as possible it will be a great favour if any of your readers who have information on the above points and for the period indicated will kindly communicate with me.

I am, Sirs, yours faithfully,

WELLESLEY C. BAILEY,
Secretary and Superintendent,
Mission to Lepers in India and the East.

17, Greenhill-place, Edinburgh, Feb. 11th, 1904.

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Permit me to express my approval of the strictures you have recently passed upon the treatment which certain of the assistant medical officers of the Metropolitan Asylums Board have received. I myself have an unpleasant recollection of the cavalier methods of the Board. At a time when they (wrongly) anticipated an increase in infectious diseases I was appointed one of four assistant medical officers out of 11 selected candidates but was kept waiting six weeks before allocation to a fever hospital and then only after initiating a lengthy correspondence with the Board. I was accommodated with a box-room for a bedroom, devoid of fireplace, unhygienic, and eminently uncomfortable. A few weeks afterwards I was requested, through the medical superintendent, to take up lunacy work in one of the asylums of the Board, his inducement being "that if I considered the Board the Board would consider me." I consented to do so temporarily but heard nothing further, not even as to whether the Board approved of my decision or not.

Shortly afterwards, during the renovation of the official block, I was asked, along with other assistant medical officers, to sleep in a ward which a few weeks before had been used for the accommodation of enteric fever patients. I declined, as I much objected to sleep in any such ward whatever the method of disinfection, but was quite willing to put up with *the most primitive accommodation* anywhere in the official block. This was most ungraciously assented to and only on condition that I rose every morning at 6 30 to admit workmen to my room, but no workmen, until fully ten days had elapsed, availed themselves of the extra hours. The light in my room was cut off and no substitute was furnished. A few days later the subcommittee intimated to me that it did not find itself in the position of recommending the hospitals committee to confirm me in my appointment and the committee would be asked to terminate it *nine days after the receipt of its letter.* I, however, insisted upon giving a month's notice. The action of the Board very seriously modified my plans for the future and necessitated a most serious curtailment of research work I was engaged in during my leisure.

This bare statement of facts indicates what the Board is capable of doing in the way of considering an assistant medical officer who was ready and willing to consider the Board.

I am, Sirs, yours faithfully,

EX-A.M.O.

Feb. 15th, 1904.

THE INQUEST ON WHITAKER WRIGHT.

To the Editors of THE LANCET.

SIRS,—I observe that there is still a dropping fire of remarks on the trial of the late Whitaker Wright and on the subsequent coroner's inquest, and yet what seems to me by far the most important oversight in the latter has apparently passed without any commentary either in THE LANCET or elsewhere. Was it not a matter of clear duty in conducting this inquest to inquire minutely and even suspiciously as to how the suicide became possessed of the poison by which he made away with himself? Admitting, as was suggested by the coroner to a witness, that Whitaker Wright was familiar with cyanide of potassium as employed in the arts and that he may have had unusual opportunities thereby for the possession of it, is it not the case that under a very strict law the sale of cyanide of potassium or of any similar poison has to be registered carefully by the seller as well as the purpose to which it is to be applied. How was it that no directions proceeded from the coroner to investigate carefully this point and without loss of time? What dealer had so completely set aside the letter and the spirit of the "Poisons Act" and how comes it that the whole press of the country (so far as I have remarked) has passed over this subject without criticism. No doubt it was easier for a man familiar with the use of the cyanides, even when he himself was watched and suspected, to obtain them than it would be for others, but still he must have employed an agent, and as we are informed that he got the poison in the form of capsules it stands to reason, one would think, that the delivery of those capsules ought to have been diligently sought out and the question raised and decided at the inquest whether there was a violation, and a criminal violation, of the "Poisons Act," yet no trace of such inquiry remains except in the fact that the coroner, as if anxious to help a witness over a difficulty, suggested that Whitaker Wright's familiarity with the cyanides made it, as it were, quite easy for him to have them in his possession in that particular form. As a Scotsman I am not familiar with coroner's inquests or the proceedings that may be ordered under them, but I cannot help thinking that here is a case of negligence which should have been avoided in the public interest. I am, Sirs, yours faithfully,

Feb. 13th, 1904. MIDLOTHIAN.

SMALL-POX IN THE LEVANT.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

THE spread of cholera in Syria and Mesopotamia and the occurrence of occasional cases of plague in Egypt and elsewhere have attracted more attention than the prevalence of small-pox in the Near East, although the latter has probably caused a far higher mortality than the other two diseases put together.

In Constantinople small-pox has been mildly epidemic during the past two months. It is probably rarely absent altogether from this city, although it usually causes but a [illegible] e weekly mortality bulletins. The [illegible] small-pox deaths week by week [illegible] beginning with the week ending Oct. 18th, 1903: 1, 3, 2, 0, 1, 6, 7, 7, 4, 6, 6, 6, 7, 8, 3 6, and 14. The last and largest figure is for the week ending Feb. 7th. The cases have been scattered more or less all over the city, but the quarters most affected have been those of Kuskunjuk on the Asiatic side of the Bosphorus, Hasskeui and Sultan Ahmed on the two sides of the Golden Horn, and Pera.

Smyrna has been the scene of a severe epidemic of the disease since the middle of last year. A single death from it occurred in each of the first four months of the year. Then in May there were three deaths, in June eight, in July 81, in August 199, in September 268, in October 134, in November 37, and in December 10. Occasional cases are still reported as occurring in Smyrna.

In Aleppo small-pox was epidemic throughout the last three months of the year, particularly in the Macharka quarter of the town. At one time as many as five deaths a day from the disease were reported as occurring. Damascus has also been visited by an epidemic of the disease, but the figures have not yet been reported. Outbreaks of greater or less severity have also been observed in the islands of Chios and Mitylene In the former it was imported from Smyrna in the month of September, and though a large number of cases were seen there were only two deaths from the disease. In the latter small pox appeared towards the end of the year and invaded many villages in different parts of the island. The disease was reported from Prevesa, on the coast of Epirus, in December; while at Kavala, on the Ægean coast, it was seriously epidemic through the greater part of last year. From Kavala it spread to Pravista and many villages in the neighbourhood. At Samsoun, on the Black Sea, small-pox was prevalent to a serious extent in the earlier part of the year. In the first three months of the year the cases reported numbered 165 and the deaths 45. It has not been mentioned in recent reports from there, but in the near neighbourhood of Trebizond, on the same coast, a malignant outbreak occurred last month, causing as many as 20 deaths out of only 29 cases.

Other places in the Turkish Empire from which the presence of small-pox has been reported in the last few months have been Valona on the Albanian coast, Latakia and Tripoli on the Syrian coast, Van in Armenia, and the island of Samos. The intensity of the disease in these different places has varied considerably. In Constantinople it has been mild in character. In Smyrna, on the other hand, it has been malignant, the cases being mostly confluent and not infrequently hæmorrhagic. The outbreak near Trebizond must also have been of a peculiarly malignant character to judge from the proportion of deaths to cases.

The law relating to vaccination in Turkey is contained in the "Règlement sur la Vaccination" of the year 1895. Article 1 of this Règlement requires that every boy or girl attending a public or private school must be vaccinated unless they show evident traces of having had small-pox. Article 3 makes vaccination compulsory for all persons entering a Government office, a college, the army, or the police. Article 11 states that parents should have their children vaccinated during the first six months of life and Article 19 advises revaccination every five years. Free vaccination is ordered to be provided by the municipal or other Government authorities and other articles lay down in detail the method of performing the operation and recording the results. The Règlement is an excellent one if it were strictly applied. An Imperial Iradé was recently issued ordering its immediate and strict application. There can be no doubt that it had been much neglected recently both in the capital and other parts of the empire. The frequency of small-pox and the rarity or inefficient performance of vaccination in this country are shown by the large number of persons met with who have at some time or other had small-pox. Out of 17 persons forming the subordinate (native) staff of a certain establishment here I ascertained by a recent inquiry that as many as nine had had the disease.

Constantinople, Feb. 11th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Poisons Bill for India.—Increase of the Plague Epidemic.—Useless Inspections.

THE Poisons Bill for India has been passed but it remains for the local governments to carry it out. There will be no stereotyped lists of poisons, even for mercantile chemical manufactures, but the local governments will have wide powers to exempt at discretion both the persons engaged in the manufacture of such substances and the substances which they manufacture. In rural districts the sale of poisons will not be neglected, as in the case of the two principal ones, white arsenic and opium, control will be exercised either at the port of entry or under the Excise Act. The amount of poisoning by white arsenic, both of human beings and of animals, in India is probably very considerable—certainly much more than ever comes to light. Perhaps the most curious part of the new Bill refers to medical practitioners. There being no registration—not even any qualification—required for practice it was impossible to define what constituted a medical practitioner, so it is left to the courts to decide each case on its merits. Any other course would have necessitated what would amount to registration of practitioners.

The plague mortality throughout India, after remaining nearly stationary for several weeks, has again made a further advance. The number of deaths last reported was 21,302, an increase of about 4000 on the total of the preceeding seven days. The chief development is in Bengal, especially in the districts of Gaya and Patna, and in the Punjab. Plague has increased markedly also in the Central Provinces In Bombay city a further recrudescence is evident but in Calcutta the disease is apparently still dormant.

Medical inspection at the railway stations and at the bunders is still kept up in the Bombay Presidency which is as futile as it is oppressive. The Plague Commission reported against it and the absurdity of maintaining it is shown in the fact that plague has been prevalent in every district of the presidency. A petition signed by 4000 persons has at last been presented to Government and the grievance has also been brought repeatedly before the Government. Bengal and the Punjab have no restriction on travel and there are now no grounds for maintaining the system.

Jan. 29th.

THE PROPOSED LEGAL SHORTENING OF SHOP HOURS.

(FROM A CORRESPONDENT.)

THE passage in the King's Speech announcing that proposals for dealing with the hours of employment in shops will be submitted to Parliament this session is most welcome. It has always seemed an anachronism that whereas in most of the skilled trades strong adult artisans rarely work more than nine hours and sometimes only eight hours a day, young women are made to toil as shop assistants 12, and at times even 14, hours daily. Though the work may be defined as light work it is no light matter to have to remain standing all that time. Over and over again statistics, reports, and testimony have been published proving the excessive prevalence of varicose veins, displacements of the womb, and other evil consequences resulting from standing so long.

The Birmingham and District Early Closing Association has issued a handbill appealing to the public to take the matter in their own hands and to compel the shops to close early by refusing to shop late. But for one person animated with sufficient altruism to act up to this very reasonable suggestion there are scores who are ignorant and indifferent. Yet the movement is well supported. Favourable articles from the six leading Birmingham papers are quoted, as also the opinions of five well known practitioners of that town. Among these the late Mr. R. Lawson Tait said: "I have been horrified at the physical torture imposed by long shop hours. I have seen many a young woman whose epitaph ought to have been—Died from daily torture: 8 A.M. to 10 P.M." Mr. Jordan Lloyd says: "Weakened bodies and enfeebled minds are necessary consequences of prolonged confinement and monotonous occupation, whether behind the counter of a modern emporium or in the cell of an Eastern prison-house."

All this is sufficiently emphatic and what has been done in Birmingham to awaken the public conscience on the question has also been attempted in London and most of the large centres in this and many other countries. The principal result of an agitation which has now lasted for many years has been the securing in most towns of a weekly half-holiday for shop assistants and the passing of an Act compelling shopkeepers to provide seats. On inquiry, however, it would seem that the latter measure has been of little or no use. There are no statistics available, nor is it possible to speak in a very emphatic manner on this subject. Still, on questioning persons in the retail trade and secretaries of societies brought in contact with many shop assistants, I found that there is no enthusiasm manifested. Briefly put, the impression is that the legal imposition of seats has only done good as a means of propaganda. It has made people think about the matter and those employers who are animated by a kindly and humanitarian concern for their assistants have encouraged them to sit down when they could do so without neglecting their business. But this was done before the passing of the Act and these good, kindly employers are, it is painful to state, but a very small minority. Now the law has stepped in and says that seats must be provided. This is well so far as it goes, for people cannot sit down if they have no seats; but it does not follow that they will sit down when the seats are there. Let anyone observe as they enter our great emporiums how many shop assistants will be seen occupying the seats which the law insists must be provided. "Nothing succeeds like success," and the shopkeeper thinks that he will lose custom if he does not pretend to be very busy and successful. But if his shop assistants are seen sitting down it does not look as if they were very busy and therefore they must stand up and pretend to be busy even when there is nothing to do. The shopwalker is there ever pacing up and down. He does not sit down himself and is not perhaps particularly inclined to favour others who endeavour to secure a little rest. What can be done in this direction has been done voluntarily by good and considerate employers. The mere providing of seats does not in any way force the other employers to follow this example. Even if they did it is doubtful whether this would suffice. After all a shop assistant must stand up to serve the purchasers. Even the purchasers, as often as not, also stand up. The only really radical cure is to shorten the hours for shopping.

In these circumstances the Bill which Lord Avebury introduced into the House of Lords and which has now been printed by order of the House of Commons deserves careful consideration. In so far as it will contribute to shorten the hours of labour for shop assistants this measure is welcome. The phraseology of the Bill does not, however, indicate that the question at issue is approached from this point of view. A good deal has been said of late concerning the alleged physical degeneration of the race. There is no evidence to show that the "occupiers" of shops are physically degenerate. The term seems to imply the owner of a shop or his principal representative. In any case the "occupiers" only represent an insignificant minority of the population concerned and they are perfectly at liberty to sit down, to take holidays, and, in fact, to do whatever may be the most conducive to the preservation of their health. On the other hand, the great majority of those concerned enjoy no such freedom. Compelled by their poverty to accept employment at almost any terms they are subjected to a very severe discipline, have to remain on their feet for so many hours that the gravest physical injuries result, and to cope against such consequences they receive but a poor wage. By far the easiest means of mitigating these evils is to do for the shop assistants what has been done for children and women employed in factories—namely, to limit by law the hours of labour. A law to that effect is needed and this is the opinion generally held by all who have studied the question. The Bill before the House of Commons only proposes that this should be done in those localities where two-thirds of the "occupiers" of shops petition the local authority to enact a by-law to that effect. Surely if the limiting of the hours cannot be enacted without holding first a consultation with the trade concerned the persons to be consulted are those who suffer and who constitute the immense majority of the people affected. If there is to be a referendum on a question which so clearly affects the health of a large section of the population it is that section of the population in its entirety which should vote. The matter concerns the employers it is true but it concerns the employed very much more. The sale of goods must remain the same, whether the shops are open an hour or two more or less, for those trades that would be affected by earlier closing are excluded from the scope of the Bill, such as places for refreshment and for the sale of tobacco and newsagents. If, therefore, the same amount of business is done the "occupier's" main interest is secured, but to the people employed it is very important that their hours of work should not be so prolonged as seriously to endanger their health. The shortening of these hours is a matter of national concern. It is to the nation's interest, especially after recent disclosures that have rendered the danger of physical degeneration so evident, that the hours of work in the shops should be reduced. The nation therefore should decide upon this question instead of meekly waiting till the two-thirds of the "occupiers" shall in each district take the trouble to move in the matter. Under such a law years may elapse before this urgent reform is widely applied. Lord Avebury's Bill has been described as "a master's Bill" and what is wanted is a national measure instead of class legislation. Considering the large number of persons employed in the retail trade it is to the interest of the nation that the work of the shop assistants should be so regulated as to prevent its producing serious injury to their health.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Royal Southern Hospital: The Tropical Diseases Ward.

THE committee in its annual report to the subscribers stated that in July last it was so seriously impressed by the financial position of the hospital that it considered it necessary to make a special appeal for donations and increased subscriptions. Although the result did not realise the expectations of the committee the sum of £1529 16*s*. was received and new and increased subscriptions were promised to the extent of £110 In spite of this assistance the adverse balance on Dec. 31st, 1903 due to the bank amounted to £5325 2*s* 6*d*. Mr. John W. Hughes has generously contributed £300 for enlarging, improving, and lighting with electricity the x ray rooms, which would now make the department one of the most complete in the kingdom. The tropical diseases ward continues to justify its existence by the number and importance of the cases treated. During 1903 the patients were 149, as against 137 and 131 in the previous years. Year by year, therefore, testimony was afforded by this steady increase in numbers to the estimation in which it was held by those who entered the port in ships coming from tropical countries. As usual, the great bulk of these patients were suffering from malarial diseases alone or with serious complications. Other affections included dysentery, beri-beri, enteric fever, abscess of the liver, blackwater fever, bilharzia disease, craw-craw, sleeping sickness, enlarged spleen, &c. There were seven deaths. The nationalities represented were as follows: English, Irish, Scotch, Welsh, Manx, American, Canadian, South African, Indian, Chilian, Spanish, Portuguese, German, Austrian, Finn, Swedish, and Norwegian. There was also a constantly-growing number of students of the tropical diseases school in attendance. Those gentlemen were of many nationalities. It was probable that the institution of a diploma in tropical medicine contemplated by the University of Liverpool would still further attract students.

The Hospital Sunday Fund.

The amounts received representing the collections taken in the various places of worship on Jan. 10th show a falling off to the extent of £215, as compared with last year, but this adverse balance is lightened by the receipt of collections from new sources, which give a welcome lift of £75, so that up to date there is a net deficiency of about £140.

Civic Grant to the University of Liverpool.

At the monthly meeting of the city council held on Feb. 3rd it was unanimously resolved that a grant of £10,000 should be made during the current year to the University of Liverpool, to be paid out of the city rate and to be subject to the conditions that the council should nominate from time to time some person to make an inspection of the University and to report how far the methods employed were in the interests of the city and met its requirements; that the University should make an annual report in November to the council of its work, including a statement of accounts, particularly with regard to the amount voted by the city council, and that the city controller should inspect the same; also that of the sum of £10,000 not less than £1000 should be devoted to Liverpool scholarships, including the assistance of undergraduates and post graduates in the remission of fees in needy cases The grant was based on a contribution of £5300 to the sustentation fund, £1000 for scholarships, and the remainder towards the establishment of two new chairs—one of English literature and the other of French. The grant of £10,000 was not an annual grant but no doubt it would be continued if the council should be satisfied as regards the expenditure and the expected benefits to the city. The grant would stimulate rather than discourage the munificence of wealthy citizens, inasmuch as the question of maintenance would be made easier.

Sleeping Sickness at Uganda.

[illegible] panosomes and Sleeping [illegible] in the zoology theatre of [illegible] 12th by Colonel David Bruce, F.R S, R A.M.C., under the auspices of the Liverpool Biological Society. Professor Herdman presided over a good attendance. Colonel Bruce described how the trypanosomes, which are exceedingly minute blood organisms belonging to the lowest class of animal life, were first discovered in animals in India in 1877 and were spread by means of the tsetse fly, and the fact was then established that they set up sleeping sickness. Last year he was sent out as a commissioner by the Royal Society to Uganda for the purpose of studying the disease. The latter ran a course of from two to three years, sometimes more. For the first year or 18 months a man would apparently be free from illness and very often the disease would make itself known by undue signs of exultation on the part of the patient who instead of sleeping would be very much awake. The next stage would be depression and querulousness and it was in the last stage that the real symptoms would declare themselves. The sufferer would then lie about all day and would not get up even to feed himself. The disease attacked the brain, hence the lethargic condition The trypanosomes were found not only in the cerebro-spinal fluid, but also in the circulating blood of the natives who were examined by him. Every case of sleeping sickness died; more than 100,000 natives of Uganda had died from it and some parts of the country had become quite depopulated. The disease was almost absolutely confined to the shore of Lake Victoria and the islands, and it was only in those parts where there were lofty forest trees and thick undergrowth on the edge of the water that the tsetse flies were found.

Feb. 16th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

THE sixty-seventh annual report of the board of management of the Cardiff Infirmary is a much more satisfactory document than many of its predecessors. Until three or four years ago the institution was often in difficulties. The expenditure frequently exceeded the available income so that invested funds had to be realised and it seemed well-nigh impossible to obtain much-needed improvements and additions to the buildings. For some reason or other the working classes of the town were not very large contributors to the funds although the institution was well supported by the principal inhabitants and by the colliers and workmen in the surrounding districts. All this is now altered and in 1903 one-third [illegible] king people. [illegible] the year's wor[illegible] 1.806. There we[illegible] and 18,381 out[illegible] and 2323 respectively. The average cost per occupied bed in 1903 was £65 and in 1902 it was £63. There is accommodation in the infirmary for 180 patients but the funds available will only admit of 154 beds being constantly used. In February, 1902, the board of management issued a supplementary report setting out in some detail certain requirements which were urgently needed to make the infirmary thoroughly efficient. The cost of each addition or improvement was definitely stated and in several instances the precise sum has been given by a donor for a specific purpose. In this way during the past two years no less a sum than £13,500 has been expended and the managers have very little more to ask for. The latest additions include an electrical pavilion, in which there is a waiting room; a room for photography, including a dark room for developing ordinary and x-ray photographic plates; an x-ray room; a room for high-frequency treatment, galvanisation, faradisation, and massage by electromotor; and a lupus room fitted with two Finsen lamps and an x-ray apparatus. Connected with this room is a dressing room. The cost of the pavilion, £1450, has been defrayed anonymously by a lady but £500 are still required for the appliances.

Wells Cottage Hospital.

The Cottage Hospital at Wells (Somerset), which was established in the year 1875 and has now accommodation for 13 patients, continues to be a most useful institution, and although the demands upon its accommodation are increasing there is a corresponding increase in the financial support given to the board of management. In 1902 there were treated in the wards 38 patients, while in 1903 this number had increased to 48. In 1901 there was an adverse balance on the year's working of £25, in 1902 there was a balance on the right side of £9, and last year the expenditure almost exactly equalled the income, thus showing that the administration of the hospital is in capable hands.

Action for Damages against a Surgeon.

An action for damages was brought at Newnham county court in January last against a surgeon, for alleged neglect while attending a boy, ten years of age. According to the newspaper reports the boy fell from a ladder in August of last year and dislocated his elbow and fractured his forearm. For two months he was under the care of the surgeon who declared at the end of that time that the arm was right. A week or more subsequently the boy was taken to two other practitioners who said that there was still a dislocation. The defence to the action was that some improper treatment or some accident must have occurred to the arm after the defendant had last seen it.

The county court judge, however, gave judgment for the plaintiff for £16. The amount claimed was £30.

Death of Mr. Edmund Samuel Warburton, M.R.C.S. Eng., L.S.A.

The medical practitioners of the Rhondda valleys have lost a valued colleague and the colliers a trusted friend and a skilled surgeon through the death on Feb. 6th of Mr. E. S. Warburton of Treherbert. He was born nearly 60 years ago in Cheshire and came of a family of medical men. After making several voyages as a ship's surgeon he settled in Treherbert in 1874, when the Rhondda valleys were beginning to be developed, and was appointed surgeon to several large collieries. He was a very able diagnostician and a most capable operator. Although educated in an older school he was always abreast of the times and ready to give his patients the advantages of the newest remedies; for example, when diphtheria was epidemic in the district a few years ago he was one of the first to recognise the value of the antitoxin treatment.

Bristol Eye Hospital.

The annual meeting of the subscribers to this institution was held on Feb. 8th under the presidency of the Lord Mayor. The annual report stated that during 1903 the in-patients numbered 486, being 21 in excess of those for 1902. The out-patients were 6869, being an increase of 915 compared with the previous year. The financial statement showed that the subscriptions received amounted to £660 and that an unfavourable balance of £593 remained.

Taunton and Somerset Hospital.

The annual meeting of the subscribers to this hospital was held on Feb. 11th. The report showed that 813 in-patients were admitted during 1903, against 824 in 1902; the out-patients numbered 4739, compared with 3968 in the previous year. The average daily number of in-patients was 77. The financial statement showed that the income was £5068 and the expenditure was £5190. The appeal issued by the committee for £4000 for alterations and improvements to the institution has up to the present realised £2407. The report alluded to the regret felt by the committee at the death of Mr. Samuel Farrant who for 30 years was an honorary surgeon to the hospital.

Feb. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Aberdeen University Medical Society.

THE last meeting for the winter session of this society was held on Feb. 12th, Dr. George Stoddart presiding, Dr. Hugh Maclean read a most interesting paper on Some Points in Cardiac Diagnosis. When a dilated ventricle was observed, aortic incompetence should always be suspected and confirmation in other ways sought for. A water-hammer pulse was but a rare sign in aortic incompetence, because this was generally accompanied by some mitral regurgitation which served to keep up the blood pressure. It was the best [illegible] gnosing cardiac troubles previously to [illegible] other than the stethoscope all the abnormalities that could be so determined, and then to use the stethoscope to check or to confirm the diagnosis. Though of great use the stethoscope was not the only or the most valuable means of arriving at a correct diagnosis. An interesting discussion followed and on the motion of Dr. Stoddart, Dr. Maclean was accorded a vote of thanks for his paper. Office-bearers for the ensuing session were then elected.

Kingseat Asylum.

At Kingseat there will be opened in a week or two the first villa or segregate asylum, not only in Scotland but in Great Britain. The idea of a villa asylum—a most rational one—was brought to this country by Sir John Sibbald after a recent visit to the continent, and Aberdeen has been the first to teach the lesson of Alt Scherbitz, near Leipsic, so that Kingseat Asylum will now be the Mecca of alienists for some years. It is at present almost ready to open its villa and hospital doors to 472 patients and when completed some years hence it will accommodate 700. One of the remarkable features of this asylum is the economical cost of construction, affording as it does an object-lesson to every asylum board in Scotland. The following is taken from a statement by Mr. A. Marshall Mackenzie, [illegible] the asylum.

Comparative Cost of Glasgow, Lanark, Govan, and [illegible] Asylums per Bed available for Patients immediately after Completion.

	Price per bed for buildings [illegible]			Price per bed of cost of scheme, including land, buildings, and f[illegible]		
	£	s.	d.	£	s.	d.
Glasgow	[illegible]	7	2	[illegible]	6	0
Lanark	304	17	1	348	5	[illegible]
Govan	392	3	1	461	19	0
Aberdeen (Kingseat)	208	15	2	253	10	1

The above represents more than the true cost per bed of the asylum at Kingseat when completed, as meantime the general blocks, including laundry and power house, steam boilers, &c., electric and cables, kitche[illegible] lodges, medical [illegible] sewage works, an[illegible] to an asylum wi[illegible] future increased [illegible] additional villa buildings and furniture. Having in the [illegible] the cost of all buildings separate, I am able [illegible] of villas and find that to accommodate the [illegible] of £26,817 10s. would be required for build[illegible] reduces the cost per bed o[illegible] accommodate 700 patien[illegible] £200 19s. 2d. for the total [illegible] General Boar[illegible] economically [illegible]

There is the greatest c[illegible] view between what we have been accustomed to look [illegible] and this new villa asylum. The days of vast and [illegible] piles of buildings are over and if asylums ever [illegible] required no longer any householder wishing to live a [illegible] country life can purchase a villa. The buildings can never be lost, like many of our public institutions, tier above [illegible] and stretching in one line for hundreds of yards, [illegible] rectangular blocks jutting out on both sides. [illegible] if the hard headed Aberdonian claims it to be the best [illegible] cheapest asylum in the world.

Appointment of Medical Superintendent of Inverness Asylum.

At a meeting of the Inverness district lunacy board on Feb. 12th, Major Stirling presiding, Dr. Robert [illegible] Campbell of the Crichton Royal Institution, [illegible] was appointed medical superintendent of the [illegible] District Asylum in room of Dr. J. Keay, who has received the appointment of medical superintendent [illegible] the Bangour Asylum, Edinburgh. Dr. Campbell was [illegible] short time in general practice after graduation but [illegible] 1896 he has devoted himself exclusively to the study [illegible] treatment of insanity. He was assistant physician at [illegible] Inverness Asylum in 1896, then senior assistant at the Montrose Royal Asylum, and latterly at Dumfries. The salary of the new appointment amounts to £500, with [illegible] house, fire, and light.

Changes at the Royal Infirmary, Aberdeen.

Dr. J. Mackenzie Booth has resigned owing to [illegible] and intends to leave soon for Egypt. Dr. J. Scott [illegible] has succeeded consequently to No. 2 ward, while [illegible] H. M. W. Gray has been appointed to No. 1 ward.

Feb 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Legal Action for Personal Injury caused by the Use of the [illegible] Röntgen Rays.

A CASE of much medico-legal interest has recently been tried in Dublin before Mr. Justice Gibson and a special [illegible] The action of McCullagh v. The President and Professors [illegible] the Queen's College, Galway, William Blaire, and [illegible] Colahan was commenced on Feb. 4th, when the [illegible] a child, suing through his father, sought to recover [illegible] for personal injuries caused by the alleged negligence of [illegible] defendants in the use of certain electrical [illegible]

Mr. O'Shaughnessy, K.C., opened the case for the plaintiff and described the manner in which the child—who is between seven and eight years of age—was subjected to the Roentgen rays for the purpose of searching for a needle which was supposed to have penetrated his knee. Counsel said that the child was subjected for 20 minutes to the Roentgen rays, under the supervision of Dr. Colahan, the radiograph having been taken by the defendant Haire. Whether the instrument was out of order or whether those who used it did not know how to use it properly no result was achieved. Counsel stated that during the operation the vacuum tube, instead of being kept away from the leg was within two or three inches of it and the boy was subjected to the rays twice. Two of the operations took place on Dec. 26th, 1902, and as a result of these the boy suffered great pain. When the bandage was removed on Dec. 29th it was seen that the leg was burned. During succeeding days it became worse and the boy was taken to hospital. In the month of April, when he was better and out of hospital, Dr. Colahan ordered the patient to be subjected to the rays and he was taken to the College and the rays were applied. Finally, his mother, on account of the pain the child was suffering, took him to Dublin where he was seen—as counsel stated—by Mr. J. S. McArdle who sent him to Mr. Lewis to be subjected to the rays. Mr Lewis, seeing that the leg was burnt, declined to apply the apparatus. The plaintiff's mother then took him to Dr. J. Lentaigne who would tell the jury that the child had been burnt by the Roentgen rays. Many witnesses were examined for the plaintiff including Dr. W. S. Haughton, demonstrator of x rays in Trinity College, who said that the ordinary working distance of an x-ray apparatus was from 12 to 24 inches. Dr. Lentaigne said that when the case was admitted to the Mater Misericordiæ Hospital there was an ulcerated patch four inches by three and a half inches on the inside of the knee. Mr. Henry, K.C., in his address on behalf of Dr. Colahan, said that it would be impossible for the radiograph of April 22nd to have been taken if the globe were held within two inches of the limb and that they intended to produce x-ray experts from England On Feb. 9th Dr. H. Lewis Jones, medical officer in charge of the electrical department of St. Bartholomew's Hospital, London, Mr. J. Hall Edwards, surgeon in charge of the x-ray department at the Royal Orthopædic Hospital, Birmingham, Sir Charles B. Ball, Sir Thornley Stoker, Mr. McArdle, and other witnesses were examined for the defence, their evidence tending to show the rarity of injury by the application of the Roentgen rays, the absence of any indication of improper use of the apparatus in the radiographs produced, and generally to disprove the story of the plaintiff's witnesses as to the manner in which the rays were applied. Several questions were left by the learned judge to the jury who found that the sore complained of was caused by the rays but that the Queen's College had no responsibility in the matter. With regard to Mr. Haire, the mechanical assistant to the Professor of Natural Philosophy at the College, and Dr. Colahan, both of whom had taken radiographs of the child's knee, they found that each had by what he had done contributed to the condition of the child's knee but absolved both alike from any charge of negligence in the matter, the net result being a verdict and judgment for all the defendants upon the various issues raised.

Royal College of Surgeons in Ireland.

The annual dinner of the Royal College of Surgeons in Ireland was held in the College on Feb. 13th, under the presidency of Sir Lambert H. Ormsby. The occasion was honoured by the presence of the Lord Lieutenant.

Londonderry City and County Infirmary.

An influential deputation appeared before the Londonderry county council on Feb. 11th to request a contribution towards the payment of improvements recently carried out in connexion with this institution. A sum of £3120 2*s.* has been received from private subscriptions. According to the Local Government Act, one-third of this amount could be subscribed [illegible] rough of Londonderr [illegible] 17*s* 2*d*. and the co [illegible] has been referred to [illegible] ncil and there is a strong feeling in favour of granting the request.

The Belfast Water-supply.

At a meeting of the Belfast Water Commissioners, held on Feb. 11th, the chairman mentioned that since September, 1901, the Mourne water has been brought from the Annalong [illegible] ly of from 3,000,000 to [illegible] of the first section of [illegible] ing order and in addition the short length of the main conduit which lay between the Kilkeel and Annalong valleys was now complete and capable of bringing the water from the Kilkeel river. By this tunnel water will be brought a distance of 40 miles to Belfast. In reply to queries as to whether there was any truth in the statement that there was something wrong in the scheme for a reservoir in what is known as the Silent Valley in the Mourne Mountains it was stated that it was now beyond any question of doubt that this reservoir embankment could be completed in a slightly altered line at less cost than was originally estimated. At present there was an ample supply of water for the city of Belfast and so the new reservoir at the Silent Valley would not be required, but when needed it could easily be constructed.

County Down Infirmary.

During the past year 505 patients were admitted to this infirmary, being 103 in excess of the previous year, and in addition there were 37 who were in the hospital on Jan. 1st, 1903. There were 845 extern cases. Open air shelters are needed for the tuberculous patients, who form 15 4 per cent. of the total annual admissions, and better accommodation is asked for the extern cases. The total income for the year 1903 was £1910 2*s* 7*d*, exceeding the expenditure by £210 7*s*. 3*d*., but as £100 of this is a special grant from the county council for the introduction of a water-supply the actual balance towards the revenue account of the infirmary is £110 7*s*. 3*d*. The average number of beds daily occupied was 38.

Feb. 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Information Bureau of the University of Paris.

ON Feb. 10th the official opening of the Information Bureau of the University of Paris took place. The opportunity was taken for an official visit of the committee of the municipal council of Paris and of the council of the University, the two forming one grand committee to be known under the name of the Conjoint Committee for the common interests of the City of Paris and of the University. The Vice-Rector of the University, M. Liard, is president. Numerous press representatives, both French and foreign, were present at the opening, at which there was the usual interchange of ceremonious speeches between the Vice-Rector and M. Dausset, the president of the fourth committee of the municipal council. As a matter of fact, the bureau has been in working order since August, 1903, and I have previously given your readers an account of it,[1] for it will certainly be capable of rendering great service to foreign travellers and men of science and letters. The offices of the bureau are in a magnificent room in the Palace of the Sorbonne and are luxuriously furnished and decorated. Here are to be found employés speaking French, English, German, Spanish, and Russian, together with every information necessary for those seeking opportunities for studying in Paris. The information is all classified, so that anyone who wishes to study any particular question will find all books and documents which are able to help him with regard to lectures, conferences, museums, libraries, societies, journals, and the like. Information is also kept as to the hours of opening of museums and libraries and the conditions governing admission, while a large map of Paris is available to show the stranger his way. The bureau is on the telephone exchange and is under the general direction of Dr. Blondel, the general secretary of the International Association of the Medical Press. The advantages which this institution will offer to the large number of strangers who come yearly to Paris to avail themselves of the sources of information which that city possesses to so great a degree are obvious and it already has some 3000 indexed catalogues of subjects. Hitherto the multiplicity of catalogues, indices, calendars, and the like, the multiplication of places for obtaining information and their distance the one from the other, together with the difficulty which the stranger not well acquainted with the language experienced in obtaining information, often discouraged him. Since the bureau commenced operations many hundreds of English medical men and students of medicine have availed themselves of its services and have expressed themselves delighted at the help so given.

---

[1] THE LANCET, Jan. 17th, 1903, p. 207.

Opposition to a Sanatorium for Tuberculous Patients.

I have already mentioned that the Assistance Publique in Paris had decided to establish a model sanatorium for tuberculous patients at Montmorency on ground belonging to the Duc de Dino, admirably situated from the hygienic point of view. All the preliminaries were completed and everything was in readiness for commencing work when about 100 property owners in Montmorency and the adjoining communes took united action under the presidency of the senator for Seine-et-Oise to oppose the institution, alleging that it would be the ruin of Montmorency and the neighbourhood. Such hostility is very annoying and behaviour of this kind betrays inability to understand the true interests of France. It is impossible for a great city to accommodate all its hospital institutions within the municipal boundary, especially a hospital for the isolation of tuberculous patients. It was difficult enough to persuade the Government that an important means of preventing the disease consisted in isolating the patients instead of allowing them to die in the general hospitals where they become foci of infection; it is therefore to be hoped that the progress which is being made in the right direction may not be checked by claims put forward on behalf of private interests.

Yoghourt.

At the meeting of the Academy of Medicine held on Feb. 2nd M. Saint-Yves-Ménard read for M. Dybowski of Adabazar in Asiatic Turkey an interesting communication on a preparation derived from milk and called yoghourt. In Turkey there is a great consumption of the milk of the buffalo, the common cow, the goat, and the ewe, but it is hardly ever used in the natural state. It is kept at a moderate heat—about 80° C. or 176° F.—until its bulk is reduced to one half, and after gradual cooling it is treated with a ferment taken from the previous day's supply. In some hours a curd forms which is called yoghourt. It is said to have a pleasant taste and forms together with bread the principal part of the food of the rural population. This preparation is preferred to milk. It not only has the nutritive value of the latter in a small bulk but it also possesses a diuretic property which is very useful in heart disease, in dropsy, and in the eclampsia of pregnancy.

Feb. 15th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Battle of the Clubs.

A CONGRESS of the German sick clubs was held at Leipsic on Jan. 25th for the purpose of discussing the measures to be taken in opposition to the demands of the medical profession. As already described in THE LANCET, membership of a sick club is compulsory under the Workmen's Insurance Act in Germany, so that the clubs have an enormous number of members, and the medical profession, especially in the industrial towns and districts, is largely dependent on the goodwill of the club committees. The fees paid in club practice are extremely low and, what is still worse, only a limited number of medical officers are appointed. In some places such positions can be obtained only by practitioners who are either acquainted with members of the committee or are known to belong to the Socialist party. Some years ago, first in Berlin and afterwards in other towns, the so-called "free-choice" movement began in the profession, its object being to admit every medical practitioner of a locality to club practice provided that he was willing to accept the club fees; the clubs had to pay a certain annual sum for every member and the aggregate proceeds were eventually divided among the various practitioners according to the number of consultations, visits, operations, &c., which had fallen to the share of each. In course of time the movement spread throughout Germany and though it worked quite satisfactorily in a good many clubs it was nevertheless strongly opposed not only by other clubs but also by certain medical men who, as club officers appointed at fixed salaries, were afraid of losing a considerable part of their income by the introduction of the "free-choice" system. A few years ago the encroachments of the clubs were resisted only by local organisations of the medical profession, so that in the case of a difference between the club and the local profession the club had only to appoint medical men coming from other places who were anxious to engage in practice and were therefore willing to accept any fee, even the lowest, offered to them by the clubs. Recently, however, a general association was founded at Leipsic, the so-called Leipziger Verband, for the purpose of organising resistance on a larger scale. The Leipziger Verband is in connexion with the [illegible] Deutsche [illegible] those of th[illegible] and in cer[illegible] It has loc[illegible] arises betw[illegible] first tried, [illegible] proclaimed [illegible] medical a[illegible] settling in [illegible] practitione[illegible] by a club [illegible] leave the [illegible] happened at C[illegible] in a strike [illegible] the "free[illegible] augmentat[illegible] of the club[illegible] to act a[illegible] 150,000 m[illegible] medical a[illegible] quite unsa[illegible] powers of [illegible] certain ex[illegible] latter int[illegible] provide w[illegible] men, the alternative being that in case of default the Government in exercise of the power conferred on it by the law would dissolve the [illegible] would have the clubs managed by a Govern[illegible] clubs accordingly were forced to [illegible] the profession and to comply with [illegible] branch of the Leipziger Verband [illegible] off the 20 newly appointed medic[illegible] medical service of the clubs. [illegible] the profession, not only at Colog[illegible] wise, and due principally to the e[illegible] on a large scale, have greatly excited the leaders of the workmen's sick clubs who h[illegible] view to defeat the policy c[illegible] held at Leipsic was there [illegible] a good many of the large [illegible] explained that the unsa[illegible] profession was not due to the club[illegible] overcrowding of the profession and [illegible] clubs to their medical officers must [illegible] employers to employed, the clubs, t[illegible] charitable institutions. The "free c[illegible] opposed as a matter of principle, [illegible] take place by common agreement [illegible] medical trade union or by legislatio[illegible] "free-choice" system from the sta[illegible] according to the report, that unde[illegible] but also the cost of medicine and [illegible] an enormous degree. The report [illegible] tion enacting that in the event of a medical strike the medical men should be obliged to attend provisionally the club members at a fixed rate until the matter was settled, so that a strike would be practically rendered illegal. After a long and animated discussion, in which also delegates of clubs adopting the "free-choice" system spoke, the congress passed a resolution to the effect that the introduction of the "free-choice" system by legislation or by a medical trade union was undesirable and that any intervention of the authorities, as in Cologne, was deserving of censure.

The Preservation of Milk.

Professor von Behring, whose views on the origin of tuberculosis are well known, has recently directed his attention to methods of artificial feeding and the preservation of milk. In an article published in the *Therapie der Gegenwart* he says that fresh milk taken from a cow under every possible precaution against contamination contained at least from 100 to 200 germs in every cubic centimetre. Milk taken by the usual method contained many thousand germs per cubic centimetre In order to avoid chemical alteration of milk he recommended not sterilisation by boiling but the addition of formalin One gramme of this substance (a quantity too minute to be tasted at all) was sufficient to preserve 4000 grammes of milk for eight days In a large farm where many newly born calves died within 48 hours from an epidemic termed "Kälbersterbe" artificial feeding of the calves on milk containing formalin had the effect of making the mortality at once decrease Professor von Behring has also obtained experimental results which are important with respect to tuberculosis According to the views explained by him at the Medical Congress in Cassel tuberculosis arose in the early days of life and was conveyed by the milk through the intestinal wall of infants He has also ascertained that milk from cows which were immunised against tuberculosis contained certain substances highly antitoxic against tuberculosis Bacterium coli might be advantageously used in the study of the antitoxins of milk When a quantity of these bacteria were added to milk yielded by immunised cows the number of germs decreased from 700 000 to 4000 within 24 hours and to 200 within 48 hours, but by previously boiling the milk for one hour the antitoxic substances were destroyed and even the action of formalin was neutralised Veterinary surgeons were already aware that the enteritis of calves caused by the bacterium coli might be avoided by feeding them with fresh cows' milk, whilst the administration of sterilised milk produced fatal diarrhœa Professor von Behring was of opinion that the great mortality of infants might also be due to the administration of sterilised milk The best nourishment was, of course, the milk from the mother, but when this was not available genuine unsterilised cows' milk should be used He hoped to be able to produce a milk free from the germs of tuberculosis, the cows being immunised at an early date by preventive injections By addition of formalin the milk might be preserved and made fit for transport The attention of the Government has evidently been directed to Professor von Behring's proposals as during his last visit to Berlin he had an interview with the sanitary authorities

Feb 15th

Obituary.

HENRY ROBINSON, L R C P, L R C S EDIN

BY the death of Mr Henry Robinson the medical profession in Chesterfield loses its doyen and an interesting link between the immediate past and the present is broken He was born in Chesterfield where the family to which he belonged was well known and highly respected At the time when he chose medicine for his profession it was still the custom to enter it by the way of apprenticeship He accordingly became apprentice to Dr Holland and after his death to his successor, Dr Charles Booth, who subsequently became Mr Robinson's brother in law At a later period he passed to the wider sphere of the University of Edinburgh but as domestic causes unfortunately hindered him from graduating in the University he took the qualifications of L R C S and L R C P Edin in 1863 and returned to his native town, where his professional ability, his gentle and pleasing personality, and his family connexions speedily secured to him a busy and lucrative practice Despite the cares this incurred he yet found time for occasional contributions to medical literature A case of Pregnancy with a Perfect Hymen was described by him in THE LANCET of August 7th, 1869 p 223, and he was one of the first to call attention to laburnum poisoning in a communication to the *British Medical Journal* in 1883 As for local medical records he was a perfect mine of wealth and his recollections were always at the service of his younger brethren, in spite of the fact that during his later years his impaired health enforced on him an almost complete retirement

GEORGE HADDOW, M B, CH B EDIN, D P H CANTAB

Dr George Haddow, whose death at the age of 29 years occurred recently in the Royal Infirmary, Glasgow, was the eldest son of Mr. James Haddow, Springbank, Falkirk, and studied medicine at Edinburgh University, where he graduated with first class honours After a voyage round the world as medical officer on board the s s *Rakaia*, belonging to the New Zealand Steam Navigation Co, he took the diploma of D P H Cantab and settled down to practice in the Shettleston district of Glasgow about eighteen months ago Of a genial and warm hearted disposition Dr Haddow soon gained the esteem and affection of his colleagues and the people of Shettleston and the keen anxiety which was manifested by all classes during his illness bore eloquent testimony to the high place he had attained in their regard The funeral, which took place at Falkirk, was attended by a large and sympathetic gathering

Medical News.

UNIVERSITY OF CAMBRIDGE —At a Congregation on Feb 11th the following degrees were conferred —

Doctor of Medicine —J C S Rashleigh Trinity
Bachelor of Medicine —G T Birks Kings
Bachelor of Surgery —A Wylie Pembroke and E Bigg Gonville and Caius

In the Easter term the Final M B examination (medicine surgery, and midwifery) will begin on April 26th, the M C examination will begin on April 28th Candidates for either examination must send their names to the registrar by April 14th —The programme relating to the visit of the King and Queen to the University on March 1st has now been published by the Vice Chancellor The Vice Chancellor will meet their Majesties, who will be accompanied by H R H Princess Victoria at the Great Northern railway station and will conduct them to the Senate House Here the Queen and Princess Victoria will remain while the King will proceed to the University library to join the Chancellor's procession The Chancellor's procession will enter the Senate House for Congregation, after which their Majesties and Princess Victoria will proceed to the Fitzwilliam Museum for luncheon The first visit after luncheon will be to the medical school where the Regius Professor of Physic, the Downing Professor of Medicine, the Professor of Surgery, and the Professor of Pathology will receive their Majesties for the opening of the new medical school buildings Next will come an inspection of the new law school and of the new botanical laboratory and, lastly, their Majesties will proceed to the Sedgwick Museum and there unveil the statue of Professor Sedgwick Post cards to be filled up as applications for seats in the Senate House during the ceremony, will be sent to all members of the electoral roll Non resident Doctors of Medicine wishing to take part in the procession should apply to the Vice Chancellor, Queens' College Lodge, not later than to day (Saturday, Feb 20th) Doctors of Medicine will wear scarlet —The regulations for a new examination for a diploma in tropical medicine and hygiene were issued on Feb 13th Any person whose name is on the Medical Register is admissable as a candidate subject to certain conditions and fees All applications for information respecting the examination should be addressed to Mr G F H Nuttall, University Pathological Laboratory, Cambridge

TRINITY COLLEGE, DUBLIN —At examinations held in Hilary term the following candidates were successful —

Final in Medicine —Herbert St M Carter Arthur W Goldsmith Wright Mitchell Owen J Parry Edwards Henry M Crawford John C Hall Wilfrid Thunder, William J M Iver and David C Pearson
M B —Robert Moore

THE KILMARNOCK INFIRMARY —The total number of patients treated in this institution during the year ending Nov 11th, 1903, was 1273 a decrease of 55 compared with the previous year—viz, 335 fever patients, against 392, 390 medical, against 398, and 548 surgical, against 538 In addition, 167 out-patients were treated for accident and other troubles who did not require to remain in the hospital The average daily number resident in the various wards throughout the year was 106 compared with 118 in the previous year The total income for the year was £4742 4*s* 11*d*, being £339 1*s* 1*d* less than the income of the previous year, and the total expenditure was £5390 4*s* 2*d*, a decrease of £85 15*s* upon the past year.

The general subscriptions amounted to £789 14*s.*, being £19 16*s.* 9*d.* less than the previous year. The employés' subscriptions were £841 18*s.* 9*d.*, a decrease of £291 7*s.* 3*d.*; and the church contributions amounted to £271 15*s.* 9*d.*, an increase of £8 12*s.* 9*d.* The expenditure has exceeded the income by £647 19*s.* 3*d.*, and the loss in maintaining the institution during the past two years has amounted to nearly £1042.

Death of Dr D. R: Guns.—The untimely death is recorded of Dr. D. R. Guns, house surgeon to the Royal Infirmary, Newcastle-upon-Tyne. He was only 25 years of age, was qualified last September, and entered the infirmary as house surgeon about a fortnight ago. A few days since he developed double pneumonia and died on Feb. 13th. Although cut short at the very commencement of his professional career he had gained for himself a host of friends and had already given promise of a brilliant future.

Society of Arts.—At a meeting of this society, held on Feb. 10th, Professor C. Vernon Boys delivered an address on Thermit, at the same time showing a variety of lantern pictures, samples of thermit welding both rough and in section, and requisites for the process. Thermit is a mixture of aluminium and iron oxide; it has the appearance of small black elongated grains resembling short lengths of very slender "pencil lead" and not unlike the gunpowder used for sporting purposes. When ignited it produces a temperature of at least 3000° C. and therefore much above the melting point of platinum and the dissociation temperature of the products of the combustion of carbonaceous fuel. The combustion products of thermit are molten pure iron (not cast iron) and molten alumina, both of them at such a temperature that they will instantly melt a hole in boiler plate and run through it. Its ignition point is so high that ordinary combustibles have no effect on it and it is usually ignited by contact with a burning mixture of aluminium and peroxide of barium which can be easily set on fire with a match. Before being lighted the thermit is put into a crucible lined throughout to a depth of about an inch with magnesia.

Edinburgh University Graduates' Annual Dinner, Newcastle upon Tyne.—The second annual dinner of the Edinburgh University graduates was held in Newcastle-upon-Tyne on Feb 12th. Dr. Frederick Page, professor of surgery in the University of Durham, occupied the chair. The guest of the evening was Sir William Turner, K.C B., Principal of the University. About 55 sat down to dinner, amongst whom were Professor Sir G. H. Philipson, Professor R Howden, Professor T. Oliver, Dr. T. W. McDowall (Morpeth), Dr. David Ridpath (Sunderland), Dr. J. W. Smith, Dr. J. Limont, and Dr. J. S. McCracken. Dr. Smith submitted the toast of "Alma Mater" In a very interesting speech he traced the history of the Edinburgh University and College of Medicine since its inception and mentioned the names of many of its most distinguished alumni, especially Joseph Black, William Collin, James Gregory, Sir Douglas Maclagan, Thomas Locke, Sir Joseph Lister, and Sir James Simpson. He mentioned the fact that the two greatest blessings to humanity and the medical profession—chloroform and antiseptics—were both discovered by Edinburgh men. Sir William Turner also spoke and said that the University, notwithstanding its 300 years, had an extremely good constitution. It had a power of retaining its youth and of recuperating itself from time to time. It had a great history to live up to and those who were in office realised their responsibility. He spoke for his colleagues and for himself when he said that they intended, as far as human means allowed them, that the University should keep its place. In conclusion, Sir William Turner expressed the hope that their warm love for the old University would long continue. Professor Page proposed "Our Guest." He described Sir William Turner as one of the most distinguished anatomists in Europe and also as a teacher of unexampled experience and success. Responding, Sir William Turner said that if a man was to rise to any position as a teacher there must be sympathy between him and those whom he had to teach. He mentioned a curious fact connected with the anatomical chair of Edinburgh. It was founded in 1720 and up to the month of January last year there had only been five professors in the chair. He took that as an evidence of the healthiness of the occupation of a professor of anatomy. The concluding toast, "The Chairman," was proposed by Professor Howden and was duly responded to.

Medical Barrister.—Mr. Lewis Lewis, M.D. Durh., who formerly practised in Plymouth and in Brixton, was on Jan. 26th called to the Bar at the Middle Temple.

Sanitary Assurance Association.—The twenty-third annual meeting of the members of this association was held on Feb. 15th, at the offices, 5, Argyll-place, London, W., Mr. Andrew Stirling, the President, being in the chair. In the annual report the council expressed regret that the principle of the Sanitary Registration Bill, promoted by the association, had not yet received the sanction of Parliament. The income of the year was £202 15*s.* 7*d* which, after meeting all liabilities, left a balance in hand. The report was adopted on the motion of the President, seconded by Mr. Mark H. Judge, and the retiring members of the council, Mr. Walter Butler and Dr. E. F. Willoughby, were re-elected.

Manchester and Salford Skin Hospital—At the annual meeting of the supporters of this hospital, which was held on Feb. 2nd under the presidency of the Lord Mayor, a strong case was brought forward for more room. The attendances made last year by patients were 64,130, of which 29 948 were for "light" treatment, a considerable increase on the previous year. The patients were not only from the Manchester district but from places as remote as Aberystwyth, Colwyn Bay, Blackpool, Douglas, Huddersfield, Oswestry, and Windermere. The "light" treatment had been satisfactory; a number of cases of lupus and other tuberculous affections of the skin had been discharged cured. In addition to the use of the Finsen-Reyn lamp the staff recently began to work with radium; but, as Dr. H. A G. Brooke said, it was too early yet to speak of its action. He emphasised the need for more beds, saying that they could deal with the out-patients fairly well. Dr. R B. Wild also strongly urged the same plea. There are two beds for men, which provision "was not only inadequate but ludicrous," four for women, and none for children. They hoped to provide 30 beds in the new hospital which would enable them to admit all the acute cases. For the contemplated new hospital a sum of £35,000 is needed and as £25,271 have been provided it has been decided to begin to build immediately.

Lectures on Medical Jurisprudence.—On Feb. 11th Dr. F. J. Waldo, coroner of the City of London, delivered a lecture on Poisoning in its Medico-legal Aspects at the Old Hall, Lincoln's Inn. The chair was occupied by Judge Marten, K.C, as representative of the Council of Legal Education. It was pointed out that neither lawyers nor medical men had any universally accepted definition of the term "poison." It would be obviously incorrect to call vitriol a poison when thrown into another person's face with intent to commit bodily injury. On the other hand, if administered internally the vitriol would be considered a poison both by lawyers and by medical men. Powdered glass, again, formed an extremely ancient method of causing death by mixing it with food. For all that it was not a poison although it killed after internal administration. The "poison" must, in other words, not only be taken internally but must exert some kind of chemical action upon the tissues. The Sale of Poisons or Pharmacy Act, 1868, was discussed at length by the lecturer who pointed out various ways in which its scope of usefulness might be enlarged. He agreed with Dr. W. Wynn Westcott in recommending the addition of the strong mineral acids, ammonia, and certain other poisons to the scheduled list. The evidence of poisoning as produced in court was then considered. The simulation of various diseases by poisoning and *vice versâ* was described, as, for instance, the similarity of lockjaw and strychnine poisoning and the resemblance of slow arsenical or antimonial poisoning to typhoid fever. The important subject of the evidence of poisoning to be derived from an examination of the dead body was exhaustively dealt with. The limitations and the powers of chemical analysis were described. In the case of some powerful alkaloids the dose was so minute that it would be almost impossible to detect their presence. Fortunately, both clinical and moral evidence was often available in these cases. The lecture was followed with interest by a large audience. This special course of evening lectures, open alike to the public as well as to lawyers, follows those already given by Judge Willis, K.C., Mr. Fletcher Moulton, K.C, M.P., Mr. Birrell, K.C., M.P., Dr. Blake Odgers, K.C., Sir Harry Poland, K.C., and other eminent lawyers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Proposed Amendment of Medical Act, 1886.

GENERAL LAURIE's Bill to amend the Medical Act, 1886, is supported by Sir Walter Foster, Sir John B Tuke, Mr Rothschild, Sir Howard Vincent, Mr. Middlemore, and Sir Mancherjee Bhownaggree. The following memorandum is circulated with the text of the proposals "In order to facilitate the admission of colonially trained and registered medical men to practise in Great Britain and hold appointments in the imperial service the Act of 1886 provided for reciprocity between the mother country and such of the self governing colonies as might comply with certain conditions, but that Act expressly stipulates that when any colony had a provincial and a federal organisation such reciprocal arrangements should be entered into with the federal government and not the provincial In the case of Canada the British North America Act of 1867, enacted by the Imperial Parliament, expressly provides that education shall be entirely under the control of the provincial and not the federal governments, so that it is impossible to bring the Act of 1886 into force with Canada It is impracticable to amend the British North America Act of 1867 and to transfer the control of education to the federal authorities, and therefore it is the object of this Bill to amend the Medical Act of 1886, without in any way interfering with the principle and to enable reciprocal arrangements to be entered into either with the federal or provincial governments"

Registration of Nurses.

Dr. R Farquharson's Bill to regulate the qualification of trained nurses and to provide for their registration has been put down for nally for second reading on Monday It is backed by Mr Haldane, Sir Thomas Wrightson, Sir James Joicey, Sir John Tuke, Mr. H C Smith, Mr Munro Ferguson, Mr. Tennant, Mr. Black, Mr. Colston, Mr Eve, and Dr E C Thompson.

Lead Poisoning

Mr COGHILL asked the
total number of deaths in
earthenware trade and in
and whether he proposes
with regard to the trade of house painters and plumbers —Mr. AKERS DOUGLAS, in reply, said. The number of deaths from lead poisoning in the pottery trade in 1903 was three The trade of house

painters and plumbers does not come within the Factory Act and returns of deaths are not required to be made to the Home Office. It appears, however, from information supplied by the registrars of deaths that there were in the same year in the whole of the United Kingdom 39 cases in which the death of persons stated to be employed in this trade was attributed directly or indirectly to lead poisoning. I do not propose to introduce legislation this session with regard to this trade.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ACLAND, H. T. D., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Christchurch Hospital, New Zealand.

BELGRAVE, T. B., M.D. Edin., has been appointed Inspector of Pearl Fisheries at Sharks Bay, West Australia; also to be District Medical Officer and Public Vaccinator at Denham.

BENNION, J. M., M.B. Cantab., has been appointed Junior House Surgeon to the Radcliffe Infirmary, Oxford.

BERRY, ROBERT SAWERS, M.R.C.S., has been appointed Medical Officer of Southport, Queensland, Australia.

CURL, SYDNEY W., M.A., M.B. Cantab., M.R.C.P. Lond., has been appointed Pathologist and Bacteriologist to the North-Eastern Hospital for Children, Hackney-road.

EWART, D., M.B., B.S. Edin., F.R.C.S.E., has been appointed Certifying Surgeon under the Factory Act for the Chichester District of the county of Sussex.

FOSTER, C. W., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Radcliffe Infirmary, Oxford.

GARDNER, A., M.B., C.M. Edin., has been re-appointed Medical Officer of Health for the Kirbymoorside District of Ryedale, Yorkshire.

GIBSON, A. G., M.B., B.Ch. Oxon., has been appointed House Physician to the Radcliffe Infirmary, Oxford.

HOLLICK, HUBERT HARRY, M.R.C.S., L.R.C.P. Lond., has been appointed Acting Medical Officer for the Care of Lepers detained in the Lazaret at Stradbroke Island, Queensland, Australia, during the absence of the Medical Officer, and Acting Superintendent of the Institution for Inebriates at Dunwich during the absence of the Superintendent; also to be Acting Medical Superintendent of the Dunwich Benevolent Asylum during the absence of the Medical Superintendent.

IVENS, FRANCES, M.S. Lond., has been appointed Surgical Assistant to the New Hospital for Women.

MANNING, RICHARD BEATTIE, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Wells (Somerset) District Cottage Hospital.

MARSH, C. J., L.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Act for the Yeovil District of the county of Somerset.

MARSHALL, J. COLE, M.B., F.R.C.S. Eng., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

MORGAN, EDWARD H., M.R.C.S., has been appointed Officer of Health of Hamilton District, Tasmania.

PENNY, HENRY J., L.K.Q.C.P. Irel., has been appointed Officer of Health of St. Helena, Tasmania.

SNELL, SIDNEY H., M.D., B.S. Lond., has been appointed Assistant Anæsthetist to the Royal Ear Hospital, Soho.

WATSON, GEORGE, M.B., Ch.M. Edin., has been appointed Officer of Health of Burnie District, Tasmania.

WATSON, J. F., M.B., M.Ch. Melb., has been appointed Assistant Medical Superintendent of the Hospital for the Insane, Toowoomba, Queensland, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN, KINGSEAT ASYLUM.—Assistant Medical Officer. Salary £110 per annum, with board.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Physician. Also Assistant Surgeon.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, John Bright-street, Birmingham.—Clinical Assistant. Honorarium at rate of 52 guineas per annum.

BIRMINGHAM, GENERAL HOSPITAL.—Surgical Casualty Officer. Salary £50 per annum, non-resident.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100, with board, residence, and washing.

BURTON-UPON-TRENT, COUNTY BOROUGH OF.—Medical Officer of Health and Public Analyst. Salary £400 per annum.

CANCER HOSPITAL, Fulham-road, London, S.W.—Surgical Registrar. Honorarium £26 5s per annum.

CARMARTHEN, JOINT COUNTIES ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.

CHELTENHAM GENERAL HOSPITAL.—Junior House Surgeon, unmarried. Salary £[illegible] per annum, with board, lodging, and washing.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—Junior House Surgeon, single. Salary £[illegible] per annum, with board, lodging, and washing.

CROYDON GENERAL HOSPITAL.—Senior and Junior House Surgeons, unmarried. Salaries £105 and £60 respectively, with board, laundry, and residence.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary commencing £100 per annum, increasing to £120, with board, residence, attendance, and washing. Also Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

EAST INDIAN RAILWAY.—Assistant Medical Officer. Salary commencing at Rs.400 per mensem.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Surgeon for six months. Honorarium of £25, with board, residence, &c. Also Medical Officer for the Casualty Department for six months, renewable. Salary at rate of £100 per annum.

GESTO HOSPITAL, Isle of Skye.—Resident Medical Officer. Salary £200 per annum, with house, coals, light, and taxes.

GLASGOW ROYAL HOSPITAL FOR SICK CHILDREN.—Resident House Surgeon. Salary at rate of £50 per annum, with board and laundry.

GORDON HOSPITAL FOR FISTULA, &c., Vauxhall Bridge-road, S.W.—Honorary Anæsthetists.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale.—Resident Medical Officer for six months. Salary at rate of £50 a year, with board and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence.

HOSPITAL FOR WOMEN, Soho-square, London, W.—House Physician for six months. Salary £30.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—Honorary Assistant Physician.

LIVERPOOL CHILDREN'S INFIRMARY.—Assistant House Surgeon for six months. Salary £22 10s., with board and lodging.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary £60 per annum, with board, lodging, and washing.

ROCHESTER, ST. BARTHOLOMEW'S HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £100 per annum.

ROYAL PIMLICO DISPENSARY, 104, Buckingham Palace-road, S.W.—Attending Medical Officer.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, S.E.—Head Dispenser.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon for six months. Salary £[illegible] per annum, with board and residence.

ST. MARY'S HOSPITAL, Paddington, W.—Resident Casualty House Surgeon for six months. Salary £100 per annum, with board and lodging.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Honorary Dental Surgeon.

WEST BROMWICH DISTRICT HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith road, W.—House Physician and House Surgeon for six months. Board and lodging provided.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Fourth Assistant Medical Officer. Salary £150, rising to £180, with board, &c. Also Fifth Assistant Medical Officer. Salary £140, rising to £160, with board, &c.

WEST RIDING OF YORKSHIRE.—Bacteriologist and Assistant to County Medical Officer. Salary £250 per annum, rising to £400.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory Act at Hornsea in the county of York, at Aughnacloy in the county of Tyrone, at Falmouth in the county of Cornwall, and at Broughton Astley in the county of Leicester.

Births, Marriages, and Deaths.

BIRTHS.

O'LEARY.—On July 21st, 1903, at Glenelg, South Australia, the wife of A. P. Evelyn O'Leary, M.R.C.S. & R.C.P., of a daughter.

POCOCK.—On Jan. 17th, at Quetta, India, the wife of Major Herbert Innes Pocock, R.A.M.C., of a son.

MARRIAGES.

BRIDGE—DAVIS.—On Feb. 11th, at St. Matthew's Church, Ealing, John Crosthwaite Bridge, M.R.C.S., L.R.C.P., to Bessie Coleridge Davis, eldest daughter of the late Gateward Coleridge Davis, Barrister-at-Law, Inner Temple.

CAZENOVE—CRAWLEY.—On Feb. 13th, at All Souls Church, Leeds, William Reginald Cazenove, M.R.C.S., L.R.C.P. Lond., to Amy, younger daughter of Edward W. Crawley, of Leeds and Ilkley.

DEATHS.

HIND.—On Feb. 16th, at Blytheholme, Harrogate, Annie Charlotte, wife of Henry Hind, F.R.C.S.

MARVAL.—On Jan. 4th, at S. Catherine's Hospital, Cawnpur, U.P., Alice M. Marval, L.R.C.P.S. Ed., of pneumonic plague.

STARLING.—On Feb. 11th, at The Rowans, Brook-green, John Starling, M.R.C.S., L.R.C.P., in his 72nd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE OLD-FASHIONED APOTHECARY'S BILL.

IN another column will be seen some comments upon a copy of an apothecary's bill received from Dr. R. P. Smallwood of Little Waltham, near Chelmsford. By a coincidence during this same week we received from Mr. H. O. Huskisson, of 5, Gordon-square, W.C., a copy of an apothecary's bill rendered in 1806 by Mr. A. Robinson to an invalid—Mrs. Huskisson. From this bill it would seem that Mrs. Huskisson took a draught and a pill every day from Dec. 2nd, 1806, to the 19th, except upon the 14th. Upon the 6th she had a box of pills, whether of the same quality or not is not stated, and on the 7th she took an extra draught. In the seventeenth and eighteenth centuries it was evidently the medical man's medicine rather than his advice that was paid for and we doubt if public intelligence has got as far beyond this point as it should. There is still a widespread impression, not [illegible] of the community, that there [illegible] medical man unless you also [illegible] ts do not in the twentieth [illegible] ıgs on medical instruction as they did 200 years ago they swallow more upon their own initiative. Children may hate medicine but the world at large loves it, and now that the medical profession has become more chary in prescribing formulæ the enterprising druggist and the unscrupulous quack are prepared to fill the vacancy.

GARLIC AS A REMEDY.

To the Editors of THE LANCET.

SIRS,—Having read Dr. W. C. Minchin's interesting letter in THE LANCET of Feb. 13th, p. 481, upon the action of garlic in tuberculosis, it may interest some of your readers to know that garlic has been a remedy in common use for certain diseases in Wales for a great number of years; in fact, it is only one of a large number of herbs used by the natives, the therapeutical action and uses of which have been probably handed down from father to son since the days of the Druids who were the physicians as well as priests in their day and were good botanists. I inclose a recipe in Welsh with English translation taken out of a book compiled by Lewis Morris, formerly of Anglesey (Môn) and an ancestor of Sir Lewis Morris (author of the "Epic of Hades"). The book from which I take the extract is called "Rhodd Meistr i'w Brentis" ("The Master's Gift to his Apprentice"), published in 1812 by R. Jones at Dolgelly.

> "Rhag clefyd y garreg, neu garchar dwfr cymmer thyme, parsley, topiau ffenigl, a'r ddalen pum dalen, chwech neu saith o ewinedd *garlleg;* pwywch hwynt ynghyd, ac ystreiniwch i win gwyn, neu gwrw da; yfwch o hono bob nos a bore."
>
> *Translation of above.*
>
> For *the disease called gravel* (stone) or stoppage of water (stricture) take thyme, parsley, fennel tops, and the five-leaved leaf, and six or seven claws of garlic; powder them together and strain with white wine or good ale; let the patient drink of this night and morning.

In addition to the above, in another book published over 50 years ago by Daniel Evans, druggist, of Llandyssul, Ceredigion, I found the following, also in Welsh: "Garlic should be raised to dry in August. They are useful to remove flatulence."

In the first-named book there is also a recipe for a cough mixture which contains garlic, horehound, &c. Some years ago the juice of garlic mixed with whisky was a popular remedy for phthisis and quite recently I have heard it lauded as a cure for hysteria, probably on account of its strong odour.

I am, Sirs, yours faithfully,

Y. M. JONES-HUMPHREYS.

Cemmaes, Montgomeryshire, Feb. 15th, 1904.

PREHISTORIC THERAPEUTICS.

IN a recent number of the *Revue de l'Ecole d'Anthropologie de Paris* M. Manouvrier has dealt with certain markings which he and others have observed on neolithic skulls. The markings usually take the form of straight or T-shaped dotted lines apparently due to localised periosteal inflammation. It has been supposed that they may be connected with unknown ceremonial rites but the probabilities are in favour of their having rather a therapeutical interest. M. Manouvrier refers to statements which he has found in ancient surgical writings where it is laid down that "to regulate the humidity of the skull," upon which many maladies were thought to be dependent, the cautery should be lightly applied at numerous points in the occipital or the frontal region. He suggests that this use of the [illegible] and that the skulls [illegible] The skulls found mar[illegible] leads us to infer that primitive man adopted [illegible] methods of treating the attacks of headache or of the vapours from which the feminine members of his family suffered.

MR. BLANK OF PICCADILLY CIRCUS.

WE have received a copy of the *Barbados Advocate* wherein is an advertisement calling attention to the scientific claims of one, "G. Thomson Blank (late of Piccadilly-circus, London)," who is described in the heading as dental surgeon to His Excellency Sir Frederic Hodgson, K.C.M.G., Governor of Barbados, Lady Hodgson, and Miss Hodgson. The advertisement is the usual thing: the artificial teeth are the finest and most life-like, the treatment is [illegible] modern instruments and [illegible] the advertisement is, in [illegible] heading, and we admit that we are curious to know if Mr. Blank has authority for describing himself as dental surgeon to the Governor of Barbados—His Majesty's representative in our colony. If he has not the necessary authority he ought to be made to expunge the line from his advertisement. If the advertisement is in order Sir Frederic Hodgson, K.C.M.G., appears to us not to be a very prudent man.

RADIANT HEAT AND LIGHT TREATMENT.

To the Editors of THE LANCET.

SIRS,—For some little time past I have been suffering from gouty arthritis of both knees, both shoulders, elbows, and wrists and now contemplate trying the Dowsing radiant heat and light treatment.

Can any of your readers kindly answer the following questions? 1. Is it of any good in such cases? 2. Is there any danger in the treatment? 3 Is any special getting ready of the skin over the joints required? My joints have been painted with iodine and the skin is tender over them. 4. How many baths are usually taken? 5. After having had a bath are any extra precautions necessary to be taken to avoid chill? I am, Sirs, yours faithfully,

Feb. 13th, 1904. M.D. BRUX.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—There is one point in connexion with motor cars to which attention does not appear to have been called either in THE LANCET or in any other medical journal—viz., the risk of injury, of even severe injury, to the chauffeur in the act of starting. I have seen many cases myself. Usually it is a sprain of the wrist or a bruise or laceration of the back of the hand caused by a "back-fire." The wrist is sometimes actually fractured; but other parts, such as the face, may be cut; and the muscular efforts occasionally required to start a reluctant engine certainly sprain the lumbar muscles and, I am convinced, even the heart of not a few automobilists. It is chiefly in the case of single-cylinder engines that these accidents are frequent. But I doubt whether any petrol cars are quite exempt from occasional troubles of the kind. It is difficult to get anyone interested in the motor-car trade or any owner conceited about his own motor car to acknowledge the whole truth about this matter. And a person not acquainted with motors, judging merely by the comparative ease with which he usually sees two- and four-cylindered cars started in the street when the engine has not long [illegible] and is still warm can form no idea of what the unfor[illegible] before starting out from [illegible] strain seems to me really [illegible] mobilist to do as I have [illegible] hich will not suffer from [illegible] y a lady or a child I beg leave to make this communication.—I am, Sirs, yours faithfully,

London, Feb. 15th, 1904. C. B. KEETLEY.

A CAT STORY.

THE following is taken verbatim from the New York *Electrical Review* of Feb. 6th, the note within brackets being, of course, by the editor of that well known technical journal.

CAT ELECTRICITY CAUSES CATASTROPHE.

To the Editor of the Electrical Review.

There is an article in your paper describing a paper read at the meeting of the New York branch of the Society of Chemical Industry on "Electrostatic Influences on Inflammable Gases." I should like to state for the benefit of those who did not read the article I refer to that an explosion occurred recently at a home for lost cats through the static discharge from the back of a large tom. It is the system of this place to put the cats which are to be done away with into an iron box which is filled with gas. The explosion occurred when the attendants were putting the large tom into the case. He clung to the basket and in shaking him off generated enough static electricity to ignite the gas, causing the explosion.

Dover, N.J., Jan. 30th. R. RUSTLEWHITE.

[The explosion referred to above occurred at New York and the disastrous results are given in one of the daily papers as follows: [illegible] perhaps [illegible] Good- [illegible] ,' while companions held one of the [illegible] a tackle attached to the glass lid. The cats in these baskets were well behaved, but basket No. 4 contained a black cat. As soon as this animal was dropped there was a flash and a bang and a shower of cats and men."—ED.]

THE REFUGE ASSURANCE COMPANY, LIMITED, AND ITS MEDICAL ADVISERS.

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Jan. 30th, p. 345, a letter from the Law Union and Crown Insurance Company to its medical officers with your comments thereon. I should like to bring to your notice the inclosed slip from the Refuge Assurance Company. It was brought to me by one of their agents who said that if I would insure my life with them they would send me proposers for examination before acceptance by the company. I replied that this was a very one-sided agreement, but on promising to think the matter over he produced the inclosed. I then told him that it settled the matter as my fee was always a guinea, as no matter what the sum assured the amount of trouble and responsibility to me was the same. He replied that other medical men did the work for those fees and that one of them was in this town and he had never heard any objection made to them. After your remarks the other day it is superfluous of me to ask your opinion as to whether I did right, but I should like to know whether it is only the poorer companies who do this sort of thing to their medical officers. Alas, that such things should be or that such poor companies could exist.

I am, Sirs, yours faithfully,

Feb. 16th, 1904. "MONAS."

⁂ "The inclosed slip" sets out the following scale of fees: 5*s.* if the sum assured be £100 or under; 10*s.* for sums over £100 and under £200; and 20*s.* for any sum over £200. These figures speak for themselves.—ED. L.

THE BRITISH VIAVI CO.

To the Editors of THE LANCET.

SIRS,—A lady friend of mine recently replied to the following advertisement in the *Irish Times* (Dublin):—

> LADY, 30–35, well educated, capable of holding a responsible Business Position; good abilities, more important than any special experience; references and security. Apply, by letter, T 693, this office.

She received a reply asking her to call at the Dublin branch of the British Viavi Co., Limited, in Westland-row, Dublin (head offices, Regent House, Regent-street, W., formerly 52, Oxford-street, W.), and was interviewed by a lady who represented herself as the agent in Ireland, a manageress of the company. After a conversation extending over a couple of hours regarding the wonderful qualities of Viavi she learned that the company wanted a lady to open a branch for them in Belfast and that the lady would have to deposit with the company the sum of £300 *in cash* as security, for which she was to receive nothing save an acknowledgment.

My friend was offered in the alternative a position as canvasser for the Viavi productions on a commission of 25 per cent. To qualify for the latter she was asked to pay a fee of five guineas for instructions (to be returned as guaranteed commission), and to purchase certain charts at a further fee of five guineas.

I inclose you one of their pamphlets. Can you tell me, in confidence, or through your columns, anything about the company?

The request to deposit £300 and the fees for "instruction" and "charts" aroused the suspicion of my friend.

I am, Sirs, yours faithfully,

Dublin, Feb. 11th, 1904. CAVE.

⁂ If our correspondent will consult our issue of Feb. 13th, 1904, p. 482, he will see what we think about the Viavi treatment.—ED. L.

CLUB PRACTICE MEDICINE.

To the Editors of THE LANCET.

SIRS,—There is another phase of the question which "Inquirer" raises in your last issue—that of serum therapy. Who would like to treat a case of diphtheria, of even moderate severity, without using the antitoxin, and what can one call it but medicine? The expense of a minimum number of injections would be nearly twice the amount of the usual annual payment of each club patient.

I am, Sirs, yours faithfully,

Feb. 16th, 1904. CLUB SURGEON.

◆

Poor-law Appointment.—The examination referred to by our correspondent is one in medicine, surgery, and midwifery, so we think that one holding a certificate of having passed such an examination would be eligible for a Poor-law appointment, but as the Act governing such appointments is capable of different interpretations it might be as well for him to consult his legal adviser.

Mr. E. Hughes.—Our correspondent will find some information on the matter about which he inquires in the lecture by Dr. J. F. Woods, which appears in the present number of THE LANCET. He might also consult any general psychological treatises as well as various works on hypnotism.

Nemo should consult one of the recognised agents for the sale and transfer of practices or his solicitor. Every point that he raises is one for special arrangement.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 18th, 1904.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9 30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P M.).

TUESDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9 30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.).

WEDNESDAY (24th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9 30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

THURSDAY (25th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2 30 P.M.), Metropolitan (2.30 P.M.), London Throat (9 30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

FRIDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.).

SATURDAY (27th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.). Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (22nd).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Paper:—Mr. C. Robbins and Mr. J. T. Carter: Further Notes on some Prehistoric Skulls. Casual Communication:—Dr. H. B. Gardner: Variations in the Atmospheric Pressure and their Influence upon the Inhalation of Anæsthetics.

MEDICAL SOCIETY OF LONDON ([illegible] -square, [illegible] he W.).—8.30 P.M. Dr. T. B. Hy [illegible] Insane.—Dr. C. W. Buckley: [illegible]

TUESDAY (23rd).—THERAPEUTICAL SOCIETY (Apothecaries' Hall, Blackfriars).—3.30 P.M. Council Meeting. 4 P.M. Papers:—Dr. J. Burnet (Edinburgh): Ichthoform and Ichthorgan, an Account of their Therapeutic Applications.—Mr. W. McAdam *Eccles*: Some Remarks respecting Trusses and their Use.

THE LONDON LICENTIATES' AND MEMBERS' SOCIETY (Wimpole Hotel, 63, Wimpole street, W.)—4 P.M. Meeting.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8 30 P M Paper:—Dr. G. C. Garratt: Observations on Metabolism in the Febrile State in Man.

WEDNESDAY (24th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Clinical Evening. Exhibition of Cases.

THURSDAY (25th).—HARVEIAN SOCIETY OF LONDON (St. Mary's Hospital).—Clinical Meeting. Patients will be in attendance at 8.15 P M.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Lecture:—Mr. H. Hall: On Some Elementary Aims in Education.

FRIDAY (26th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.)—8 P.M. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 P.M. to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (22nd).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. A. Keith: The Structure and Evolution of the Auricles of the [illegible] round their great [illegible]

[illegible] [illegible]al, Hammersmith-[illegible] [illegible]gery.

[illegible] (22, Chenies-street, [illegible] (Skin.) 5.15 P.M.

UNIVERSITY OF LONDON.—5 P.M. Lecture:—Dr. A. E. Wright: Physiology of Immunisation.—On Anti-staphylococcus Inoculation.

TUESDAY (23rd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. M. Moullin: Posterior Dis-[illegible]

[illegible] [illegible]2, Chenies-street, [illegible] [illegible]dical.) 5.15 P.M.

[illegible] [illegible]ILEPTIC (Queen-[illegible] Subacute Combined Spinal Disease.

WEDNESDAY (24th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. A. Keith: The Structure and Evolution of the Auricles [illegible] Mechanism round their [illegible]

[illegible] [illegible]spital, Hammersmith-[illegible]

MEDICAL GRADU[illegible] W.C.).—4 P.M. [illegible] Mr. S. Stephens [illegible]

HOSPITAL FOR C[illegible] ton).—4 P.M. [illegible] its Uses.

LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—4 P.M. Lecture:—Diseases of the Stomach. (Post Graduate Course.)

THURSDAY (25th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 P.M. Dr. W. Williams: Deaths in Childbed, a Preventable Mortality.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—5 P.M. Mr. Keetley: [illegible]

MEDICAL GRADUATES' COLLEGE AN[illegible] W.C.).—4 P.M. Mr. Hutchinson: [illegible] Mr. E. Clarke: Errors of Refra[illegible] ment.

SAMARITAN FREE HOSPITAL FOR WOMEN (Marylebone-road, N.W.).—[illegible] [illegible]ration

[illegible] [illegible]F THE [illegible] The [illegible]urse.) [illegible]quare, [illegible]ure.) [illegible].C.).— [illegible] Hos-[illegible]

FRIDAY [illegible] ENGLAND.—5 P.M. [illegible] the Auricles of the [illegible] round their great [illegible]

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. R. J. Reece: Beri beri.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Clinique.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM			
One Year	£1	12	6
Six Months	0	16	3
Three Months ..	0	8	2

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Folkestone Express, East Ham and Barking Free Press, Daily News Advertiser* (*Vancouver*), *Darlington and Stockton Times, Daily News, Daily Chronicle, Hull and Lincolnshire Times, Westminster Gazette, Leeds and Yorkshire Mercury, South Bucks Free Press, Guernsey Star, Hertfordshire Mercury, Windsor and Eton Express, Standard, South Wales Daily News, Surrey Advertiser, Coventry Herald, Birmingham Daily Mail, Reading Mercury, Mining Journal, Local Government Chronicle, Liverpool Courier, Westminster Gazette, Pall Mall Gazette, Irish Times, Nottingham Guardian, Aberdeen Free Press* (*Weekly*), &c.

Communications, Letters, &c., have been received from—

A.—Dr. W. L. Ascherson, Lond.; Ambidextral Culture Society, Lond., Hon. Secretary of; Mr. W. H. Allen, Hurst Hill; Messrs. Allen and Hanburys, Lond.; Dr. J. J. Abraham, Lond.; Mr. F. Alcan, Paris; Dr. Arakel, Dardanelles; Admiralty Medical Department, Director General of.

B.—Dr. H. Charlton Bastian, Lond.; Dr. F. H. Burton-Brown, Rome; Messrs. Burroughs, Wellcome, and Co., Lond.; Bradford Children's Hospital, Secretary of; Bradford Eye and Ear Hospital, Secretary of; British Medical Benevolent Fund, Hon. Secretary of; Dr. A. Baxter, Darwen; Dr. O. F. Ball, St. Louis U.S.A.; Messrs Brady and Martin, Newcastle on-Tyne; Messrs. Bates, Hendy, and Co., Reading; Dr. W. Bryce, Edinburgh; Beta, Lond.; Mr. C. L. Bedford, Lond.

C.—Messrs. J. A. Carveth and Co., Toronto; Mr. Mayo Collier, Lond.; Messrs. F. Comar and Son, Lond.; Mr. Ralph B. Canning, Lond.; Messrs. Cole and Co., Lond.

D.—Mr. T. C. Down, Lond.; Messrs. G. L. Daube and Co., Frankfurt; Professor George Dock, Michigan; Dr. F. Dittmar, Scarborough; Mr. F. Dudley, Bodmin; Mr. T. Dixon, Lond; Denbigh Infirmary, Secretary of.

E.—Captain H. M Earle, I.M.S., Dharmsala, Punjab; E. W. P B.; Mr. J. Jameson Evans, Birmingham.

F.—Messrs. Ferris and Co., Bristol.

G.—Sir W. T. Gairdner, Edinburgh; *Graphic (The)*, Lond., Editor of; Germicide Remedy Co., Chicago, Secretary of; Dr. J. Gilroy, Waterbeck; Messrs. Gale and Co., Lond.; G. F. G.; Messrs. Grace Bros. and Co., Lond.; G. T. B.; Mr. A. J. Gilbert, Swindon; Guest Hospital, Dudley, Secretary of; Messrs. A. Goldschmidt and Co., Lond.

H.—Mr. J. Hutchinson, jun., Lond.; Mr. R. Hughes, Bala; Dr. R. Hutchison, Lond.; Messrs. Haar and Steinert, Paris.

K.—Dr. W. E. dé Korté, Lond.; Dr. R. Lawford Knaggs, Leeds; Mr. R. C. B. Kerin, Lond.; Messrs. R. A. Knight and Co., Lond.; Dr. Skene Keith, Lond.

L.—Mr. S. R. Littlewood, Lond.; Professor J. N. Langley, Cambridge; Dr. J. C. G. Ledingham, Aberdeen; Mr. R. Lee, Lond.; Messrs. Longmans, Green and Co.; Lond.; Messrs. Lea Bros. and Co., Philadelphia; Mr. H. K. Lewis, Lond.; Messrs. C. and E. Layton, Lond.; Leeds Hospital for Women and Children, Secretary of; London Hospital, Secretary of.

M.—Dr. Robert J. Mackeown, R.N., H.M.S. *Alacrity*, China Station; Dr. H. Macnaughton-Jones, Lond.; Mr. P. McDermott, Lond.; Dr. W. H. Maidlow, Ilminster; Dr. C. F. Marshall, Edgbaston; Messrs. C. Mitchell, and Co., Lond.; Monas; Mining Engineers, The Institution of, Secretary of; Dr. J. C. Muir, Lond.; Maltine Manufacturing Co., Lond.; Messrs. J. Maythorn and Son, Biggleswade; Messrs. Macmillan and Co., Lond.; Manchester Medical Agency; *Midland Counties Herald*, Birmingham.

N.—Mr. J. Niven, Liverpool; Dr. David Newman, Glasgow, Nurses' Co-operation, Lond., Secretary of; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Dr. John T. Nelson, Hamilton.

P.—Mr. William Pooley, Rochdale; Mr. Y. J. Pentland, Edinburgh; Mrs. Powell Lond.; Messrs. Peacock and Hadley, Lond.

R.—Mr. P. Rose, Lond.; Mr. L. H. Ruegg, sen., Sherborne; Dr. Alonzo G. Rider, Devonport; Dr. Percy Rendall, Ewell; Messrs. F. A. Richter and Co., Rudolstadt; Royal Society of London, Secretary of; Royal Meteorological Society, Assistant Secretary of.

S.—Dr. Herbert Snow, Lond.; Professor John Lindsay Steven, Glasgow; Mr. J. H. Spreat, Bath; Salutaris Co., Lond.; Sanitary Wool Wood Co., Lond.; Messrs. Speyer and Peters, Berlin; Mr. Gerald Sichel, Lond.; Dr. P. W. G. Sargent, Lond.; Messrs. Spiers and Pond, Lond.; St. Bartholomew's Hospital, Rochester, Secretary of; S. T.; S. H. M.; Dr. S.; Messrs. A. Scialom and Co., Salonica; Scholastic, Clerical, &c., Association, Lond.; Messrs. W. B. Saunders and Co., Lond.; "Sister," New Cavendish-street.

T.—Dr. Hugh Thursfield, Lond.; Dr. John W. Taylor, Birmingham; Dr. Frederick Taylor, Lond.; Turkey, Ambassador of, Lond.

W.—Messrs. F. Williams and Co., Lond.; Dr. F. Parkes Weber, Lond.; Dr. F. R. Walters, Farnham; Mr. S. Wand, Leicester; Dr. J. Smith Whitaker, Lond.; West End Hospital, Lond., Secretary of; Dr. W. Williams, Cardiff; Mr. H. M. Woodcock, Bromley; Mr. C. E. Woakes, Lond.; West Riding County Council, Clerk of; Messrs. J. Wright and Co., Bristol; West Bromwich District Hospital, Secretary of.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. H. R. Andreae, Lond.; Dr. G. N. Adams, Sunderland; Apollinaris Co., Lond.

B.—Dr. R. L. Bowles, Lond.; Dr. W. E. Barton, Lond.; Messrs. J. Beal and Son, Brighton; Berrow's Worcester Journal Co., Secretary of; Dr. J. Burnet, Edinburgh; Birmingham Skin Hospital, Secretary of; Mr. J. Boot, Nottingham; Mr. W. P. Bothamley, Lond.; Mr. A. A. Bradburne, Ryde; British Lysoform Syndicate, Lond., Secretary of; Mr. G. W. Brown, Hanley.

C.—Mr. Harrison Cripps, Lond.; Messrs. T. Cook and Son, Lond.; Mrs. Campbell, Lond.; Coventry and Warwickshire Hospital, Secretary of; Cambridge Typewriting Agency, Lond.

D.—Mr. W. T. Davies, Llananno; D. D.; Dr. J. Dee, Walton-on-Naze; Mr. R. Davis, Lond.; Mr. A. Dyett, Sevenoaks.

E.—Messrs. Evans, Sons, Lescher, and Webb, Lond.; Dr. E. Elsmere, Chandler's Ford; E. G.

F.—Dr. A. M. Fraser, Lond.; Dr. W. Balfour Fergusson, Painswick; F. T. H.; Mr. J. Flach, Lond.; Dr. H. C. Ferguson, Glasgow.

G.—Mr. W. Greene, Monkstown; G. M.; Mr C. W. Ginn, Lond.; Messrs. R. Grieve and Son, Dumfries; Glasgow Corporation, Treasurer of; Mr. H. Bellamy Gardner, Lond.

H.—Dr. C. Holman, Lond.; H. B.; Messrs. J. Haddon and Co., Lond.; Messrs. Hastings Bros., Lond.; Heigham Hall, Norwich; Dr. J. M. Henry, Glasgow.

I.—Dr. J. B. Isaac, Passage West; Miss E. R. Inge, Haslemere.

J.—Dr. J. Johnston, Bolton; Messrs. W. and A. K. Johnston, Edinburgh; J. R. J. R.; Mr. J. Jackson, Stockton Heath; Dr. J. E Jones, New Quay.

K.—Dr. W. Kingdon, Lond.; Dr. H. G. Kyle, Bristol; Dr. H. Kenwood, Lond.; Dr. J. E. Kelly, New York; Dr. J. Kerr, Shirebrook.

L.—Dr. H. Lloyd, St. Asaph; Dr. F. W. Lamb, Dorchester.

M.—Dr. Wm. Milligan, Manchester; Manchester Hospital for Consumption, Secretary of; Mr. J. D. Murdoch, Liverpool; Dr. F. Morris, Cape Town; Mount Vernon Hospital, Lond., Secretary of; Matron, Hove; Manchester Northern Hospital, Secretary of; Mr. E. Muller, Lond.; Mr. J. J. MacGrath, Dunfanaghy.

N.—Dr. M. G. Naidu, Hyderabad; Mr. D. M. Nairn, Blenheim, New Zealand; Mr. S. C. M. Nourse, Clacton-on-Sea; Dr. A. Nasmyth, Penicuik; National Hospital for the Paralysed, Lond., Secretary of.

O.—Dr. J. O'Neill, Athy; Oldham Infirmary, Secretary of; Mr. J. M. O'Sullivan, Cardiff.

P.—Mr. J. W. Parry, Upper Solva.

Q.—Queen's College, Cork, Bursar of.

R.—Lieutenant Colonel R. B. Roe, I.M.S., Amraoti, India; R., Ackworth; Messrs. Rutley, Son, and Vine, Lond.; Mr. J. Red, Edgware; Mr. P. H. Ross, Entebbe, Uganda; Royal Hants County Hospital, Winchester, Secretary of; Mrs. Rayner, Exmouth.

S.—Sheffield Corporation, Treasurer of; South Devon and East Cornwall Hospital, Plymouth, Secretary of; Messrs. Scott and Bowne, Lond.; Dr. J. A. Shaw Mackenzie, Lond.; Mr. J. Snell Gargrave; Messrs. J. Smith and Son, Glasgow; Dr. R. N. Salsman, Lond.

T.—Dr. J. Thomson, Gartcosh.

V.—Vinolia Co., Lond.; V. W., Old Windsor.

W.—Dr. A. D. Waller, Lond.; W G.; W G. H; W. S. C. D; W. C. C.; W. E. S., Rev. A W. Watson, Churt; Messrs. Wm. Wood and Co., New York; Mr. A. F. Wilson, Copford; Worcester General Infirmary, Secretary of; Mr. H. J. Walker, Lond.; Mr. A. O. Way, Bassett; Dr. J. D. Windle, Southall.

Y.—Yorkshire College, Leeds, Secretary of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

ABSTRACT OF

The Hunterian Lectures

ON

THE EVOLUTION AND ACTION OF CERTAIN MUSCULAR STRUCTURES OF THE HEART.

Delivered before the Royal College of Surgeons of England on Feb 22nd, 24th, and 26th, 1904,

By ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR ROYAL COLLEGE OF SURGEONS OF ENGLAND, LECTURER ON ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.

LECTURE I.

Delivered on Feb 22nd.

MR. PRESIDENT AND GENTLEMEN,—It is with a feeling of keen disappointment that men who seek to extend our knowledge of the origin and development of the human heart lay down any of the standard treatises on the function and diseases of that organ. Their labour, apparently, as far as one may judge from the perusal of such works, lies outside the field of practical medicine and is useless to physician and physiologist alike. The purpose of these lectures is to show that, by studying the unique collection of vertebrate hearts in the museum of this College in the manner which Hunter intended them to be studied and by using them to interpret the developmental phases of the human heart, light can be thrown on certain obscure problems concerning the action of the heart in health and disease.

PULSATION IN THE VEINS.

In the later stages of heart disease, when the right side becomes engorged, well-marked pulsations may appear in the veins of the neck. Thanks to the careful observations of Dr. James Mackenzie,[1] we know that these pulsations or rises of pressure in the great veins occur at two points in the cardiac cycle: (1) during auricular systole and (2) towards the end of the ventricular systole. In early cases of back pressure both these pulsations are present; in the latest stages the ventricular wave gradually merges with, and ultimately absorbs, the auricular wave. If Mackenzie is right in regarding these venous pulsations as directly due to the contraction of the auricular and ventricular chambers, then it is plain that the caval orifices of the auricle have been rendered incompetent when these waves appear. Whenever the great veins pass behind the clavicle above or Poupart's ligament below and come to lie within the respiratory area of negative pressure they lose their valves and there is thus no obstacle to prevent the appearance of a regurgitant wave from the auricle in either the jugular bulb above or termination of the femoral vein below. The problem as to the cause of these two venous waves, named by Mackenzie the "auricular" and "ventricular," is rendered more difficult by the fact that both of them, although much less marked in amplitude, occur in veins in health[2] During auricular systole the auricular mouths of the venæ cavæ are closed; the venous blood is dammed back, giving rise to the normal auricular venous wave. In health there is no regurgitation during systole from the auricles,[3] but in disease there is apparently added to the normal back pressure in the veins an increase due to a regurgitation during auricular systole.

The point to be settled first is: How are the caval orifices closed during auricular systole? The current teaching is that they are closed by the contraction of muscular fibres which surround the terminations of the great veins. The largest vein of all, the inferior vena cava, has no annular muscular fibres surrounding its termination; those round the superior vena cava are weak and do not seem strong enough to act as a competent sphincter. The coronary sinus, on the other hand, is covered by circular and longitudinal layers of muscle and is provided with competent valves as well. Thus the explanation usually given of the manner in which the venous orifices are closed breaks down under anatomical examination and the true explanation is still to seek.

THE MANNER IN WHICH AURICULAR REGURGITATION IS PREVENTED IN LOWER VERTEBRATES.

When one sees the secure manner in which the venous valves prevent blood returning to the veins during auricular systole in the three lower classes of vertebrates, it becomes a matter of the highest probability that there is a corresponding functional mechanism in the two highest classes—birds and mammals. In fishes amphibians, and reptiles all the veins of the body unite at their terminations in a common dilatation or reservoir—the sinus venosus. The margins of the fissure-like mouth by which the venous blood passes from the sinus to the auricle are guarded by two strong membranous valves, which are right and left in position, and unite at their upper and lower ends in drawn out angles or fornices. During the auricular systole the valves are rendered taut and competent. The venous sinus and the venous valves appear in the human embryo as they do in that of every vertebrate, and are at first well-developed structures functionally active. During the third, fourth, and fifth months of embryonic life the valves and the auricular muscle which acts on them undergo a gradual transformation, until by a reduction of one part and an increased development of another there is evolved a mechanism which takes on the function of the valves. No organ in the whole body is so conservative in its tendencies as the heart; what improvement it has obtained in the course of its history it never loses; its progress is made not by the introduction of new structures but by modification of the old.

The structures in the right auricle which arise from the venous valves and the musculature of the valves and which we may expect to be concerned in the closure of the caval orifices are represented in Fig 2. For comparison there are represented in Fig. 1 the venous valves in the right auricle of a child who lived for some weeks after birth; in their form and attachments they resemble exactly the venous valves of a reptile. The lower part of the right venous valve

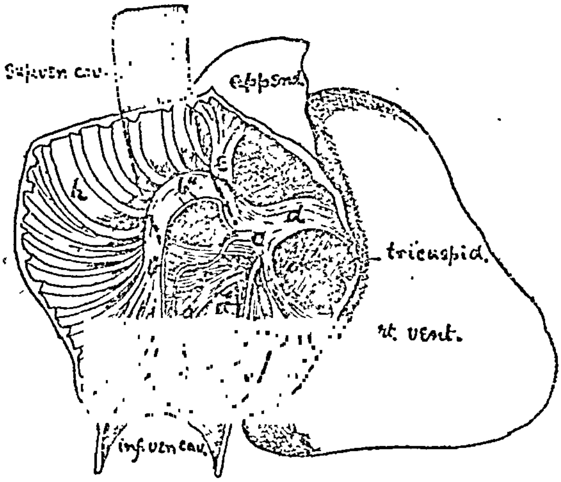
forms the Thebesian and Eustachian valves (Fig. 2) which still help to guard the opening of the coronary sinus and inferior vena cava. The upper part of the right valve disappears but it is not an uncommon thing to see a trace of it on the septal wall between the caval orifices and ending above by passing across the anterior margin of the superior caval orifice to end on the septum in front of that orifice (Fig. 2). The disappearance of the valve is due to an enormous development of the musculature of its base; it forms a great rounded fasciculus, the right tænia terminalis,[4] which commences in the inter auricular septum and passing across the anterior margin of the superior caval orifice turns down in the wall of the auricle to terminate by feeble fasciculi in the Eustachian valve and outer margin of the inferior caval orifice (Fig. 2). Below, where the right venous valve has preserved the primitive form, its musculature is nearly absent. From the right tænia terminalis rise the musculi pectinati. In auricular systole the tænia terminalis sinks like a guillotine blade within the auricle over the mouths of the venæ cavæ, thus assisting to close the orifices.

FIG. 2.



Right auricle of a child thrown open to show the position of remnants of the venous valves and of the muscular bands developed from their bases. *a. a*, Position of the left venous valve. *a'*, Remnant constantly present at the lower margin of the septum ovale. *b*, Thebesian valve. *b'*, *b'*, Eustachian valve *b''*, *b'*, On the right tænia terminalis, and showing other remnants of the right venous valve. *c*, Between the upper and lower fornices of the venous valves. *d*, Annular fibres of the auricular canal. *e*, Tensor of appendix. *f*, Upper band of auricular muscle which breaks across opening of sinus venosus. *g*, The lower band. *h*, Musculi pectinati. *k*, Sub-Eustachian sinus.

The only trace that remains of the left venous valve is a membranous reticulation seen on the inner or septal margin of the inferior caval orifice along the base of the fossa ovalis (Fig. 2). In fœtal and abnormal hearts the valve can be traced upwards till it unites with the right valve below the superior caval orifice and downwards on the septum till it joins the Thebesian part of the right valve (Fig. 2). Thus the upper and lower fornices of the venous valves come to lie on the septum of the adult auricle. The musculature of the left valve remains as a narrow flat bundle that is best seen beneath the remnant of the valve below the fossa ovalis. It can be traced above to the upper fornix and below to the lower (Fig. 2).

While the musculature of the right venous valve has undergone a new development both valve and musculature of the left side have atrophied. The atrophy is due to the appearance of two new bands of muscle, derived from the septal wall of the auricle. It is the development of these two bands that relieves the left valve of its function and causes its atrophy. They arise in this way. The wall of the sinus venosus becomes thrown into two folds; one of these projects within the right auricle (Figs. 1 and 2) between the orifices of the superior and inferior venæ cavæ; the other between the orifices of the inferior vena cava and coronary sinus. In these two inflections of the sinus wall muscular bands from the septum pass beneath the base of the left valve and gain an attachment to the right. In this manner the sinus venosus is absorbed in the right auricle and the original opening between the venous valves is divided into three parts—the upper for the superior cava, the lower for the coronary sinus, and the intermediate for the inferior vena cava. By the action of these structures derived from the venous valves and the two auricular bundles that have broken across the venous sinus the orifices of the veins are closed during the systole of the auricle. It is important to remember that the muscle of all these structures is derived from the musculature of the auricular canal (for the interauricular septum is derived from the canal), which we know, from the researches of Gaskell[5] on the heart of the tortoise, and MacWilliam[6] on that of the eel, is more easily stimulated to contraction than that of the proper auricle. The proper auricle is developed as a diverticulum of the canal.

THE MANNER IN WHICH THE VENOUS ORIFICES ARE CLOSED.

The movements of the living auricle are so quick that it is impossible to follow them with the eye. By using a modification of the method adopted by Hesse[7]—namely, by throwing injections of molten paraffin wax at the temperature of boiling water into the auricles of the dead heart their walls can be thrown into a condition of heat contraction, which, as far as the change of form is concerned, resembles approximately the natural contraction. The injection must be made while the heart is still within the unopened thorax and after the blood has been washed out from the auricles. When such an injection is made it will be found that the wax within the auricles is partially or sometimes completely separated from that within the great veins by the contraction of the structures which have been described as arising from the venous valves. There is the further advantage in this method of investigation that the action of the various parts of the auricular wall may be studied, for on the cast within the auricle are impressed the various muscular bands, and one can see at a glance what part each will play in propelling the load of the auricle.

The structures which close the orifice of the superior vena cava are shown in Figs. 2 and 3. Along the anterior margin of the orifice, which is oval in shape, passes the right tænia terminalis; along its posterior or septal margin runs part of the muscular band which broke across the sinus venosus between the superior and inferior venæ cavæ. Between

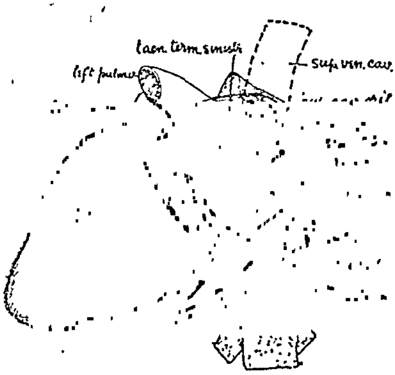
these strong muscular bands the orifice of the superior vena cava is reduced to a fissure in auricular systole. The muscular fibres which surround the terminal part of the superior vena cava also help to secure the orifice (Fig. 3). These fibres are derived from the musculature of the sinus venosus, the most excitable of the auricular musculature. In front of the termination of the superior vena cava but separated from it by the tænia rises up a thin-walled diverticulum of the auricle which acts towards the tænia the part which a sinus of Valsalva serves to a semilunar valve.

At the inner or septal angle of the superior vena cava (see Fig. 4) the septal fibres behind the orifice of that vessel and those of the right tænia terminalis become continuous with a band which crosses the roof of the left auricle. As it is a constant feature of the hearts of birds and mammals, and is similar in origin and function to the tænia of the right side, it may be named the left tænia terminalis. The two tæniæ form together a horseshoe shaped band which encircles and helps to close the venous orifices of both auricles (Fig. 4). They terminate below on and near the right and left margins of the inferior vena cava. The terminal part of this vessel, which is fixed in the diaphragm and pericardium, forms the fulcrum on which and from which the tæniæ act in auricular systole.

FIG. 4.



View of the human heart from behind, showing diagrammatically the relationships of the tænia terminalis of the right and left auricles.

The inferior caval orifice, which is double the size of the superior, is closed by the anterior margin, which carries the Eustachian valve, being drawn inwards until it comes in contact with the inner or septal margin. On the septal margin is situated the septum ovale, and since the pressure in the left auricle is held to be the greater in systole it is possible that the septum may bulge to meet the incoming lateral margin. That margin is drawn inwards by the muscular bands which broke across the common orifice of the sinus venosus. These bands surround the fossa ovalis and form what is called at present the annulus ovalis or limbus of Vieussens, but when that structure is examined it will be seen to be composed of an upper and lower part which are only partly fused together at their origin in the interauricular septum (Fig. 2). The lower band, or inferior limbic band, which broke across the venous orifice between the inferior caval and coronary orifices, ends in the Eustachian valve and in the margin of the inferior vena cava. The upper limbic band, which forms only part of the auricular fibres which crossed the sinus venosus between the caval orifices, also ends in the lateral margin of the inferior vena cava. By the contraction of these bands, aided also by the terminal fibres of the right tænia terminalis, the lateral and septal margins of the inferior caval orifice are brought in apposition, so that the Eustachian valve is brought against the septum ovale and renders the orifice competent. But while the closure of the superior caval orifice is wholly due to the muscular bands which surround it that of the inferior is accomplished partly by mechanical means. The free edge of the Eustachian valve may be reticulated or absent but its basal part is constantly present. The auricular wall at the base of the Eustachian valve forms a thin-walled projecting sinus in the hearts of all mammals (Fig. 3, *c*) which by its distension during auricular systole helps to press inwards the Eustachian valve and lateral margin of the inferior caval orifice against the septal margin. In the later stages of cases of auricular hypertrophy the wall of the sinus becomes thickened and its extent less defined; in distension of the auricle, with atrophy of its wall, the sinus becomes greatly distended and may reach a large size. The orifice of the coronary sinus is closed by the Thebesian valve and the annular fibres of the auricular canal, amongst which the orifice is imbedded. In auricular systole the base of the right ventricle is drawn towards the opening of the inferior cava, this movement greatly aiding the closure of the orifice by the structures described.

THE REASON FOR THE DISAPPEARANCE OF THE VALVES.

The venous valves are reduced and the muscular bundles described above appear in those animals in which the heart is completely separated into right and left halves. Complete division is only found in the hearts of birds and mammals. A rigid, mechanically accurate mechanism is replaced by one which will allow regurgitation during engorgement of the auricle. If the auricles of an amphibian or reptile become overfilled by active exercise, the right heart quickly relieves itself into the left side through the interventricular foramen, but when that communication is closed then of necessity a safety mechanism must be introduced at the venous orifices of the right auricle so that the auricle may not overload the ventricle *The function of the auricle* appears to be not only to fill the ventricle but to regulate the load of the ventricle.

THE AURICULAR VALVULAR MECHANISM IN CASES OF VENOUS PULSATION.

Dr. Mackenzie was good enough to submit to me for examination four hearts from cases in which he had taken records of the pulse in the veins for some years before death. Besides these I had at my command a series of specimens showing greatly distended auricles in the museum of the London Hospital Medical College, but of these I had no history as to the venous pulse. Dr. Mackenzie's cases [illegible] mitral and tricuspid stenosis; in all the auricles were [illegible] *hypertrophy of the* [illegible] r there was extreme atrophy, and the remaining two specimens showed intermediate conditions. In all, too, the appendix of the auricle was filled by an ante-mortem clot. The tænia terminalis was in all greatly elongated, but it was hypertrophied in the hypertrophied auricle and small in the one which showed marked atrophy. The parts which were markedly changed were the bands which I have described as crossing the original mouth of the venous sinus; the septal fibres which help to close the superior caval orifice and the limbic bands which close the inferior caval orifice were stretched to nearly twice their normal length. The Eustachian valve and its sinus were also distorted or absent. The muscular fibres round the terminal part of the superior vena cava were partially atrophied in all these hearts. The caval orifices, especially that of the superior vena cava, were also dilated.

A marked feature of all these cases in which the auricles are greatly distended is the great extension of the interauricular septum. Normally in the diastolic condition it measures about an inch when the distance is reckoned from a point taken between the caval orifices to one on the margin of the septum which lies against the aorta, but in mitral disease this diameter frequently measures two and a half or three inches. With this extension of the septum the foramen ovale may become widely open. That need not mean that the foramen ovale has been opened afresh, for in the valuable statistics given by Professor E. Fawcett and Dr. J. V. Blachford[8] this foramen was found patent in 27 per cent. of subjects which were over 20 years of age.

RELATIVE COMPETENCY OF THE VARIOUS ORIFICES.

From an examination of the anatomy of the parts one would say without hesitation that the superior caval orifice is by far the most strongly guarded and least likely to allow regurgitation in auricular systole. The inferior caval orifice, unprotected by circular fibres, and partly mechanical in its manner of closure, seems, on the other hand, one that would be easily deranged and rendered incompetent by distension of the auricle. The coronary orifice stands, in the strength of its guard, intermediate to the other two. The clinical experience of Dr. Mackenzie points in an exactly opposite direction. It is to be observed in the first place that he uses the pulsation of the liver as an index of the extent to which regurgitation takes place through the inferior caval orifice in auricular systole; an auricular pulsation he found to occur in the liver only when there was tricuspid stenosis with hypertrophy of the right auricle, whereas an auricular systolic wave occurred in the jugular vein in all heart cases where there was over-distension of the right side. That observation leads one to conclude that a venous pulsation in the liver is produced under a considerable positive force, such as can be produced by a hypertrophied auricle, the force of which is diverted by the narrowed tricuspid orifice or by the ventricle acting through an incompetent tricuspid orifice. An exaggeration of the normal auricular wave, seen in the jugular veins in cases of back pressure, need not mean an actual regurgitation from the auricles, for in these cases the great veins are so distended that the mere occlusion of their orifices during auricular systole would be sufficient to produce the auricular wave seen in the earlier stages of venous back pressure. On anatomical grounds one would expect a positive auricular wave, due to regurgitation of the auricular blood, to appear in the tributaries of the inferior before it can be felt in those of the superior vena cava.

THE EFFECTS OF ADHERENT PERICARDITIS.

Clinicians readily admit that there is still much that is obscure in the sequelæ of pericarditis. When adhesions form after pericarditis they begin between the auricles and the pericardium where the great veins pierce to enter the heart and where the structures which close the venous orifices are situated. Mere adhesion of the auricles to the pericardium, while it may lead to some hypertrophy of the muscular wall, will not markedly affect the normal action of the auricles so long as the outer surface of the pericardium remains free. But when the pericardium becomes adherent to surrounding structures the muscular bands which surround the venous orifices are greatly handicapped by the adhesions and regurgitation takes place. Dr. J. H. Sequeira[9] found that liver tenderness was one of the most common sequelæ of adhesive pericarditis; the tenderness may be due purely to the venous back pressure, but that back pressure will be increased if the auricle adds part of its load to the already distended veins of the abdomen. In cases of adhesive pericarditis with great distension and hypertrophy of the auricles, the caval opening in the diaphragm will be found greatly reduced in size, not from a cicatricial contraction but evidently owing to an attempt to ameliorate the conditions resulting from an incompetency of the auricular orifice of the inferior vena cava.

FIXATION OF THE HEART IN CASES OF PERICARDITIS

When the pericardium becomes fixed by adhesions to the lungs and chest wall a number of obscure symptoms follow owing to the arrest of the normal respiratory movements of the heart. The type of respiration may change; the patient, instead of gaining his inspiratory space by a forward heave of his abdominal wall, due to the descent of the diaphragm, inspires by expanding the walls of his chest and body in a lateral direction. Further, in some of these cases, especially if the inflammatory process and adhesions have been confined to the structures of the posterior mediastinum between the base of the heart and the spinal column a peculiar type of heart action—pulsus paradoxus—may appear in which the pulse beat is stronger or only perceptible during expiration. These conditions find their explanation in the disturbed respiratory movements of the heart.[10] John Hunter[11] laid it down as a morphological law that the heart is attached to the organs of respiration and follows the movements of these organs When the lungs supplant the gills the heart migrates from the neck to the thorax In mammals the heart is firmly fixed to the roots of the lungs by fibrous prolongations of the pericardium carried into them on the pulmonary veins and mesentery which fixes the base of the heart to the dorsal wall of the body cavity that the developed and from which they sprout out as buds. dorsal mesentery forms that part of the binds the pulmonary roots and the base of the heart A true conception of the respiratory movements of the heart has been retarded by the traditional statement that the roots of the lungs are fixed parts. It is impossible that could be a movement of the base of the heart corresponding movement of the roots of the lungs, so closely are they bound. It is admitted on all hands since the introduction of the x rays that there is a very movement of the base of the heart during inspiration downward and forward direction. In that merely follows the roots of the lungs. The lung expand either in a backward, inward, or upward because in these directions the chest wall cannot be enlarged. It will be found that the apex of the lung is fixed point from which the inspiratory movement of lung takes place and from it the expansion of the lung proceeds in a forward, downward, and outward direction. In this general movement of the lung the root The extent of the movement of the root is indicated in life by the shadow of the base of the heart. The lungs in all their movements carry their pump with them. In no is the inspiratory movement of the pulmonary roots so great as in man, because in him the heart and the roots of the lungs are so firmly bound to the diaphragm (see Fig. 5).

FIG. 5.

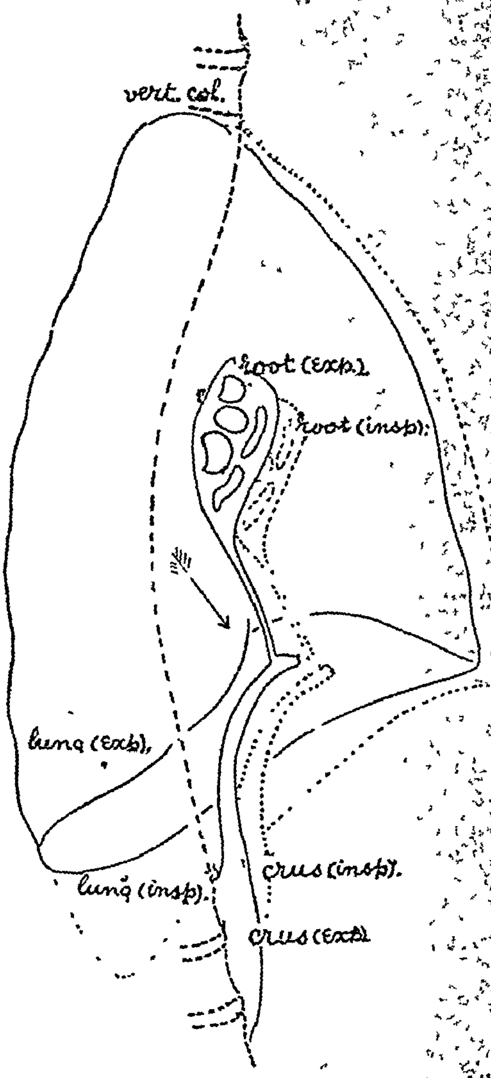

Diagram to show the directions in which expansion of the lung takes place during inspiration and the corresponding movement of the root. (From THE LANCET, March 7th, 1903, p. 634.

Mere adhesion of the heart to the pericardium does not interfere with the cardiac respiratory movements but when adhesions fix the pericardium to the lungs at each side and to the chest wall in front and behind these movements become impossible and cease to take place. The patient then develops a type of respiration which can be performed without moving the roots of the lungs. That is accomplished by expanding his thoracic wall in a lateral direction. In that movement the central part of the diaphragm and its crura take no part. If, however, only the base of the heart is attached to the posterior thoracic wall by the adhesions which follow posterior mediastinitis, the lungs being left unaffected and free, then, when a breath is taken, a strain is thrown on the structures in the roots because the heart cannot follow the movement of the lung. It seems to me that such a strain would be sufficient to retard or to stop the flow of blood in the pulmonary veins during inspiration but as yet no opportunity has occurred to me of verifying this theory.

ABSTRACT OF

The Hunterian Lectures

ON

THE AFTER-EFFECTS OF HEAD INJURIES.

Delivered at the Royal College of Surgeons of England on Feb. 15th, 17th, and 19th, 1904,

By T. CRISP ENGLISH, F.R.C.S. Eng.,
HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

LECTURE II.[1]

Delivered on Feb. 17th.

Mr. President and Gentlemen,—At the conclusion of my last lecture I was dealing with the mental disturbances which follow injuries to the head. I shall next speak of the impairment of certain special intellectual faculties.

Motor aphasia is a well-known consequence of injuries to Broca's speech centre. A typical example was seen in a man, aged 52 years, nine months after a blow with a pitchfork exactly over Broca's area. The aphasia had improved somewhat since the accident and was associated with severe localised headache and giddiness. Operation was recommended but refused. Aphasia was present in three other patients, being associated with hemiplegia in two; all these cases are included in the third series. I have met with no example of the interesting condition known as "*recurring utterances*" continuing for a long period after the head injury, although I have several times seen it during the gradual return to consciousness after cerebral contusions and lacerations. The expression "recurring utterances" is applied to verbal repetitions made by the patient at every attempt to speak. One word or one phrase may be constantly repeated perhaps for months, years, or even a lifetime after an injury which has involved the centres of speech. Sometimes it is the last word spoken before the accident, sometimes it is part of a word, sometimes a meaningless expression. In one reported case the last words used by the patient before loss of consciousness had been "Mrs. Walker" and later the "recurring utterances" occurred in the constant repetition of the word "Mrs."

Traumatic amnesia of some kind is very common, varies greatly in degree, and may be temporary or permanent. It is important to distinguish between loss of memory of the details of the accident, loss of memory of events preceding the accident, and the later impairment of memory. The loss of memory of the details of the accident and the events immediately following it is well known. This was found in many of the patients and was as a rule permanent. Sometimes the loss may be gradually repaired, as in a case recorded by Kompken, in which a man after a head injury had entirely forgotten the events of the three days following it and each day was successively remembered until at last the accident itself was recalled. In a certain number of cases after recovery from the early symptoms the patient finds to his surprise that he has forgotten entirely not only the accident and the succeeding circumstances but a certain length of time, varying from a few hours to a few days or even longer, before the accident occurred. A few cases are recorded in which the whole of the patient's previous life became a complete blank to him. Abel[2] reported a case of puncture of the frontal part of the brain in which the patient's life for 20 years before the accident was completely obliterated from his memory. He failed to recognise his wife and old friends and asserted that he had never worked on the railway but was a farm labourer. He had, however, been a railway labourer for 20 years and before that time had worked on a farm. A year later there was some partial return of memory.

Distinct from these cases we have the later amnesia, varying from slight difficulty in remembering names and numbers to extreme impairment of memory. This condition was found in 36 cases in series 1 and in 21 in series 2, but probably occurred in many others. Generally speaking, where symptoms following head injuries were marked there was some impairment of memory. There are two distinct varieties of this condition. In the majority of cases it is an outcome of the general nervous instability: the patient is unable to fix his attention and to concentrate his thoughts and the result is impairment of memory. In some cases there has been a definite lesion of one or more of the centres for special memories, such lesion being usually cortical contusion or laceration.

Agraphia is sometimes a consequence of cerebral injuries which persists for several months or even indefinitely. It [illegible]

[illegible] words of more than two syllables. Sometimes the patient realises his mistakes; in other cases he is quite satisfied with what he has written until his attention is drawn to the wrong words and even then may be unable to grasp the nature of the mistake.

Loss or impairment of the arithmetical faculty is a curious and not uncommon feature; I have met with several instances. The business man may be quite unable to add up the simplest column of figures, the attempt to do so being a complete failure and producing headache. I tried this test with several patients and the frequency with which the simplest arithmetic baffled them was very interesting. This faculty is one most commonly impaired after head injuries and often the last to be recovered completely. For business men, then, I should recommend a much longer period of mental rest than for men engaged in other pursuits, for such a man takes much longer before he is fit to return to his business than the man whose occupation is purely manual.

The *musical faculty* is sometimes lost when all others are retained. I tested this faculty in several cases but found no instance in which it was impaired. There are a few remarkable instances on record in which patients have had periods in which they cannot speak words but can only sing them.

[illegible] *somnambulism* sometimes occurs, especially in [illegible] ain acts quite uncon- [illegible] of what he has done. I met with an example of this condition last year. The patient, a man, aged 26 years, was at a convalescent home five weeks after concussion; he was found walking about unconsciously at night and when taken back to bed had no memory of his action beyond stating that he could not find his way about at night. He was quite well during the day. It was thought that this was due to his having played cricket in the sun, but the sun was not strong then, and I am inclined to think that the excitement of cricket was the more important factor. There had been no somnambulism before the accident.

Lesions of the cranial nerves will be mentioned next. *Loss of smell* was found in four cases at periods of one and a half, six, six and a half, and ten years respectively after the accident; in three cases the base of the skull had been fractured. One patient who had sustained a severe fracture of the anterior fossa stated that the loss of smell was not noticed until one and a half years after the accident. He said, as is often said by such patients, that he had also lost the sense of taste. He described it thus: "I can distinguish decided tastes, such as sugar or salt, but not the finer ones, such as mutton, beef, or game of any sort." Subjective sensations of this special sense are usually the result of hæmorrhage in the anterior fossa or direct damage to the olfactory bulb and its branches, in the common accidents in which the frontal lobes are injured by *contrecoup*.

---

[1] Lecture I. was published in The Lancet of Feb. 20th, 1904, p. 485.

[2] Brit. Med. Jour., Feb. 16th, 1895.

There are two conditions connected with the *eyes* which commonly follow head injuries; the one is inequality of the pupils and the other is accommodative asthenopia. *Inequality of the pupils* is frequently seen and may persist for a long period after the accident. In my experience it is only found in cases in which there has been reason to suspect some macroscopic lesion of the brain and the larger pupil appears to be on the injured side of the head. *Accommodative asthenopia* frequently accompanies chronic headache, vertigo, depression, and other manifestations of nervous disturbance. The effort of ciliary accommodation is soon followed by fatigue. The patient usually complains of weakness or mistiness of vision; on attempting to read or to look at any objects closely headache is produced, the letters or objects appear to run one into the other, and sight seems to fail him. The ophthalmoscopic examination fails to detect any change in the fundi and usually no error of refraction is discoverable. If the patient happens to be hypermetropic or astigmatic the symptoms are more marked. In two cases complete blindness in one eye led to the discovery of optic atrophy at intervals of eight and 14 months after the accident; in both there had been the signs of fracture of the anterior fossa of the base. *Nystagmus* was met with in two instances. It was seen in one patient 19 months after a depressed fracture of the left parietal bone and in another three years after a compound depressed fracture of the left frontal region treated by trephining. In the latter case there was paresis of the right arm. In each case it was horizontal and unaccompanied by other ocular changes. Its significance is unknown.

Facial paralysis was found present in one case four years and in three cases about one year after fracture of the base. On the other hand, in nine cases in which this symptom had occurred after the accident it had disappeared at the time of the investigation.

Deafness was noticed in 12 cases in the first series and in three in the second series. It always occurred on the injured side of the head and in two cases was bilateral. It is probable that deafness is more often due to the injury having involved the middle or internal ear rather than the auditory nerve itself. In seven cases out of the 300 "post traumatic" otitis media occurred. Each case was carefully examined and there seemed no doubt that the otitis was directly referable to the injury. Three doubtful cases were excluded. In five of the seven cases there had been evidence of a fracture of the middle fossa. Three of the patients were children. Tinnitus was complained of in some cases and was associated usually with giddiness, rarely with deafness.

The condition of the superficial and deep reflexes is inconstant. The knee-jerks are most commonly exaggerated and this exaggeration usually lasts until complete recovery has occurred. In 40 cases in which symptoms were complained of the knee-jerks were exaggerated in 21, were normal in 10, and were diminished in eight.

The pulse after head injuries sometimes remains permanently slow with a tendency to intermission. In these cases complete recovery is rarely present and there is often a tendency to mental inertia.

There are numerous other conditions which may follow injuries to the head, to some of which I will now refer. It has long been known that these injuries may be followed by *glycosuria*; this may be temporary, appearing within a few hours of the accident and usually lasting for a few days only; or permanent, appearing after an interval of a few weeks or months. The former condition is common, the latter is rare. I met with no instance of traumatic glycosuria in series 1 and 2. In the third series is the case of a young officer who was under the care of Mr. G. R. Turner. He had been brought home from Egypt having sustained a severe fracture of the base followed by prolonged unconsciousness. Glycosuria was discovered six weeks after the accident and persisted; the patient's condition became extremely serious 12 months later. The urine contained about 8 per cent. of sugar and coma developed; for three days he was completely unconscious. Finally, however, he completely recovered, the urine becoming free from sugar 18 months after the accident. Only very occasionally does the glycosuria appearing after the accident persist for a long period; as a general rule, the later sugar appears in the urine the more pronounced and the more likely to persist is the condition. The precise explanation of the traumatic glycosuria is at present impossible. It has long been known that lesions of certain areas in the floor of the fourth ventricle produce glycosuria, but it is equally certain that lesions of many other parts of the nervous system may produce a similar result. This fact has been indisputably proved by experimental observations in animals. The clinical aspect of the question gives us but little help and although it appears that glycosuria most often follows fractures of the base and injuries to the back of the head the post-mortem observations in fatal cases have failed to reveal any constant lesions. We are therefore driven to the conclusion that the symptom possesses no localising value.

Traumatic hemiplegia may be primary, dating from the time of the accident, or secondary, appearing later after a variable interval. In the latter case it is due to cerebral sclerosis or softening involving the motor areas of the cortex. I have recently seen an interesting example of this late hemiplegia. The case was that of a man, aged 60 years, who sustained a compound depressed fracture of the vertex in the year 1861, a brick having fallen from a height on to the top of his head. He was operated upon and erysipelas followed. Later several pieces of necrosed bone came from the wound. His left leg was paralysed at the time of the accident but had recovered almost completely a few weeks after. In 1876 he noticed that the leg was beginning to become weak and to drag in walking. When seen last year there was a large depression over the upper part of the right parietal bone with a firmly adherent scar. The left leg was almost completely paralysed and the muscles were atrophied. There was also moderate paresis of the left arm. There appeared to be some blunting of the intellectual faculties but no other nervous effects. An instructive case of traumatic hemiplegia was admitted into St. George's Hospital under the care of Sir W. H. Bennett last year. The man had been struck on the head by a portion of a shell in South Africa 27 months previously. He was unconscious for nine days and left hemiplegia resulted; no operation was performed. The paralysis persisted and there had been severe headache and giddiness with impairment of memory and hearing. On admission a tender adherent scar was found over the right upper Rolandic area; the left leg was completely paralysed and the left arm partially. On operation the following lesions were found: thickening and adhesion of the pericranium, great thickening of the bone with an old fracture of its inner table, firm adhesion of the dura mater, and a blood cyst between the dura mater and the cerebral cortex. A large area of the bone was removed and the cyst was partially excised. Considerable improvement has since taken place in the movements of the arm but the condition of the leg is unaltered.

The pathology of certain of the conditions which I have described is obvious. The structural lesions connected with hemiplegia, motor aphasia, and disturbances of the cranial nerves, for instance, are well known and do not call for comment. I have already discussed the causation of the localised forms of cephalalgia. On the other hand, the pathology of many of the other symptoms which I have discussed is obscure and demands further research. I refer especially to generalised cephalalgia, vertigo, vomiting, and the various minor mental disturbances which owe their importance to their frequency. Some of these effects may be due to structural lesions, others are supposed to be the result of functional changes. In using the word functional I mean to say that we fail to find any anatomical or structural change to account for the symptoms and it is interesting to note that with the advance of knowledge many diseases formerly described as functional are now known to be structural. I admit that certain of the symptoms which follow head injuries may be due to functional disturbances but I believe that in the larger number of cases definite organic changes exist which are either direct or indirect causes of these symptoms.

It is not generally recognised that in the great majority of head injuries accompanied by loss of consciousness definite organic lesions occur. Pure concussion, I believe, is extremely rare. It is argued that we have no evidence of the presence of organic lesions in cases of mild concussion. But there is a certain group of cases which gives us very definite evidence. I refer to those accidents in which the patient dies from thoracic or abdominal injury and in which there has also been some slight cerebral injury producing a short loss of consciousness. I collected ten cases of this nature, taking those in which there was a clear history of loss of consciousness for less than five minutes. In eight of these the necropsies revealed some definite intracranial lesion; in four there was cortical contusion, in one there was cortical laceration, and in all of the eight cases there was some degree of intrameningeal hæmorrhage. Further, the post-mortem examinations in cases where death follows at some more or less remote period after the receipt of the head injuries show that all but the slightest of the contusions and lacerations of the brain are followed by permanent changes. The most conspicuous of these changes is adhesion of the damaged part to the bone, an adhesion which is frequently so intimate that the brain tears away on attempting to separate it from the bone. In most cases we also find thickening of the meninges and discolouration of the cortex from old extravasated blood. The fact that mental disturbances following injuries to the head may disappear in time is no proof that they are not due to structural changes. Motor aphasia may be cured by the corresponding centre on the opposite side of the brain taking up the function of speech, and it is highly probable that when the centres of any of the intellectual faculties have been injured the function may be restored by being represented in other parts to the brain.

The diagnosis will sometimes present difficulties and one cannot always be certain that the symptoms attributed to the head injury are really due to that injury. After accidents of this nature the patient is on the watch for after effects and may now notice some condition previously overlooked. An excellent example of this is found in ocular defects and in several cases I have found that defective vision complained of has been due to refractive errors which must have existed for some long time previously. Further, previously existing pathological conditions may be intensified by an injury to the head. In order that the features of the case may be thoroughly grasped it is necessary to examine the patient on three or four occasions at least and when possible to see the relatives, friends, and employers. In this way we shall be able to estimate correctly the significance and importance of the various symptoms and signs present.

The elements of malingering and exaggeration must always be remembered. It may be extremely difficult to determine whether the patient is honestly suffering from the symptoms of which he complains. Yet the malingerer will often reveal himself by the exaggeration of certain symptoms or by telling us of troubles which we know do not follow head injuries. I have noticed that such persons almost invariably complain of pain and more especially of tenderness in any scar that may be present. The facial aspect will tell much to the experienced eye. Cephalalgia and insomnia, for instance, are conditions which will inevitably impress themselves on the patient's expression. The red-faced, cheerful-looking individual who tells one that he has a continued headache and has slept but little since his accident may confidently be described as a perverter of the truth.

The utmost care must be taken to exclude hysteria, simple neurasthenia, and constitutional conditions such as syphilis and gout. Local causes for the head symptoms must [illegible] the mouth, nose, ears, and eyes [illegible] kind or other are common in [illegible] a tendency on the part of the parents to attribute to these injuries any mental or other condition which may arise months or even years after. I have recently seen two children who were brought to me as suffering from the after-effects of head injuries. A careful examination, however, convinced me that all their symptoms resulted from nasal obstruction and this opinion was confirmed by the improvement which followed the removal of post-nasal growths. It has been suggested that when once a patient has apparently made a complete recovery from a head injury he will remain free from any further effects and that if head symptoms develop at some later date they are due to some other cause. My experience is that this is correct in the great majority of cases but that exceptions may undoubtedly occur. I have met with two instances in which chronic cephalalgia has developed as the result of osteo-sclerosis at the site of the injury after a prolonged interval in which the patients had been free from symptoms of any kind. Another striking example is afforded by a case to which I shall refer in my next lecture, in which a cerebral abscess following a depressed fracture remained completely latent for a period of ten years. As a general rule, however, I believe that when a patient has been completely free from symptoms for a period of six months any symptoms arising later will be due to some other cause. A head injury, of course, may increase a predisposition already existing and in particular the resulting susceptibility to the effects of alcohol may render the patient more liable to mental disturbances.

The prognosis in these cases must always be [illegible] and should never be given until [illegible] fully considered and until the [illegible] several occasions. At least a year is required for complete recovery in most cases of severe head injury and a prognosis given before that period is very likely to prove erroneous. The various etiological factors to which I have drawn attention will help us in determining the prospects of cure. It is clear that our efforts are more likely to meet with success in the cases in which the previous treatment has been imperfect than in cases which have failed to respond to thorough treatment. The means available for treatment must be reckoned with. The process of cure may involve much time and expense which many patients are unable to afford. When a patient comes for treatment for the after-effects of a head injury it is advisable at once to inquire whether he is bringing an action for damages or not, for the prognosis varies greatly with this factor. When the patient has been placed under treatment we are soon enabled to judge the prospects of ultimate recovery. In many cases the state of the temper is a good guide to the rate of progress and it is a particularly hopeful sign if the patient is conscious of his irritability and is anxious to overcome it. The return of natural sleep is another encouraging sign.

TREATMENT.

I will now proceed to consider the *general treatment* of these cases. In few other conditions are such careful consideration and such constant supervision required, and upon the treatment adopted depend the ultimate recovery and the future happiness of the patient. I wish to point out most emphatically that the majority of these cases are curable. But their cure requires the greatest care; it requires discrimination and it requires time. It cannot be brought about by a single examination and a hastily written [illegible] a careful study [illegible]ondition of each [illegible]he management [illegible] to the varying [illegible]e dealing. Too often these patients are put on mercury or sent on a sea voyage, with a vague hope that time will see an end to their symptoms, and the usual result is that symptoms persist; valuable time is thus wasted, for the longer the symptoms have persisted the more difficult is their cure. In the well to-do and in those who can afford to undergo the correct treatment the prospects of complete recovery are good; in the out-patient department of our general hospitals when the patients cannot or will not submit to the necessary treatment the results are very unsatisfactory. In a majority of the cases the question of operation does not arise, but whether operation is performed or not the general principles of treatment will be the same.

There is no part of the treatment which is more essential to success than the securing of mental and physical rest. It is impossible to emphasise too strongly the absolute necessity of prolonged mental rest. It has already been pointed out that where the period of rest after head injuries is short incomplete recovery almost invariably results, and it is as necessary in the cases with which we are now dealing as during the period immediately following the head injury. It is important at the outset to impress upon the patient the need of time and patience for successful treatment. He will often not realise the gravity of his troubles and the possibility of permanent nervous disturbance. In the medical profession, too, it is not sufficiently recognised that the period of treatment must be measured by months rather than by weeks. The following are the general measures which I should recommend for the more serious cases in which chronic headache, depression, and irritability are marked features. To insure complete rest for the nervous system it is necessary that the patient should be removed from all sources of worry and excitement. The word "vegetation" describes most expressively the mental condition under which we desire to place him. Sometimes this can be managed at his home; but at home it may be impossible to free his mind of business troubles and much harm may be done by injudicious relatives or friends. We must be guided by circumstances. If the symptoms are severe and if the patient is well-to-do he should be treated in a private nursing home, and it will be thus possible thoroughly to control the management of the case. In other cases our object may be best effected by sending the patient to some quiet country village or farmhouse; let him vegetate here for some weeks or months, doing nothing which requires the slightest mental exertion, living in the fresh air as much as possible. He must not, however, be isolated, for isolation will do more harm than good. Let him be put in charge of a medical man or of friends who will take care to see that the details of the treatment are conscientiously carried out. For the more serious cases life at the seaside can rarely be recommended, for it is difficult to obtain the requisite amount of quietude. In no circumstances should a patient be sent to travel or to go for a sea voyage, if for no other reason than that he will be no longer under the supervision of the surgeon. For cases in which the after-effects are slight a stay at the seaside will be indicated. As improvement advances an increasing amount of exercise may be allowed; rowing is one of the best forms of exercise, as it involves but little exertion. Sea-bathing must certainly be prohibited. Certain other forms of exercise often indulged in by these patients must also be mentioned to be condemned: these are bicycling, motoring, and playing cricket or tennis in the sun. The main principle is that the patient must be strictly kept from any mental or much physical exertion; he must never be allowed to get tired. With mental quietude should be combined high feeding and general massage. Feeding must be pushed to apparent excess; food must be given in large quantity and frequently, and this will do much to favour the recovery of a healthy nervous tone. The occurrence of attacks of vomiting is no contra-indication to high feeding, for, as I have said, the vomiting is cerebral and not gastric in origin. Alcohol in any form must be strictly prohibited. Massage will assist in restoring the reduced nutrition and the increasing weight of the patient will be proof of its value.

The *drugs* which have been used in these cases are innumerable. I have never seen any good follow the use of bromides; the patient is already depressed and in low spirits and anybody who has ever taken bromides will appreciate their depressing effect, which is the last thing that these patients desire. In fact, the use of bromides will almost invariably aggravate the very symptoms which we wish to relieve. The epileptic undoubtedly improves under their use In many mental and nervous diseases bromides are invaluable. For the sequelæ of head injuries their use is illogical and attended with harm. Iodides, again, rarely do good and are depressing but not so depressing as bromides. Strychnine should be avoided. Mercury in my experience is the only drug which gives these patients any lasting relief and even it will sometimes fail. Its mode of action is quite unknown; its use is entirely empirical. I have seen it do good again and again and therefore recommend it. I have usually prescribed it in the form of grey powder in combination with Dover's powder; one grain of each may be given three times daily and the dose then gradually increased. There is one point which must always be attended to whilst this drug is being used: the patient's weight must be taken regularly each week. In the majority of the cases we are discussing it will be found that the general nutrition is much impaired and it will be found that weight will steadily increase as improvement in the symptoms takes place and then remain stationary when the normal weight is reached. If at any time during the treatment weight is lost the dose must be lessened or the drug discontinued. The patient's weight is thus an accurate indication of the amount of improvement that is taking place. Some authorities state that mercury is best tolerated for a long period in the form of the tannate. I have used this preparation in two or three cases but have not seen enough of it to give a definite opinion.

For the temporary relief of headache, phenacetin, antipyrin, antikamnia, or aspirin should be used. I have found citrophene in doses of five grains often useful. If one drug fails another should be tried, for there are very few people to whom one of them at least will not give some relief. Unfortunately, however, the relief is usually but short. Localised headache may sometimes be greatly relieved and sometimes cured by that old-fashioned and much neglected remedy, the seton. It should be applied close to the site of pain and be used for three or four weeks continuously.

The insomnia which is so frequently present can often be treated satisfactorily without resource to drugs, but their use is justified in severe cases, for regular sleep is of the first importance. One of the most satisfactory drugs is veronal and this may be ordered in ten-grain doses each night. Small continuous doses are given, so that the physiological effect is gradually produced. Very little result may be noticed for the first few nights, but in two or three weeks the patient will probably be sleeping regularly and well. The dose should then be reduced to five grains each night and in a fortnight or so left off. There is one other measure to which I must refer which is of the greatest value in soothing the irritability and in allaying the depression and that is the oft-abused pipe. Smoking does no harm in these cases; it usually does great good by quieting the nervous system. Let the patients, then, smoke as much as they wish.

I will now proceed to discuss the *operative treatment* of these common conditions which follow injuries of the head. I shall not refer here to traumatic epilepsy and traumatic insanity as these will be dealt with in my next lecture. We shall have to consider the indications for operation and the nature of the operation to be performed. I must first draw attention most emphatically to the fact that the operation of trephining *per se* involves practically no risks. It is, in fact, one of the safest and simplest operations in surgery. It is now being recognised in the profession that the risks of an exploratory laparotomy are practically negligible, but it is not yet recognised that the same is true of simple trephining. Unfortunately, the wide and free access cannot be obtained by trephining as by abdominal section, but localisation in cerebral surgery is as accurate as in abdominal surgery, and if larger openings be made into the skull we can usually reach the diseased part. I would urge, therefore, that trephining should be performed far more frequently and at a much earlier date than is usually the custom for the following reasons. The operation is practically devoid of risk when, as is often the case, the dura mater is not incised and in any case it is an extremely safe one. The second and more cogent reason is that the results are most excellent and constant in properly selected cases.

I shall speak mainly of the treatment of cephalalgia, for in the cases with which I am dealing it is this symptom which most often calls for operation and the removal of its causes will usually result in the cure of associated mental disturbances. In discussing the operative relief of cephalalgia it is necessary to bear in mind the different varieties of this condition. The generalised forms of headache are usually amenable to non-operative measures and those which prove rebellious can only be treated surgically if some distinct localising lesion be present—that is to say, generalised headache without any local lesion is not likely to be cured by operation. Supposing now that there is diffuse headache and that a scalp wound or evidence of an old fracture is present what is to be done? In such cases I believe that the best practice is to carry out carefully the non-operative treatment to which I have already referred for a period of six months and if at the end of this time no improvement has taken place then the site of the injury should be exposed and dealt with according to circumstances. In the localised forms of cephalalgia the treatment is more clear and operation is indicated in all cases in which pain is intense and has proved uncontrollable by milder measures. In the neuralgic variety the whole scar should be freely excised down to the bone, pericranium being included if it appears in any way altered. The most satisfactory cases are those in which osteo-sclerosis is the cause of the pain and I have seen several cases promptly and completely relieved by trephining. A large flap is turned down and the diseased bone is very freely removed: if the dura mater is thickened it should be cut away; the scalp flap is then replaced. When the localised headache is not due to lesions in the scalp or to thickened bone the operation is of an exploratory character and its nature will be determined by circumstances. The lesions met with and the treatment to be adopted are the same as in cases of traumatic epilepsy. In many instances we shall find unsuspected depressions of the bone; sometimes these will be found to have involved the inner table only, having presented no external evidence of their existence. Splinters of bone may be discovered pressing inwards or actually penetrating the dura mater. We must never omit to explore the inner surface of the bone by passing a probe between it and the dura mater for some distance around the trephine opening. Thickening and adhesions of the cerebral membranes are best treated by excision of the part of the membranes involved; any measure short of this will fail. Intrameningeal cysts containing blood or serum may be found but can seldom be diagnosed before the dura mater is opened. The smaller cysts can often be removed entirely; with the larger ones this is impossible. In the latter case the cyst should be opened, its walls cut away as far as possible, and the remaining part treated by gentle scraping and the application of a solution of 1 part in 10 of carbolic acid. Unless this is done a persistent sinus may follow. If in the course of the operation we have reached the cortex of the brain without finding any definite lesion to account for the symptoms the cerebral cortex must be carefully scrutinised and palpated. Cortical cysts are occasionally met with; if superficial they are readily recognised, if deep we find some localised tumidity, impairment or absence of the cerebral pulsation, and a feeling of increased resistance on palpation. In doubtful cases a long narrow scalpel should be introduced directly into the region of the suspected cyst. The other lesion which may be found comprises scarring and sclerosis of the cortex. In such cases it has been proposed that the diseased area should be excised but I believe that more harm than good will usually be done. If as the result of the operation no lesion of any kind is found we have at least the satisfaction of knowing that cure of the symptoms may follow, although we can apparently point to no step in the operation which is responsible for this result.

I must briefly refer to one or two of the most general steps of the operation. First, the simple trephine is undoubtedly the best means which we possess at present for opening the skull. Numerous other mechanical and electrical devices have been invented to take the place of the trephine but these all fail in one essential point: the sense of touch is lost by their use. In addition they are complicated, difficult to keep aseptic, and very liable to get out of order.

Secondly, large trephines only should be used and all trephines with a diameter of less than one inch should be abolished for these operations. It is essential for success to start with a large opening. If a half-inch crown of bone be removed it is impossible as a rule to deal adequately with the diseased parts; whilst to start with a small opening and to enlarge it afterwards is a slow and unsurgical method. For general purposes a trephine with a diameter of one and a quarter inches is most serviceable. There is one other instrument which is indispensable in these operations and that is Hoffmann's bone-cutting forceps. They are the most useful means of rapidly enlarging the trephine opening in any required direction.

The third point which I wish to bring forward here, is that if it is decided to deal with any extensive lesion of the brain itself the operation must be performed in two stages. The only argument which I need adduce in favour of this proposition is that the mortality in these operations if completed in one stage is very high, patients being unable to withstand the serious shock resulting, whilst if the operation be performed in two stages comparatively little shock follows. At the primary operation, then, a large opening in the skull, usually about three inches in diameter, is made and the flap which has been raised is sutured into place again. A fortnight later the flap is turned down and the diseased area is dealt with.

Lastly, there is the question of adhesions between the brain and the overlying tissues after operation. When thickened and adherent meninges have been excised it is clear that extensive adhesions may form and a strongly contracting cicatrix may result. The objects of the operation will thus be defeated and symptoms will recur. It is useless to talk about the prevention of adhesions: they will form in spite of anything that may be done. Our aim must be to reduce them to a minimum. In order to effect this various substances, such as gutta-percha tissue, egg-membrane, and gold foil, have been placed between the cortex and the structures lying over it. Of these I believe that gold foil is the best at the present time. In the future we may discover some more natural tissue for the purpose. The gold foil is cut very slightly larger than the opening in the dura mater and is then carefully inserted between the brain and the cut edges of the dura mater, the greatest care being taken to leave it lying quite smoothly. The bone, of course, is not replaced.

To sum up briefly, the following are the conclusions to which I have come in regard to treatment. 1. In rather more than half of the cases cure may be brought about by medical measures; prolonged mental rest and the proper administration of mercury are the essential points. 2. In a few of the cases the symptoms are mainly due to chronic osteo-sclerosis and such cases may be almost certainly cured by trephining. 3. In the remainder of the cases the symptoms are more persistent and do not yield to general measures or to the removal of thickened bone only. I believe that in such cases these symptoms are the reflex results of lesions or irritations of the dura mater; and if the injury has involved the vault of the skull cure can be effected promptly by excision of the thickened or adherent dura mater and removal of any other source of irritation which may be present.

A CASE OF
RUPTURE OF A TUBAL PREGNANCY ON THE NINETEENTH DAY AFTER CONCEPTION AND TEN DAYS AFTER THE UTERUS HAD BEEN CURETTED.[1]

BY WILLIAM DUNCAN, M.D., F.R.C.S.,
OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE patient, aged 27 years, was married in 1900. She consulted me in October, 1901, for menorrhagia. The periods, which commenced at the age of 12 years, were quite regular, lasting four days, until the early part of 1901, when they began to increase in amount, with pain, the passage of clots, and a muco-purulent intermenstrual discharge. The patient was a healthy looking but pale woman of very active temperament. On examination the uterus felt a little enlarged, was somewhat tender on palpation, in normal position, and freely mobile. Nothing abnormal could be felt in either the lateral or posterior fornices. Per speculum the os uteri was eroded and some purulent discharge was seen exuding from it. I diagnosed fungous endometritis and recommended that the uterus should be curetted. The patient went into a nursing home and I dilated the uterus (under anæsthesia) up to No 14 Hegar and scraped away a very hypertrophied endometrium; the uterus after having been swabbed out with liquor iodi was packed with iodoform gauze for 48 hours. At the end of that time the gauze was removed and a vaginal douche of a 1 in 4000 solution of perchloride of mercury was ordered to be given night and morning whilst the patient remained in the home (this is my usual method of treatment after curetting the uterus). The patient made a perfectly uneventful recovery and returned home well after three weeks. I saw nothing more of her until the beginning of last November (1903) when she again consulted me for a recurrence of the menorrhagia. She then informed me that she had had a miscarriage at the third month at Christmas, 1902, and that since that time the periods had been excessive and with clots. Since the miscarriage *she had never missed a period*. On examination I found a similar condition of things to that present when she consulted me in 1901, except, perhaps, that the uterus was somewhat more bulky than on the former occasion, but nothing whatever abnormal was detected in either fornix. As the next period was due in a few days it was decided that the curettage (which I again advised) should be deferred until a couple of days after the period had ceased. This occurred on Nov. 14th after a week's loss; accordingly, on Nov. 16th I went to the patient's home and with the assistance of Mr. Arthur John Hogg of Ealing (under whose care the patient had placed herself and

---

[1] A paper read before the British Gynæcological Society on Feb. 11th, 1904.

"hyperæmic" and "fibrous" varieties (corresponding to the "transient" and "protracted" varieties of this paper). He does not, however, recognise a "malignant" class, though this has recently been done by Poynton and Paine in a paper on malignant rheumatic endocarditis.[5]

The following cases are quoted as representative of the transient, protracted, and malignant varieties of rheumatic infection of the joints, the heart, and the brain. Arthritis is perhaps the best to begin with, because it is the most familiar of all rheumatic lesions. Indeed, till recent years the word "rheumatism" stood in the first place for all forms of articular pain and after that unfortunately became a "rubbish-heap" sort of word, to which all sorts of pains of unknown pathology were consigned. This error is passing; still to the majority the term "rheumatism" calls up the picture of a particular form of multiple arthritis and not of a definite systemic infection.

The transient degree of arthritis is so familiar that one scarcely need describe a particular case. A girl 18 years of age falls ill rather suddenly with pains all over her, perhaps preceded by a sore-throat; she becomes feverish and has to stay in bed. Her joints are found to be slightly swollen, pink and hot, and very painful whenever they are moved. Those first affected get well while others are freshly involved. There is a notable similarity between such a condition and the polyarthritis produced by inoculations of animals with micrococci in the experiments of Wassermann and Malkoff,[6] Poynton and Paine,[7] Ainley Walker and Beaton,[8] and Shaw.[9] There are free acid sweats and the tongue is thickly coated with a white fur. She is given salicylate of sodium; the temperature falls from 101° F. to normal in two or three days and in five or six days she is free from pain. This is called recovery; but one must bear in mind the great commonness of relapse and of recurrence in after years. These seem to indicate a less complete triumph on the part of the body than would at first sight appear and at the same time form a link with the group of cases next exemplified—the protracted forms of rheumatic arthritis.

Many patients who have had repeated attacks of acute rheumatic arthritis show permanent thickening of the joints, ulnar deviation of the fingers, &c. There are between the acuter pains of the rheumatic outbursts a slight, but none the less real, constant disability and stiffness, with occasional aches and pains, suggesting that perhaps the recurrent acute attacks are merely the bursting into flame of an infective process all the time quietly smouldering. This kind of thing was well exemplified by the following case which was recently treated in St. Mary's Hospital under the care of Dr. Cheadle.

CASE 1.—The patient, a man, aged 21 years, had rheumatic fever for the first time in November, 1901, while he was serving in South Africa; there was no preceding gonorrhœa, dysentery, &c. He was invalided home with "rheumatic fever and V.D.H." He went home and rested a month. All this time he had rheumatism, mostly in his toes and fingers. Then he went to work but the pain in his feet compelled him to give this up. He rested for a week and then tried to work once more. Since then he has had 15 situations, the longest being held for six weeks. Each had to be given up on account of pain and swelling in the feet. His hands were also affected in the cold weather. Three weeks before admission he had a severe attack, beginning in the feet and knees and spreading to his fingers. This was, however, by no means the worst attack of all. There were fever, malaise, and sweating as in all previous exacerbations. On admission various joints were swollen and were pink and painful. Ten days later these acute signs had gone but the metacarpo-phalangeal joints of the forefingers and middle fingers of both hands showed thickening with crepitus and stiffness, especially in the forefingers. Similar but rather less marked changes were observed in the proximal interphalangeal joints of the same fingers, and still more definitely were they present in the corresponding joints of the corresponding toes, which were very stiff and much deformed. There were interosseous wasting in the hands and in the toes fine rhythmic tremor on attempts at flexion. He had early mitral stenosis.

Here, then, is a case illustrating the running fight between joints and micro-organisms and at the same time throwing light on the pathology of the type of crippling polyarthritis met with chiefly in young and middle aged women. Of these there are, however, cases in which the destruction of articular surface is greater than could be achieved by infection of the degree of intensity represented by the case just described. It has frequently been suggested[10] that some at any rate of these cases of extreme arthritis deformans are really due to a destructive rheumatic invasion and the following case goes to support that suggestion.

CASE 2.—A woman, aged 42 years, was admitted to St. Mary's Hospital under the care of Dr. S. P. Phillips after being for three weeks in bed suffering from painful swelling of the feet and the legs. At the age of 21 years she had had rheumatic fever but between then and now she had suffered in no degree from joint pains or from anything else except confinements. There were free acid sweats; the only cardiac sign was a transient systolic murmur at the apex, and there was slight pyrexia. The joints especially affected proved to be the metacarpo-phalangeal joints of the forefingers and the middle fingers on both hands. These were hot, pink, and swollen, with thickening, apparently bony, and consequent ulnar deviation of the fingers. The corresponding thumb-joint was affected and there was considerable interosseous wasting. The right wrist-joint contained fluid and showed very distinct bony thickening and crepitus. The metatarso-phalangeal joints of the great toes were also thick and showed lipping. In the shoulder-joints there appeared to be much bony overgrowth with loss of mobility. The lower border of each patella and the outline of each ligamentum patellæ were obscured by what seemed to be thickened synovial tissue. Salicylate was effective in removing the signs of acute disease though other means of treatment had been unsuccessful.

In this case, then, a patient's joints, infected apparently by rheumatism, underwent deforming bony changes in less than a month. In connexion with this it is useful to remember that small diplococci were found in the osteo-arthritic joint of a man who died from carbolic acid poisoning and that intravenous injection of such cocci set up rheumatoid changes in rabbits.[11]

So far, therefore, we have seen that rheumatic infection can produce a transient arthritis, a protracted arthritis, and a rapidly deforming arthritis which may well be called malignant. Similar degrees may be recognised in the results of rheumatic infection of the heart. For the present purposes it will be well to separate endocarditis, myocarditis, and pericarditis while fully recognising their actual interdependence.

Taking the endocardium first, one has to acknowledge the impossibility of speaking decidedly on the question of the occurrence of transient forms of rheumatic infection. Still, it may be worth while to remark that the disappearance of murmurs apparently due to acute valvular endocarditis has led many (including Cheadle,[12] Byrom Bramwell,[13] and Sansom[14]) to suppose that transient rheumatic endocarditis does occur. The following case may be quoted as an example.

CASE 3.—A boy, aged eight years, was admitted to St. Mary's Hospital under the care of Dr. Phillips on June 3rd suffering from rheumatic arthritis which quickly subsided. On admission he was found to have mitral disease and during the three weeks subsequent to admission he developed well-marked signs of aortic incompetence. The temperature ran between 99° and 102° F. till June 22nd, when it fell to, and remained at, normal. On the 27th it was found that the previously distinct aortic diastolic murmur could no longer be heard and I believe it did not return again.

It is, of course, easy to find cases of protracted rheumatic endocarditis where the severity of the process and the gravity of the permanent results are proportional to the irrepressibility of the infection. A case of unusual interest will be used as illustration of this group.

CASE 4.—The patient was a female, aged 26 years, who was admitted into St. Mary's Hospital under the care of Dr. D. B. Lees, with rheumatic pains of a few days' duration. She had had rheumatic fever at 20 and at 24 years of age. The arthritis improved under treatment; once or twice, however, during her stay in hospital it relapsed feebly. She also had pleurisy on the left side, with pain and rub, from time to time, but by no means constant (this probably indicated a quiet pleuro-pericarditis, but no definite signs of pericarditis were found). There was fever, at first remittent and later intermittent, extending over two months. Meanwhile an aortic diastolic murmur appeared (being first noticed while there was fever, but no arthritis or pleurisy) and gradually became more and more definite; the pulse at the distinctive collapsing charac great anæmia, and occasion. time the endocarditis was thought malignant in degree but her fever subsided and she was able to go back to her friends. This case, then, represents a prolonged fight between valve and micro-organism, in which the valve was, for the time at least, victorious but suffered irreparable damage.

The next case is one of malignant rheumatic endocarditis.

CASE 5.—A man, aged 22 years, was admitted to St. Mary's Hospital suffering from feverishness and sweating. He gave a history of acute rheumatism at the ages of six and ten years. At 16 years of age he became short-winded and two months before admission he gave up work, went short of food, and got wet. His joints became painful and kept him in bed for three weeks, after which he was admitted to hospital under the care of Sir William H. Broadbent. There were free sweating and irregularly hectic fever; he was clearly very ill and had signs of mitral disease. Two days before death he lost power in his left limbs; this was followed by a gradual loss of consciousness. Post mortem the endocardium of the left auricle was found to be ulcerated in one patch. There were thick masses of fibrin on the mitral valves and many of the chordæ tendineæ were torn. There were old infarcts in both kidneys and recent ones in the right lung and in the brain. The latter had given rise to aneurysm of the right middle cerebral artery and subsequent hæmorrhage. Similar changes have been found in rabbits dying after experimental inoculation with the micrococcus of rheumatism.[15]

Myocarditis will only receive brief consideration here as it is so intangible clinically. Of the transient type the following will serve as an example.

CASE 6.—A woman, aged 29 years, who was admitted to St. Mary's Hospital under the care of Dr. Lees for her first attack of acute rheumatism, had normal cardiac signs till several days after admission, when the sounds became poor and the impulse diffuse and increased in area to the left. The cardiac dulness was also increased to the left and the pulse became slow and irregular. A systolic murmur of rest, &c., all I can offer no wever, exist in association with mitral and with pericardial fibrosis due to rheumatism.[16] No doubt these myocardial changes must make a great difference to the patient's power of compensation in valvular disease, but at present our methods are too coarse to enable us to appreciate this factor clinically.

Can myocarditis of rheumatic origin cause death of itself? Herringham has reported such a case.[17] A patient, who acute rheumatism with old ddenly in St. Bartholomew's were found minute valvular vegetations and pericarditis of the slightest degree. The cells of the cardiac muscle showed cloudy swelling and fatty change, with considerable overgrowth of the connective tissue. This is as much as one can say of myocarditis from the present standpoint. In the pericardium, however, it is easier to trace the various grades clinically.

The following case is an example of transient rheumatic pericarditis, which is common enough, though, in children especially, the mischief done is often not so transient as it seems at first to be.

CASE 7.—A man, aged 35 years, was admitted to St. Mary's Hospital under the care of Dr. Cheadle. He was taken ill on June 29th, 1900, with joint pains; on July 4th pain in the chest with dyspnœa supervened and on the 7th he was admitted. He was feverish and sweating; his joints were still swollen and painful. His cardiac dulness was increased both ways and there was a loud to-and-fro rub all over the præcordium. There were signs of consolidation at the left base. Within a week both temperature and cardiac signs were normal and he was discharged on July 23rd.

Examples of progressive pericardial fibrosis are, unfortunately, common among rheumatic children. The following is an illustrative case.

CASE 8.—A girl, aged 12 years, was admitted under the care of Dr. Cheadle in July, 1902, for dyspnœa beginning three weeks after articular rheumatism. She also had chorea, for which a year previously she had been in St. Mary's Hospital; on that occasion her heart was normal. On admission in July, 1902, her heart was very big; there were a rough præcordial rub and a mitral systolic murmur. The veins in the neck were swollen and pulsating. There was fever in bursts—a type of pyrexia rather characteristic of rheumatic endo-pericarditis. The rub disappeared, otherwise the heart remained the same. The general condition improved and she went out. In April, 1903, she came back with intense dyspnœa and cyanosis, enlarged liver, &c. There was an aortic diastolic murmur and a pleuro-pericardial rub was heard several times for a day or two at a time. Fever was persistent and there were crepitations at the left base. She died suddenly 16 days after admission. Post mortem there was found to be universal adhesion with thickening of the pericardium and only slight recent endocarditis with scarring of the mitral and aortic valves. The myocardium, especially of the right ventricle, was pale and flabby. There was some slight recent pleuro-pericarditis on the left side of the heart and the mediastinal glands were enlarged. In a similar case Dr. J. F. H Broadbent found small cocci—corresponding in staining, &c., with the micrococcus rheumaticus—in these enlarged glands.

This, then, was a case of protracted rheumatic pericarditis where an acute outburst proved the "last straw" to a heart hopelessly crippled by its fibrous prison. A case of malignant rheumatic pericarditis comes next.

CASE 9.—A girl, aged 18 years, was admitted on Nov 24th, 1880, to St. Mary's Hospital under the care of Sir William Broadt arthritis of five days years previously sounds being distant. There were erythematous patches on her legs and a trace of albumin in her urine. The arthritis persisted. There was delirium at night and soon a loud pericardial rub was heard. The temperature kept high and on Dec. 4th she died. Post mortem the pericardial sac was found to contain two ounces only of turbid fluid. Both pericardial layers were swollen and the opposed surfaces were plastered with fibrin. Immediately beneath the visceral pericardium the heart muscle was pale. Death in this instance must have been due to toxæmia and to yielding of the sodden pericardium allowing of acute dilatation.[18]

Our scale of cardiac rheumatism is now as complete as it can be made. It has not been possible to speak positively, from clinical standpoints, of the occurrence of transient endocarditis or of myocardial fibrosis, but it has been shown that the one perhaps occurs and that the other is found post mortem.

Now, lastly, is it possible to trace this gradation of results of rheumatic infection of the brain—i.e., of rheumatic chorea? The transient case of chorea is always with us, though, as in the joints and the brain, the infection often proves more enduring than is at first expected. It is quite common to get a history of chorea in the earlier years of young adults with mitral stenosis, one definite attack occurring without relapse or recurrence. Further, many children with rheumatism are in a "choreiform state"; the fingers are unsteady and hyperextended when held out straight; the face is unduly mobile and so are the emotions. All these signs may subside and never return or they may in the course of days, weeks, or months, develop into a full-blown chorea. The chronic cases are as familiar. One example is that of a boy who was recently under the care of Dr. Lees both at the Hospital for Sick Children, Great Ormond-street, and at St. Mary's Hospital. He had had choreic movements continuously for a year and according to his mother for over 18 months. Another continuous case is that of a girl, aged 11 years, who had chorea, arthritis, and endocarditis in February, 1903. In April she had very slight twitchings of the hands and the face. In June and September she had well-marked chorea and again in January, 1904. This waxing and waning of symptoms in a chronic course are very characteristic of these protracted forms of rheumatism; compare the case of pericardiac fibrosis described just now and the outbursts of fever with effusion into osteo-arthritic joints which form the milestones of such cases.

[18] A paper by Dr. W. Hale White, Guy's Hospital Gazette, November, 1903.

Malignant chorea is happily rare. Death is usually due to cardiac complications; however, here is a case in which the cerebral lesion was responsible for the fatal issue.

CASE 10.—A girl, aged 18 years, was admitted to St. Mary's Hospital under the care of Sir William Broadbent on May 16th, 1887, suffering from chorea. This had been preceded by several weeks of rheumatic polyarthritis—her first attack. The chorea was very severe but she was at first able to swallow food. There was delirium with incontinence of urine and fæces. The arthritis persisted but there were no signs of cardiac disease. The temperature steadily rose and she died on May 30th, refusing food for the last two or three days. The post-mortem examination showed slight aortic valvulitis, the surface of the brain and the choroid plexuses were congested, there was an excess of cerebro-spinal fluid, and on the under surface of the right lobe of the cerebellum some recent lymph was found.

Many observations on the changes found after death in the brain of choreic patients are now on record, the general trend being to show that extensive microscopical change is present when little or no abnormality can be detected by the naked eye. The case just narrated, which may fairly be called one of malignant chorea, completes the requisite series of cases which go to prove the truth of the proposition with which this paper began—that clinically there are certain characteristics of rheumatic infection and its results, whether the infection be of joints, of heart, or of brain. These characteristics are—two extremes of severity, transient and malignant cases; and between these extremes a complete gradation of protracted cases, in which an imperfect resistance on the part of the infected organ or tissue leads to connective-tissue increase of a permanent and crippling nature. These protracted forms are punctuated by more or less frequent exacerbations.

The rest of this paper embodies a suggestion with some fragmentary evidence in its favour. The suggestion is this: that in many cases of rheumatic infection the organism persists in the infected tissue after all obviously inflammatory signs and symptoms have disappeared in a comparatively but not absolutely harmless state, capable of re-exaltation of virulence in favourable circumstances. The facts forming the basis of this proposition may be summed up as follows.

1. It is common to see a woman 35 years of age with mitral stenosis who has had rheumatic fever at 15 or 20 years of age without recurrence. The symptoms of cardiac disease begin some years after the arthritis. Necropsy shows extreme fibrosis of the mitral curtains. Now it is hardly likely that the rheumatic fever laid down, so to speak, a definite dose of fibrosis, the great increase of which is to be ascribed solely to the restlessness of the valves and the mechanical strain to which they are subjected. It is more satisfactory to postulate chronic irritation of the valves by organisms of lowered virulence persisting therein.

2. A case of the above nature sometimes blazes forth into a state of malignant endocarditis. This is usually ascribed to reinfection of previously scarred valves. The following case suggests rather that organisms persist in the fibrous valve and, under conditions lowering the patient's resistance, undergo exaltation of virulence with malignant results. A female, aged 20 years, who had had cardiac symptoms for 12 years, was admitted to St. Mary's Hospital under the care of Dr. Lees after a fortnight's illness. She had had rheumatism and chorea but not recently. Up to admission she was suckling her first child. She was very pale and weak. The physical signs were those of mitral stenosis, but her symptoms were graver than the signs and there was irregular pyrexia with wide daily excursions. The post-mortem examination showed infarcts of the lung, the spleen, and the kidneys, without suppuration; recent and old pericarditis slight in degree; old mitral stenosis with massive vegetations on mitral and aortic valves, chordæ tendineæ, and left auricular wall. These vegetations contained swarms of micrococci, apparently corresponding to the micrococcus rheumaticus as it is described by the authorities mentioned above.

3. Relapse is common in rheumatic fever, commoner even than in enteric fever, occurring in about 20 per cent. of all cases.[19]

4. Rheumatic affections tend also to recur at intervals too long to allow them to be called relapses. Thus, a youth, aged 19 years, with acute rheumatic arthritis and aortic incompetence, had had rheumatic fever when he was 12 years old and chorea a few months later. At 13 years of age he again had rheumatic fever and his heart was affected. At the ages of 14 and 16 years he had further attacks and several milder attacks between the ages of 16 and 19 years. If this kind of story be due to repeated reinfection it is without parallel (not excepting lobar pneumonia) among microbic diseases.

5. The prolonged course of chorea and of endo-pericarditis in childhood shows at any rate a persistence of rheumatic infection over a period of months. In the same connexion the case described earlier in this paper may be recalled where a patient was for two years almost continuously disabled by waxing and waning arthritis.

6. Analogy is a much-abused form of support for theories, but it seems legitimate to draw attention to the many infections which are capable, and often convicted, of latency—to name only a few, tuberculosis with its quiescent foci ready to flare up at a favourable opportunity, the extraordinary persistence of bacillus typhosus in bone lesions, of bacillus coli in the liver, gall-bladder, &c., of staphylococci in bone marrow, and so on. If all these organisms can remain latent, reasserting themselves as soon as they get the chance, why should the micrococcus rheumaticus be held to differ from them in this respect?

To summarise, clinical observation of rheumatic infection goes to show (1) a certain similarity of effect, whatever the tissue infected; (2) the capability of such infection to inflict any degree of damage on the tissues attacked, within certain limits (transience and malignancy); and (3) a tendency on the part of the infective agent to persist in the infected tissues.

In conclusion, I must express my thanks to Sir William Broadbent, Dr. Cheadle, Dr. Lees, and Dr. Phillips for permission to quote their cases, and to Dr. Broadbent, pathologist at St. Mary's Hospital, for post-mortem and bacteriological data.

St. Mary's Hospital, W.

RADIOSCOPIC AND RADIOGRAPHIC APPEARANCES IN PLEURISY,

WITH ESPECIAL REFERENCE TO THE UPPER LIMIT OF PLEURAL EFFUSION.

BY J. F. HALLS DALLY, M.A., M.B., B.C. CANTAB., M.R.C.S ENG., L.R.C.P. LOND.,
ASSISTANT RESIDENT MEDICAL OFFICER, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.

Dry pleurisy.—The subject of pleurisy without effusion may be dismissed in a few words. During a period of three months every case which presented the characteristic signs of stabbing pain in the side, dry cough, and friction sounds on auscultation was examined by the radioscopic method, with the result that in only two of these cases was there any loss of clearness corresponding to the part affected. One of these, a case of left-sided pleurisy, was interesting for two reasons. In the first place, with the tube anteriorly a shadow was cast on the right side of the chest with a well-defined margin, concave above, proceeding downwards from the spine of the scapula to the junction of the eighth rib with the vertebral column. In the second place the diaphragm in maximum excursion only moved three quarters of an inch on the affected side, while on the right side it moved one and seven-eighths of an inch. In quiet respiration the movement was five-eighths of an inch on the right side and three-eighths of an inch on the left.[1] The marked limitation of diaphragmatic movement on the left side was due to pain produced on taking a deep breath, the action being thus checked. On further examination the diagnosis of thickened pleura was reached. A history of right-sided pleurisy three weeks previously was obtained, but there were probably previous attacks to account for the thickening. Hence, on the whole, it is reasonable to conclude that acute pleurisy coming on for the first time when in the dry stage casts no shadow.

---

[19] Church: "Acute Rheumatism," Allbutt's System, vol. iii

Pleurisy with effusion.—Appearances vary according to the amount of fluid contained in the pleural cavity at the time of examination. The patient should first be examined in a sitting posture with the tube posteriorly and the screen in front of the chest; then with the tube anteriorly and the screen on the back of the chest; next lying quite flat on his back on a canvas stretcher (or other form of support which will allow of the transmission of the Roentgen rays), under which the tube is placed; and finally, if necessary, the patient can be examined lying on his abdomen or lying first on the right and then on the left side with the tube and screen on opposite sides of the thorax. The most useful skiagram is taken with the tube posteriorly and the plate against the anterior thoracic parietes, as this position shows best any displacement of the heart. The right and left lateral positions are of value in a difficult case in deciding between pleural effusion and a very dense and consolidated lung, for the upper limit of opacity will alter its position unless the effusion be loculated. In one case which was examined with the tube anteriorly, the man being seated, the whole of the lower part of the left side of the thorax was in shadow continuous with that of the diaphragm as far as a line slightly concave above extending in a direction downwards and outwards following closely the direction of the seventh rib. Since here I had not previously percussed or auscultated the chest, the diagnosis on the screen examination alone rested between thickened pleura and serous pleural effusion, the loss of transradiancy not being sufficiently great to obscure the rib outlines. On listening over the area in shadow voice and breath sounds were heard distinctly and the vocal fremitus was not diminished, so that pleural effusion was put out of court. The greatest difficulty in the discrimination of fluid in the chest is met with in children; here, therefore, radioscopy is of the greatest service. The chief points to note in conducting such an examination are:—(1) the height of the fluid on the affected side; (2) the contour of the upper margin of the fluid; (3) whether or not the outlines of the ribs can be distinguished; (4) the position of the heart; and (5) the movement of the diaphragm, if this be visible. In this condition I believe the screen to be of more value than the radiograph on account of the facility with which alteration in position of the pleural effusion on change of posture can be recognised.

The conclusions which I have arrived at by means of radioscopy are these: (1) That the level of the fluid changes with the position of the patient unless (*a*) the quantity of fluid be great and (*b*) the fluid be encysted by adhesions; (2) that a purulent effusion yields a shadow of greater density than a sero-fibrinous effusion; (3) that the shadow is homogeneous and in the case of serous effusion gradually increases in density from above downwards; (4) that, however far the heart be displaced to the right, in most cases little alteration takes place in the position of the apex relatively to the base; (5) that other conditions being equal the heart is displaced more when the effusion is left-sided; and (6) that a somewhat triangular shadow, not normally visible, above and continuous with the shadow of the heart and pericardium is cast by the mediastinum which is displaced by the lateral pressure towards the healthy side of the thorax.

In a communication made to the French Academy of Sciences Professor Bouchard[2] states that on radioscopic examination the translucency at the apex increases as the effusion becomes absorbed. In one case, however, he noted that although the effusion was obviously diminishing the opacity at the apex still remained. "This fact," he says, "caused me to suspect that consolidation had occurred at the apex of the affected lung. Percussion and auscultation confirmed this and revealed the presence of commencing infiltration hitherto masked by the effusion."

Williams writes[3]: "The outline of the diaphragm is less defined, or obliterated altogether, according to the amount of fluid present, as are also some of the ribs in the upper portion of the affected side." The first half of the statement holds good but the latter half seems incomprehensible unless the word "upper" be a misprint for "lower." In every case of pleural effusion the outlines of some of the lower ribs are obscured, and if the effusion be dense enough they are obliterated. I have never seen a case in which the outlines of the upper ribs were obliterated unless the chest were full of fluid, in which case no detail can be made out at all.

In the classical researches of Damoiseau[4] we find the following: "Whenever the absolute dulness rises to the height of a horizontal plane, reaching as far as seven centimetres or thereabouts above the nipple, it is limited by a line which is almost level. Below this plane, on the other hand, it is always outlined by irregularly parabolic curves, less and less open, which form in the latest stage a demi-ellipse." This is stated by Damoiseau to be constant in all cases.

Osler says[5]: "It has long been known that when the patient is in the erect posture the upper line of dulness is not horizontal but is higher behind than it is in front, forming a parabola." In medium-sized effusions the line which marks the intersection of the plane of contact of lung and fluid with the chest wall "begins lowest behind, advances upward and forward in a letter S curve to the axillary region, where it proceeds in a straight decline to the sternum" (Garland quoted by Osler[6]). If the exudation be larger in amount the curve becomes much flatter and almost horizontal. The dulness, although modified to some extent by the condition of the lung, approximately indicates the actual level of the fluid within the pleural cavity. But what do we find on radioscopic examination?

In a paper by Professor Bergonié and M. Carrière[7] careful notes are given of 11 cases of pleurisy with effusion. These I will briefly summarise in order to show coincidence or not of the upper level of the shadow with that of the dulness.

Right Pleural Effusions.

Case.	Upper margin of opacity.	Percussion dulness.
1	Horizontal.	No coincidence.
2	Concave above.	Upper margin of opacity five centimetres below level of percussion dulness.
3	"	Upper margin of opacity just below level of percussion dulness.
4	Concave above after tapping.	No coincidence.
5	Convex above.	Coincidence.

Left Pleural Effusions.

6	Horizontal.	No coincidence.
7	Convex above.	Coincidence.
8	"	"
9	No precise results.	—
10	Concave above.	Coincidence.

Double Pleural Effusions.

11	Right side horizontal; left side concave above.	No results stated.

Hence we see that in four of these the upper limits of percussion dulness and of shadow exactly coincided with each other, in two there was almost exact coincidence, in three there was no coincidence, and in two no results were stated.

In the majority of cases I think that the results on radioscopic examination correspond with those on percussion. Where they differ we have to seek for a cause. The explanation in some cases may be as follows. The lung is liable to become adherent by a portion of its surface to the chest wall. The level of the fluid being represented by a straight line, the lung dipping into it may be represented by a curve with its convexity below. Hence the thin layer of fluid and the air-containing lung, opposite to where the lung dips into the fluid, will be seen radioscopically as a lighter and more transradiant area, convex below, whereas at the sides where only fluid is present and no lung the shadow will be much more dense. Hence adhesions probably account in some cases for the lack of coincidence. In sero-fibrinous effusions the shadow increases from above downwards and thus corresponds to the increasing dulness of the percussion note over the same area.

[6] Ibid., p. 669.

[7] Bergonié and Carrière: Archives d'Electricité Médicale, July 15th, 1896.

Among the deductions drawn by Bergonié and Carrière in the paper referred to above is found the following: "When the upper surface of the liquid presents, both to percussion and to the fluoroscope, the classic curve of Damoiseau we may be sure that the convex part corresponds to a hyperæmic or atelectatic area, for if we make the patient cough violently or take four or five deep inspirations we may see that the surface becomes horizontal instead of convex."[8] This deduction appears to me to be questionable. In the first place, I deny that a hyperæmic lung gives a shadow of the same density as one which is in a state of collapse. A lung in a condition of apneumatosis or acquired atelectasis gives a shadow of corresponding density to one which is the subject of fœtal atelectasis where the lung has never been inflated. A radiograph of a fœtus which has never breathed shows that the lungs exhibit the same loss of transradiancy as the rest of the tissues of the body with the exception of the bones. This condition is unlike that of the hyperæmic lung, in which case it is doubtful whether a shadow be thrown at all (*vide* Hugh Walsham's[9] experiments with washed lungs). The surface of the fluid naturally becomes more horizontal on deep inspiration owing to increase in the intrathoracic pressure; why the convex part should be thought to correspond to a hyperæmic or atelectatic portion of the lung does not seem obvious. Between the upper limit of the effusion and the spine there is often seen a faint shadow somewhat oval in outline. This corresponds to the compressed lung, which appears denser than that on the opposite side, but not completely airless. My own experience coincides with the observations of Walsham[10] and Williams,[11] which show that oftentimes the lung is compressed on the inner side of an effusion with a sickle shaped edge.

Much more work still remains to be done on this subject and the few brief preceding notes do not pretend to be anything in the nature of an exhaustive survey of the subject.

As regards the diagnosis between sero-fibrinous effusions and empyema, by the difference in the density of their shadows, the evidence of various observers is to a certain extent contradictory. With respect to this I will confine myself to facts which I have noted. If a large drop from a serous effusion and another of equal size from a purulent effusion be placed upon a radiographic plate the skiagram will show the shadow of the pus to be the denser of the two. A similar result will be obtained by radiographing two test-tubes, side by side, filled each with an equal amount of serous and purulent effusion respectively—the shadow of the glass being equal in each case; the pus gives a shadow almost as dark as that of bone of equal calibre. This corresponds with what we would expect were we to compare the density of the two fluids, since, volume for volume, the pus contains a much greater proportion of solid material in the form of dead leucocytes and débris than does the serous fluid.

In all cases which I have seen up to the present time serous effusion throws a light shadow usually with a well-defined curved upper margin; a purulent effusion throws a dense or even opaque uniform shadow. In the former case the rib outlines are not obliterated, in the latter they most frequently are. These results have been verified by subsequent tapping. Pleural effusion can be distinguished, unless too great in amount, from thickening of the pleura by the change in the level of the upper margin on movement. Hence, by the aid of the Roentgen rays we are often able to determine whether fluid be present in the chest or not and, if present, from the density of the shadow to arrive at a conclusion as to the nature of the exudate.

Ventnor.

CHOLECYSTOTOMY FOR ACUTE POST ENTERIC INFECTION OF THE BILE CHANNELS; RECOVERY; DEMONSTRATION OF THE PRESENCE OF THE BACILLUS TYPHOSUS.

BY J. LYNN THOMAS, C.B., F.R.C.S. ENG.,
SURGEON TO THE CARDIFF INFIRMARY; CONSULTING SURGEON TO THE HAMADRYAD HOSPITAL, PORTH HOSPITAL, BRIDGEND COTTAGE HOSPITAL, AND CARDIFF PROVIDENT DISPENSARY;

AND

H. A. SCHÖLBERG, M.B. LOND., D.P.H. CANTAB.,
LECTURER IN BACTERIOLOGY, UNIVERSITY COLLEGE, CARDIFF.

ONE of us (J. L. T.) saw a man, aged 40 years, in consultation with Mr. J. Morgan Evans, of Llandrindod Wells, on August 21st, 1903. The history of the illness was briefly as follows. The patient contracted fever whilst in Paris and the first symptoms of the disease showed themselves on the night he left Vienna for Lucerne (June 29th) where he took to his bed on arrival and was laid up for five weeks under Dr. Siegfried Stocker. As soon as he was allowed to travel he hurried off to Llandrindod Wells on account of a former experience of the good effects of the water and climate upon him. The temperature chart he had with him showed the ordinary course of enteric fever. He arrived at Llandrindod Wells on August 15th and three days later he complained of pain and discomfort on the right side of the abdomen. Mr. Morgan Evans was called in on the 16th and found the temperature raised and a diffused tenderness over the ascending colon. These symptoms increased in severity and the tenderness became more definitely localised towards the hepatic flexure of the colon. When the patient was seen in consultation at 10 A.M. on the 21st the symptoms were slight cholæmia, raised temperature, and exquisite tenderness over the right hypochondriac region, with a maximum point over the area of the gall-bladder. On percussion the lower border of the hepatic dulness showed evidence of a probable distension of the gall-bladder which was mapped out on the skin. After consultation the patient refused our advice of having an operation performed but in about six hours he changed his mind owing to the increasing severity of his symptoms and when I (J. L. T.) percussed his abdomen again the dulness had increased an inch downwards and inwards towards the umbilicus, leaving no doubt practically as to the nature of the swelling. The rapid distension of the gall-bladder is worthy of comment, as we found three hours later when the operation was performed that the dulness had again increased at least half an inch during that time. I have never seen such an extraordinarily rapid distension of the gall bladder in other cases of infective cholecystitis, although I have had one case of infection by the streptococcus longus alone and another one which terminated in gangrene of the gall-bladder walls, as well as many other cases of a mixed infection in calculous cholecystitis. Rupture of the gall-bladder would have taken place before long had the operation been delayed.

Operation was performed on August 21st at 6 P.M. Dr. J. Murray anæsthetised the patient with ether after giving a hypodermic injection of strychnine and digitalin to counteract the post-enteric feebleness of the heart's action and Mr. Morgan Evans assisted me at the operation. A little clear fluid was found in the abdominal cavity and the gall-bladder was distended to the size of a hen's egg and projected well below the free edge of the liver. Its walls were very tense, the peritoneal aspect was glistening, and one could see a few white flakes in the clear fluid inside and one white patch could be seen on the mucous membrane near the fundus of the gall-bladder which was probably ulcerative in character and indicative of a threatening perforation. The tension of the gall-bladder wall was relieved by aspiration and afterwards a purse string suture was placed in its walls and a piece of firm indiarubber tubing was inserted through an incision and the purse-string tied round it; a second suture was placed round the gall bladder and the drainage-tube on the proximal side of the purse-string in order to safeguard against leakage through the puncture holes of the needle in introducing the purse string suture. It is always safer to apply the second ligature round a purse-string suture for retaining drainage-tubes in all cases where the walls are very thin and the difficulty of avoiding puncturing the mucous membrane is insurmountable. The same difficulty is found in draining cases of acute distension of the intestine; in this manner with a rubber drainage-tube (as was done and introduced by the late Mr. Greig Smith of Bristol) and a second ligature there is a like benefit in these cases. It is almost impossible not to contaminate the field of operation in cases of acute distension of the gall bladder unless the tension is greatly reduced before the introduction of the purse-string suture; as soon as one can get a fold of the walls between the fingers then the cause of one's greatest anxiety is over. When circumstances allow I always push into the portion of rubber drain which is inserted into the gall- [illegible] easons that that [illegible] collapsable and [illegible] more especially on account of the fact that one can tighten quickly and forcibly the purse string suture without any fear or danger of causing kinking or occlusion of the rubber drainage-tube. The character of the fluid removed from the gall-bladder is worthy of remark in connexion with the probable route of infection of the gall-bladder. The fluid from the fundus was practically transparent and limpid, but the last portion which came from the deepest part in the vicinity of, and perhaps from, the cystic duct was milky and was immediately followed by bile-coloured fluid with a peculiar weak nauseating smell.

After the operation the patient passed a very good night and all his pain and tenderness immediately left him. Six days later the drainage-tube was removed and two small calculi of recent origin were removed from the cystic duct [illegible] pious at first [illegible] umbilicated [illegible] a distance of three inches. The non pustular area was dressed with iodoform gauze, whilst the pustular area was at the junction of the double cyanide dressing with the iodoform gauze. By altering the dressings and by the application of topical treatment to each pustule the further treatment of the case was satisfactory. A week after the operation all traces of jaundice had disappeared and Dr. Cobleigh of Kingston, Pennsylvania, U S A., who had previously known the patient, stated that his eyes were clearer than they had been for nearly two years as the patient normally was of a "livery" disposition.

Cases of post-enteric infection of the gall-bladder which come under the hands of the surgeon are comparatively few as the treatment and the recognition of such cases are of quite recent date. The routes of infection are three: (1) the blood, when we must assume a *locus resistentiæ minoris* of the infected part; (2) transperitoneal; and (3) direct continuity by advance from the duodenum. The character of the fluid in this particular case showed more advanced changes in the portion coming from the cystic duct and would probably point to infection by direct continuity.

From post mortem records of cases of typhoid fever the occurrence of a specific infection of the gall-bladder is seen to be fairly common, and this fact, coupled with the records that exist of the isolation of the typhoid bacillus from the blood, urine, and sputum during life, shows that there is a definite systemic infection in a certain number of cases of typhoid fever. The bile, and therefore the bile in the gall-bladder, may be expected to show a similar infection. James Stewart,[1] in an interesting report on 620 cases of typhoid fever from the Royal Victoria Hospital, Montreal, stated that in his experience the complication of cholecystitis occurred but seven times and all recovered except one. Of the seven cases three were operated on and all had calculi and yielded the typhoid bacillus in pure culture. All these were cases occurring during the disease, but they can hardly be the only ones in which infection of the gall-bladder took place. In fact, a post-typhoidal cholecystitis has been recorded seven,[2] 15,[3] and 17[4] years after the original attack of fever, showing that the typhoid bacillus may be latent for a considerable time without giving rise to local symptoms. How far the presence of gall-stones before a specific infection, or as a result of such infection, determines the onset of an acute cholecystitis it is not easy to say, though the majority of cases operated on for post-typhoidal cholecystitis contain calculi in the gall-bladder. The probability is that the incidence of cholecystitis during or after an attack of typhoid fever will depend on purely local conditions and such will determine the time of onset. In our case the onset was just after convalescence. The infection was not a pure infection, the bacillus typhosus and the bacillus coli communis being both present. The typhoid strain isolated fulfilled all the cultural characteristics of the specific organism, as well as in its morphology (flagella). The blood serum of the patient agglutinated the organism to the same degree as it agglutinated the laboratory stock culture of typhoid bacillus and the organism behaved in the same manner towards the blood serum of other cases of typhoid fever. The bacillus coli was also typical in all respects.

In conclusion, I (J. L. T.) may be allowed to express my admiration at the prompt manner in which a room was converted into a model operation theatre by covering carpets and everything with sterilised white bed-sheets, at the careful way the ether was given by Dr. Murray, and, lastly, the plucky manner in which Mr Morgan Evans threw the entire responsibility of further delay upon the patient and his friends.

SOME IMPRESSIONS OF SALSOMAGGIORE AND ITS BATHS.

By W. W. BALDWIN, M.D.

SALSOMAGGIORE is an old acquaintance among the spas of Italy. My first visit there was made in the summer of 1884 in behalf of certain patients. It was no Lombard paradise in those days. One drove nine miles from San Donnino in billowy clouds of grey dust to be set down at last in a rather squalid, dilapidated village, swarming with flies and fleas and haunted, like Constantinople, by mongrel dogs. The few hotels were fairly good and comfortable, although primitive and simple. The country side was charming and the drives were most beautifully picturesque, although the dust still persistently surrounded one upon every movement. No doubt the country wine, which was liberally supplied without extra charge at meals, owed something of its acrid, gritty quality to the all-pervading surface powder, ground by traffic out of the smooth, hard, well-kept roads. This wine was the most active diuretic my professional experience has ever encountered, a quality that doubtless explains the avidity with which the male population seemed eagerly to haunt the convenient open places provided as urinals upon every corner. Northern visitors were much annoyed at first, to say the least, by this novel feature of Italian towns. But by-and by they ignored, as far as possible, what was unwelcome by observing more and more attentively things of artistic beauty and charm which fill the eye and stimulate the imagination upon every hand in adorable old Italy.

Notwithstanding these rather serious drawbacks to holiday humour a certain delightful hospitality and cordial coöperation to assist my purpose of study shown me by the Italian physicians then in charge of the baths make my memory of that ten days' visit a very pleasant one. I was also impressed by the dignified simplicity of our Italian *confrères* and the serious thoroughness which they displayed in their work. This also contributed to render my visit profitable as well as delightful.

From this time during active professional life in Florence until 1898, when I went to Rome, I continued to send patients to Salsomaggiore with growing confidence and satisfaction. I found that not only brilliant curative results were generally obtained in appropriate cases but that a certain proportion of these patients were permanently cured. It was also clearly noted that failures were more frequently due to mistakes in judgment as to indications than to any lack of therapeutic power in the treatment itself. In general experience taught me that acute inflammations were almost invariably aggravated by these baths and applications, but subacute inflammatory conditions and post-inflammatory adhesions and deposits were usually benefited or removed whatever the exciting cause. Thus the objection that these waters are prescribed for too great a variety of diseases may be met with the statement that their curative scope and value lie chiefly in the treatment of the results of inflammation following so many diseases or diseased conditions

In my practice one rarely meets with those tuberculous and tertiary specific lesions such as suppurating glands, open joint and bone abscesses, gummata, &c. These dreadful scourges of the ill nourished poor from damp, sunless, insanitary dwellings will require a separate discussion, and upon another occasion I purpose to publish an account of several hundred cases of this kind that came for treatment to my summer clinic in the Apennines in the summers of 1893 and 1895. Some of the worst of these cases were sent to Salsomaggiore for treatment by the village and town communes, assisted by generous private charity. It is worth remarking that some of the cures were extraordinarily brilliant and successful and many of those poor patients were restored to useful work-a-day life.

The only method of inhalation employed at Salsomaggiore during this time was the direct spray which was, however, so efficacious in chronic catarrhal and other affections of the upper air passages that I have continued to prescribe the "acqua madre"[1] of various strengths in private practice ever since with great success. This water, bottled and numbered according to strength, can be purchased at any pharmacy in Italy, and elsewhere if ordered, and by means of a suitable steam atomiser it may be inhaled at home with almost as much benefit, I believe, as at headquarters. I am also convinced that this procedure as claimed at Salsomaggiore does, in large measure, prevent the more or less frequent acute catarrhal attacks some months after the treatment.

Upon reviewing my notes from 1883 to 1898, during active professional work in Florence, I find three classes of cases recorded as having been treated at Salsomaggiore: (1) chronic arthritis of gouty, rheumatic, or gonorrhœal origin, muscular rheumatism, and rheumatoid arthritis; (2) various gynæcological ailments in chronic stage, such as endometritis, parametritis, and perimetritis, pelvic peritonitis, pelvic cellulitis, &c., certain cases of salpingitis, ovaritis, &c., functional derangements such as amenorrhœa, menorrhagia, dysmenorrhœa, suppressed or irregular menstruation due to various conditions of general debility or retarded development, and several cases of uterine myo-fibroma, accompanied by more or less menorrhagia; and (3) various chronic affections of the upper air passages such as naso-pharyngeal catarrh, bronchial catarrh of the larger tubes, &c.

In the first class I remarked, in almost every case, not only satisfactory improvement in the local condition but also great gain in the general health. Some patients who had been more or less crippled were restored to greater activity and others, by means of supplementary treatment with massage, electricity, &c., during the colder months at home, were relieved of former disabilities and gradually cured. I noted, however, that results in muscular rheumatism and rheumatoid arthritis were not generally so favourable and was led to adopt other treatment for some of these cases. In the second class of cases some very remarkable cures were noted and in general it might be said that not only was the proportion of permanent cures far greater than by any other treatment but relief was obtained in almost every case. Several cases of sterility were cured, one of which is sufficiently instructive to be reported.

A strong, well-developed, healthy young woman who during the first year of married life had a miscarriage due to accident, suffered over seven years previously from endometritis, dysmenorrhœa, profuse leucorrhœa, and general ill-health. For maternal and family reasons she was most anxious to have a child. She had undergone various kinds of treatment, including several operations such as curettage, mechanical dilatation, &c. She went to Salsomaggiore in the summer of 1890 by my advice, where the treatment consisted of baths and irrigations with "acqua madre." She returned to Florence much improved in every way. During the following winter she continued the douches with "acqua madre" and went to Salsomaggiore again the following summer. After the second course it was noted that not only was the local trouble comparatively well but that her general health was excellent. In the winter of 1891–92 she became pregnant and in due time, after an easy labour, gave birth to a healthy male child. Since then she has had two other children and remains in excellent health.

Treatment of the third class of cases by means of inhalations (and baths where there was a gouty or rheumatic background) was also signally successful. Indeed, I was led by-and-by, as experience grew, confidently to expect a larger proportion of cures in these cases at Salsomaggiore than by any other method I have ever known. Regarding my few cases of uterine myo-fibroma treated at Salsomaggiore, I did not record very definite results and do not consider my limited experience as warranting any conclusions.

Upon this basis of assured and approved therapeutic value an enterprising commercial company invested a large capital in truly admirable improvements, which were begun in 1899 and rapidly pushed towards completion, at the same time advertising the place so extensively in the Old and New World that Salsomaggiore and its wonderful curative properties have been ever since a topic of the time. As a result it has had a great American boom and a large contingent of foreign patients have been attracted to this modern Pool of Bethesda. It must be confessed, however, that, as is usual in such circumstances of artificially stimulated interest and excitement, the spa has been magnified into a universal panacea for every earthly ill and many unsuitable cases have gone in the vain hope to be healed. But the scientific conscience and accuracy have latterly evolved order out of the inevitable early confusion of such an extensive undertaking and at present greater care is exercised to avoid mistakes and to select only such patients as are susceptible of cure by this treatment.

Wholesale exploitation of human misery and credulity still remains a monopoly of the various money-making delusions. This fever of expectation upon every hand has interfered with the ordinary prosperous pursuit of healing and rendered it necessary to lay down the law most decidedly to some patients regarding the indications and limitations of treatment at Salsomaggiore. Indeed, one of the trials of a physician's life lies in the almost invincible difficulty of teaching primitive ideas of hygiene and of inducing obedience to simple natural laws. Certain patients are eager consumers of drugs and they throng the various spas in lively expectation not only that results of past social dissipation will be cured but that they may also thus obtain assurance for future license. As apostles of the truth we can only preach of nature's certain and remorseless revenge for all such self-indulgence and clearly show that no medical treatment, however skilful, can ever take the place of "physical righteousness."

Owing to important consultations I had been unable to visit Salsomaggiore since its renaissance until October, 1902, and again in August, 1903, to inspect the widely-heralded improvements. I was also anxious to investigate the claim that this treatment should be extended to a much wider range of diseases and diseased conditions than had been formerly contemplated and to obtain at headquarters in present circumstances more exact knowledge regarding indications and contra-indications to the treatment than had hitherto been published. Certain untoward accidents had also occurred in cases ill suited to those powerful baths or where the treatment had probably been pushed too rapidly. At the same time it seemed a favourable opportunity to discuss the wisdom of giving so much shorter courses of treatment here and in the other watering places of Italy than is the universal rule in the older northern spas of Germany, France, and elsewhere. For the purpose of making these and other inquiries I interviewed the various Italian specialists in charge of the baths. It is very pleasant to record again the charming courtesy and delightful kindness of our Italian colleagues; not only were all doors opened wide at my request but unwearied pains were taken at all times and seasons to demonstrate, to instruct, and to explain every detail connected with thorough and painstaking work. My questions were answered so fully and cheerfully that one seemed to be conferring rather than receiving favours. I was assured that great precaution had been taken to prevent accidents in future and to insure general safety in all respects. But of this later. The changes since my first visit were amazing; not only had the old hotels been rebuilt and regenerated as regards comfort and sanitation, but I found a large modern hotel upon a commanding site. This hotel is one of the best of its kind in any spa. Its situation at the junction of two valleys gives it free ventilation and for this reason the nights were fresh and cool in spite of the heat which prevails in Lombardy during the months of July and August. This hotel has provided baths upon every floor for patients who are unable to leave the house There were two new baths, one of which, the Magnaghi, is a model of its kind, furnished with every modern balneological equipment, including a complete medical electrical installation The village, although still leaving something to be desired by way of cleanliness, was undergoing the same transformation as the baths and hotels Many of the objectionable open convenient places had been replaced by decent covered iron structures (the same may be said of all the large towns in Italy) The fleas and flies were less numerous and the dogs had almost disappeared The dust was laid by frequent street sprinkling and although there were much débris and confusion here and there incident to rapid growth in building one could imagine a near future when this watering place will become one of the best and most complete of its kind So much in commendation of the work already accomplished and still in process of completion

---

[1] Literally "mother water," the concentrated liquor that remains after evaporation of the iodo bromo saline water to remove common salt.

For particulars of the chemical analysis of the waters, description of the baths, &c, as well as the original discovery of the presence of organic iodine and sulphur compounds in the inhalation rooms and other important observations, I must refer to the admirable and exhaustive report of THE LANCET Special Analytical and Sanitary Commission on the Iodo-bromo Saline Waters of Salsomaggiore[1]

It is obviously of the greatest importance not only that physicians should have expert knowledge of balneology in general but also that they should have clear and definite ideas regarding indications and contra indications to treatment in those most potent available baths of their kind in the world Just in proportion to the undoubted efficacy of this treatment in appropriate cases must its power for harm and even disaster be when it is rashly or injudiciously adm [illegible] re some contra indications to the [illegible]

1 [illegible] it but a meagre pittance of reserve vital force to draw upon in case of emergency should not take the full baths

2 Where the excessive metabolism induced would throw a dangerous or even fatal burden of overwork upon organically diseased excretory organs, as in Bright's disease

3 In advanced arterial fibrosis or atheroma, especially if asymmetrical, these baths might initiate more rapid degenerative changes and even produce fatal accidents by causing excessive vaso dilatation on the one hand and through reflex action slower more powerful cardiac contraction on the other Thus the more inelastic vessels would bear the brunt of impact and either give way, as in apoplexy, or be strained and damaged, anticipating the slower advance of senile degenerative changes by many years as has occurred in several cases Dr Zoia claims that degenerative diseases of the aorta and carotids of syphilitic origin derive much benefit from these baths except when there is constant high arterial tension He never prescribes them, however, in such cases at a higher temperature than from 33° to 34° C

4 In any case where, owing to vital depression from any cause, reparative processes cannot keep pace with the tissue waste induced by this treatment

5 In advanced organic heart disease, almost without exception, these baths are too powerful—at least, they should not be prescribed in such cases until more accurate and exhaustive studies have been made regarding their effects upon blood pressure, &c I do not believe, however, that they can ever replace the Schott-Nauheim treatment for chronic heart diseases. While well compensated valvular cardiac lesions without degenerative changes in the myocardium might not contra indicate the treatment when necessary for other conditions nevertheless, in these circumstances, the temperature of the baths should never exceed 34° C

6 Certain patients with irritable skins cannot take these baths without suffering from dermatitis, eczema, &c In a certain proportion of these cases Professor Baistrocchi has called attention to the fact that "acqua madre" baths, diluted with sterilised sweet water, are not only well borne but that they frequently act most favourably upon such conditions of the skin

7 Patients who have tuberculosis of the lungs and intestines are not allowed to take the treatment at Salsomaggiore on account of the danger of importing infection It has been proposed to treat this class of cases at some distance where the waters are analogous although not as strong

8 When the baths cause debility, insomnia, and nervous irritability which do not improve under the milder, slower course of treatment, or by substituting the more sedative baths of diluted "acqua madre" (Baistrocchi), the treatment should be interrupted or suspended I believe that a continuance of these symptoms forbids the treatment, certainly at the time, and I do not believe that any future good can be predicted which would warrant such lowering of present vital force, notwithstanding traditions to the contrary in various watering places

9 Acute inflammatory conditions, such as gout, rheumatism, parametritis and perimetritis, &c, would certainly forbid these baths I am aware that there are occasional exceptions to this rule, but who can distinguish them in given cases? These exceptions therefore must be regarded as fortunate accidents rather than encouragement to rashness Acute rheumatic and gouty attacks in joints, if inevitable, are most satisfactorily located for rational and successful treatment, but formidable explosions in the brain, heart and other vital organs have been caused by attempts to abort these diseases by means of powerful saline baths There is good reason for the popular belief in "the great danger of driving these diseases in"

10 Latterly cases of nervous prostration, neurasthenia, hysteria, and other nervous maladies, with or without anæmia, have been treated at Salsomaggiore with more or less success But we have not been instructed at headquarters as to what class of these cases are appropriate for treatment Surely we have more rational and hopeful methods of treating the various nervous disorders, resulting from our terrific modern life, with its inhuman discord, intolerable tension, worry, and dissipation of vital force, than by those incalculably searching iodo bromo saline waters Where these conditions, however, follow the various specific inflammatory disorders, by removing the cause we may hope to cure the symptoms as well "Cases of cerebral exhaustion following overwork in gouty or rheumatic subjects have been rapidly benefited by these baths, when the temperature does not exceed 33° or 34° C Hot baths in these cases cause insomnia and cool baths relieve it" (Zoia)

11 Primary anæmia and chloro anæmia are, I believe, more successfully treated at ferruginous springs, such as Schwalbach, Spa, &c, or by the arsenical iron waters of Levico, Roncegno, Bourboulle, &c, but where the anæmia has been caused by certain of the inflammatory conditions mentioned Salsomaggiore by curing the one frequently removes the other Where anæmia is a complicating factor and not the result, or when it is more profound than usual, a so-called after cure is indicated at one of the iron or arsenical iron springs In some cases the tonic treatment should precede the iodo bromo saline baths In cases adapted to this treatment, however, the accompanying anæmia is usually much benefited, the hæmoglobin and red blood corpuscles increasing very rapidly There are certain unfortunate victims of hereditary tuberculous or syphilitic taint who are never very well and strong They suffer from anæmia, swollen glands, various eye troubles, chronic naso-pharyngeal and bronchial catarrh, &c. They have dry inelastic skins, defective teeth, and having passed the storms and perils of infancy and childhood often show unmistakeable signs of former rachitis. They have small power of resistance and fall easy prey to acute infectious diseases from which convalescence is prolonged They may have escaped definite attacks of the family disease because they have been better housed, better fed, and better clothed than their poorer neighbours, and have always been under skilful medical supervision For this class of patients the treatment at Salsomaggiore is very successful, not only for the subacute and chronic stages of intercurrent maladies, but also for the constitutional vice of defective blood and tissue building

12 Persistent high arterial tension, due to autotoxæmia, would demand great caution in the employment of these baths Should they continue to lower the tension after cautious trial the treatment might be beneficial, but where the tension is not influenced or even raised the treatment should be discontinued at once and other measures taken to relieve this dangerous condition Of course, when the [illegible] at the treatment should never ki [illegible]

be [illegible] eks.

This statement is published in official announcements, as well as in various special papers devoted to the discussion of Salsomaggiore and its treatment. Not only is this course *far too* short to obtain full benefit but experience, even in the milder baths, has taught that only harm can result from pushing the treatment too rapidly. It is the almost universal rule in the older northern spas, where the science of modern balneology has been gradually evolved from centuries of experience and study, that in the beginning of a course of baths it is rarely prudent to give them oftener than every other day. After careful study of the peculiarities and idiosyncrasies of a particular case, observing the behaviour of the excretory organs and blood as well as the nervous system (through frequent chemical analysis, &c.), two and even three baths are given upon succeeding days but rarely more without a day's pause between. The duration of the first bath is rarely longer than from seven to ten minutes at a temperature of 35° C. The strength of the bath solution is slowly and carefully augmented and the duration increased one minute every or every other bath. Except in the Schott Nauheim baths, which are gradually cooled for a specific purpose, the bath temperature is gradually raised ½° to 2° C. every or every other bath according to the behaviour of the blood pressure which is carefully measured. Thus a course of 21 baths would last 30 or more days, but never 21 days as is advertised at Salsomaggiore.

---

[1] THE LANCET, July 12th, 1902 p 84.

I have had occasion to study the bath cards of various patients who have consulted me after their course of treatment at Salsomaggiore and to my amazement have found in certain cases that from 21 to 30 baths had been given in as many days. One patient had taken 25 baths in 26 days. His daily programme was massage, local application of the hot fango (mud) bath, and inhalation. The duration of the first bath was 20 minutes at a temperature of 35° C., and that of the last bath was 35 minutes at a temperature of 39° C. He had been very much pulled down by this treatment but he was assured that great benefit would ensue later. The promised general improvement, however, was very slow to appear and the local trouble for which he took the treatment was not relieved. Another patient took 17 baths and inhalations in 18 days. He undertook the treatment for so-called gouty pains of a vague and fugitive character. He had arterial fibrosis with a rather constant high blood pressure (140 to 160 millimetres of mercury). "The kidneys were not markedly diseased, although they had latterly lagged in their excretory functions." As might have been expected, this patient has not been as well since his treatment at Salsomaggiore, although he had previously been in fairly good health. Degenerative changes in the arteries had been accelerated and the kidneys gave grave cause for anxiety.

These cases will suffice to emphasise my contention regarding this matter. I am happy to say that not only were these and other criticisms favourably received by my Italian *confrères*, but measures had already been taken towards reform as regards northern patients. Italian invalids unfortunately lack the patience and pertinacity to undergo slower, longer courses of treatment. This is undoubtedly the cause of such an anomalous state of affairs in Italy. I was informed upon all sides that those patients who had taken the slower, milder courses of treatment were not only better satisfied with results but were more certain to return for another course.

Professor Baistrocchi, director of the sanatorium at Salsomaggiore, has introduced admirable sanitary reforms into the various establishments which have been in operation several years—viz., (*a*) disinfection of the bath tubs after each bath by means of creoline solution and corrosive sublimate when necessary; (*b*) careful disinfection of the walls, floors, and furniture by means of corrosive sublimate spray; (*c*) most careful disinfection of all apparatus used in the baths and inhalation rooms by means of corrosive sublimate and dry heat; (*d*) spittoons filled with solution of corrosive sublimate for patients and attendants; (*e*) convenient receptacles containing corrosive sublimate for disinfecting the hands, &c.; (*f*) various apparatus for sterilising all sweet water and "acqua madre" employed in the baths and all solution used for inhalation, as well as the mud for local applications and the various receptacles; (*g*) a thorough system of ventilation for bathrooms, inhalation rooms, &c.; and (*h*) most admirable methods of cleaning, disinfecting, and sterilising all linen used in the establishments, including separate protected rooms for handling soiled and surgically clean linen as well as separate receptacles for conveying the same to and fro. The rooms where the clean sterilised linen is washed and stored are most carefully disinfected and the servants employed for the work are required to observe such precautions as disinfection of the hands, clothing, &c. During more than 20 years' study of balneology at various watering places in Europe and America I have never seen such sweeping and radical sanitary measures employed elsewhere. But servants are not infallible and it seems not unreasonable to suggest in order to render this excellent system more perfect that all patients with open tuberculous lesions and all syphilitic cases whatsoever should have separate sections not only to protect those having the same disease from infection by the other but also to avoid any possible danger to the other patients. This imperative precaution has been recently adopted at the Magnaghi and doubtless will be introduced into the other establishments during the coming season. Not only is the drainage of the various hotels and establishments equal to modern sanitary requirements but frequent flushing of the waste pipes with the bath water, which is a disinfectant, provides an additional safeguard against infection.

In answer to my criticism that strict rules regarding rest after the baths and applications had not been generally enforced in Salsomaggiore, Dr. Zoia informed me that he always insisted upon an hour's rest in bed immediately after each bath, and he hoped that this wise measure would be made obligatory. He also informed me that private rooms had recently been provided for the purpose at the Magnaghi establishment. Professor Baistrocchi has also published rules regarding rest after the treatment, particularly after the inhalations. The Italian Government with wise liberality permits all physicians with unexceptionable qualifications, of whatever nationality, to practise in Italy. No doubt the great army of strangers who come every year to visit her monuments of history and works of art, contributing a vast annual income to promote general prosperity, is the direct cause of this enlightened policy. In Salsomaggiore, however, certain restrictions have been introduced upon Professor Baistrocchi's initiative—viz., the so called "Tessera" or official permission to take treatment. As this measure has caused much discussion and some heart-burning it merits a word of explanation. Only the physicians who compose the medical council have the right to issue the "Tessera" to their own and other patients after careful examination. Considering the very powerful character of the baths and the disasters that might occur through mistakes in prescribing the same, this supervision is prudent and justifiable. Of course such powers should be exercised only by well-qualified specialists with judicious impartiality. I have no doubt, however, that the matter will be satisfactorily adjusted. In view of the great value of massage and Swedish gymnastics as adjuncts to the treatment it is to be hoped that the same liberality will be extended in future towards these trained attendants as in other directions.

It must be said, in simple justice, notwithstanding the fact that these establishments have not yet paid dividends upon the large capital invested, and cannot do so at best for a long time to come, the directors have displayed liberality in promptly carrying out the numerous expensive improvements suggested by the medical council, including an abundant supply of pure and wholesome mountain water for establishments, hotels, and the town. When there is no longer room for criticism in human undertakings the millennium will have dawned. Until then our aim must ever be towards perfection. A writer makes the rather hazardous assertion that no particular regulation of the diet is necessary for those who take the treatment at Salsomaggiore. Professor Riva, however, in his illuminating paper on Subacute and Chronic Arthritis and the Waters of Salsomaggiore, emphasises the paramount importance of rigorously supervising the diet of patients taking the treatment. This he calls "dieto terapeutica," and in conclusion says: "It is so because it is so, and any cure conducted according to the demands of modern medicine cannot and dare not neglect the diet, which must always be regulated in the most careful and scientific manner. Professor Baistrocchi is equally imperative as to the necessity for carefully regulating the diet according to the requirements of each particular class of disease. He has also published a series of diet tables for patients at the sanatorium. The importance of diet in health and disease has been known since the dawn of history and doubtless was practically recognised by mankind before they invented oral and written language. Even the lower animals have wholesome instincts regarding the quality and quantity of food suitable to their condition.

I cannot refrain from expressing my appreciation of the admirable sanatorium and the excellent scientific work accomplished by Professor Baistrocchi and his well-trained assistants. The same thorough disinfection, ventilation, and cleanliness are observed here as in the bath establishments. The "luoghi commodi" (convenient places) have been constructed outside the main building but communicate with it by means of well-ventilated covered passages. These closets are furnished with every modern sanitary safeguard. The food is simple but of the best quality and is furnished even to the poorer patients in great abundance. The soup, which I tried upon Professor Baistrocchi's recommendation, was most savoury and nutritious. The curative results accomplished in the sanatorium, chiefly in scrofulous and gynæcological maladies have been so brilliant that they merit more careful study and discussion. These [illegible] treatment by massage, c[illegible] when necessary.

Pati[illegible] therefore of curative results, passionately desiring to be healed of their infirmities, with as much amusement as may be during the process. They never rise above empiricism and only glorify results, which is natural and commendable. But we must solve, if possible, the difficult problem of the *modus operandi* of these complex remedies upon infinitely more complicated organisms. In no other way can we hope to prescribe them with absolute confidence in all cases and in all circumstances. Upon the threshold of this investigation we must acknowledge that chemistry has hitherto failed to give us a complete explanation of the favourable effect of these waters. Brine baths, in conjunction with various douches, electricity, massage, applications of hot mud, &c., produce analogous but far less powerfully curative local effects than the Salsomaggiore waters employed in the same way. The cause of this more powerful and speedy action was supposed to be due to the absorption of the salts of lithia, bromine, strontium, and especially iodine (and perhaps certain organic sulphur compounds), contained so largely in the latter waters. The most careful tests, however, have hitherto failed to follow these substances from the unbroken skin through the organism, no traces of the same having been discovered in the excretions after Salsomaggiore baths of various strengths, duration, and temperatures. It has been asserted that cataphoresis would explain the supposed absorption. Elevey says that the effect of contact in mineral water baths reinforced by the natural electrical currents is more than sufficient to explain the increased tissue metamorphosis which occurs. At any rate we know that these waters, as employed at Salsomaggiore, do greatly accelerate tissue metamorphosis and that by means of various inhalations the more soluble salts are absorbed through the mucous membrane, thus contributing to enhance curative results.

Almost all varieties of inflammatory adhesions and deposits are liquefied and absorbed; ulcers, bone abscesses, suppurating glands, lupus vulgaris, and other tuberculous lesions are healed; chronic naso pharyngeal and tracheo-bronchial catarrh, and even ozæna, are greatly benefited and often cured; and various secondary and tertiary syphilitic local lesions are much relieved and frequently removed. The various dyscrasiæ accompanying these maladies are rapidly and surely corrected and the organism is placed in more prosperous relation with its environment. Certain amusements are provided at the spa in the way of music and song, light operas, and theatrical representations which help to pass the time more agreeably, although they cannot rival the beauty and charm of this interesting folk and their wonderful country.

In this picturesque section of Lombardy, with its splendid seasonable climate and radiant azure sky, every footstep discovers some trace of Roman baths or other evidence of the extraordinary intelligence and energy of that mighty classic race. Mediæval art has also left enchanting monuments upon every hand—great castles and lordly villas, here and there vast convents and monasteries crowning noble heights, and over all the indescribable atmosphere of brave old Italy, the Madonna country of the world.

A CENTENARIAN.—The Hon. David Wark, of Fredericton, New Brunswick, celebrated his 100th birthday on Feb. 19th and received the cabled congratulations of King Edward on the occasion. He is the oldest public man in the British Empire and possibly in the world. Mr. Wark was born in Londonderry, Ireland, in 1804. He went to Canada in 18?5 entered the New Brunswick Legislature in 1837, and has been a Senator of the Dominion continuously since the Confederation.

A CASE OF GANGRENE OF THE RIGHT FOOT OCCURRING IN THE NEWLY BORN.

BY DIGBY COTES-PREEDY, M.A. CANTAB., L.S.A. LOND.,
LATE HOUSE PHYSICIAN AT ST. GEORGE'S HOSPITAL.

ON August 27th, 1903, a married woman, aged 44 years, was confined of a full-term female child. She was the mother of ten children who are all alive and also had had three miscarriages. At every confinement she had suffered from rather severe post-partum hæmorrhage but otherwise she generally enjoyed good health. In June, 1903, she had a fall from an omnibus step on to her right side and a fortnight later she fell down some stairs in her house, again alighting on her right side. The confinement was superintended by an experienced midwifery student from St George's Hospital. The presentation was of the right occipito-anterior variety. Strong pains commenced at 9 A.M., the child being born at 7.10 P.M. Some difficulty was met with on account of a slight impaction of the shoulders. The umbilical cord was found to be twisted twice round the neck. The right foot was the last to be born, but there was no trace of amniotic bands around it. Owing to the deep cyanosis of the child artificial respiration was resorted to for the space of ten minutes; this restored the breathing but at no time was respiration forcible in character. The general state of the infant continuing unsatisfactory and the condition of the right foot, which is described hereafter, being such that hospital treatment was indicated, a relative was requested to take the child to the hospital for admission, but on arrival at 10.30 P.M. I found that the infant had apparently been dead for about ten minutes.

The post-mortem examination was made 38 hours after death by Dr. T. R. Whipham, to whom I am indebted for the use of the following notes. The body was fat, well developed, and of rather large size. The skin of the lower half of the right leg in front, of the dorsum of the foot, of the dorsal aspect of the first toe, of part of the dorsal aspects of the second, fourth, and fifth toes, and of the inner half of the under surface of the foot, including that of the great toe, was intensely red and devoid of its epidermal structures, being, in fact, in a state of early gangrene. On the dorsum of the foot the area corresponding to the cutaneous distribution of the anterior tibial nerve was specially affected. The gangrene, which was moist, affected only the skin and subcutaneous structures, the deeper parts being healthy; its line of demarcation was sharply defined. No macroscopic cause for the condition was found; there were no pressure on the arteries or nerves, no blocking of the vessels of the limb from the aorta to the foot, and no change to the naked eye in either the anterior or posterior tibial nerves. Microscopically, the posterior tibial nerve was normal. A portion of what was removed as the anterior tibial nerve proved to be the artery. This also was normal. The outline of the gangrene was so irregular that it seemed hardly likely to have been caused by intra-uterine pressure. The umbilical cord was attached and healthy. There were neither external signs of injury nor fractures of the bones. There was no fracture of the cranium. At the base of the brain on the left side there was considerable hæmorrhage under the dura mater but the source of the bleeding could not be determined. The brain weighed 12 ounces. All the vessels on the surface and in the substance were congested but nothing else abnormal was found. The lungs *in situ* were not fully expanded. The edges of both were very emphysematous and in places there was partial atelectasis, small pieces cut from both only just floating in water. The right side of the heart was slightly dilated, otherwise the viscus was normal. The other organs of the body showed no abnormality.

This case I have deemed of interest owing to its rarity. A search through many works has elicited nothing to explain adequately the cause of the gangrene—even Ballantyne's Ante Natal Pathology afforded no assistance. Several theories have suggested themselves, such as amniotic bands, pressure effects produced in utero, the action of bacteria, and, lastly, the increased blood pressure produced by the excessive contraction of the womb during the labour which the minute blood-vessels were unable to cope with—this reason I gave to the deputy coroner (Mr. R. Henslowe Wellington, M.R.C.S. Eng.) in order to account for the subdural hæmorrhage—but they cannot be substantiated sufficiently by the facts at my disposal. The two accidents experienced by the mother prior to the birth of the child seem to offer the only clue to the explanation of a condition which on account of its rare occurrence deserves to be recorded.

I have to acknowledge the kind permission of Dr. A. F. Stabb to publish this case.

Croydon.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF (?) TUBERCULOUS MENINGITIS.

BY WILLIAM R. BATES, L.R.C.P., L.R.C.S. IREL.

THE following case is, I think, of sufficient clinical interest to be recorded. The patient, who was a female, aged 19 years, was first seen by me at my house on Dec. 4th, 1900. She complained of feeling weak and tired, her appetite was capricious, there had been a gradual loss of flesh all the summer with increasing debility, and she had a large, painful, lymphatic swelling on the right side of the neck. Her temperature, taken in the mouth, was normal, her heart sounds were healthy, and there were no abnormal physical signs in the chest or the abdomen. She was ordered to paint the neck with a combination of collodion and belladonna and a pill containing arsenate of iron, nux vomica, and reduced iron was given.

I was called in to see her on Dec. 13th. She had been in bed from the 9th; intense headache commenced on the 10th but she had tried to get up on the 12th and was obliged to return to bed at once; vomiting commenced about 11 A.M. on that day. When seen by me her temperature was 103° F. and her pulse rate was 72; her respirations were quick; she had intense headache and intolerance of light with frequent vomiting; the pupils were equal and dilated; the bowels were constipated; there was no retraction of the abdomen. Her mistress was told that the illness was most probably meningitis and the girl was removed to her own home which, fortunately, was not far distant, where she could be well nursed. A powder containing ten grains of phenacetin and six grains of mercurous chloride was given. On the 14th she was worse. There was constant meningeal cry with marked retraction of the head; the vomiting still continued and occasional delirium was noticed. The patient's head was shaved, a large blister was applied to the nape of the neck, iodide of potassium in ten-grain doses with 15 grains of bromide of potassium was given every four hours, and mercurial ointment was rubbed into the axillæ and the groins night and morning. Her temperature ranged between 101° and 103° and the pulse was markedly slower. On the 15th the patient's condition was much the same but the pupils were sluggish in acting; her temperature was about the same and her pulse rate was 56; sobbing respiration was also noticed. On the 16th there was paralysis of the external rectus of the right eye. The discs were examined and marked neuritis was found but *no* tubercle was seen in the choroid. Vomiting still continued but was not so incessant. Tache cérébrale was well marked. On the 17th she was seen by me in consultation with my friend Dr. J. N. Richardson who agreed as to the diagnosis of meningitis, most probably of tuberculous origin, and an unfavourable prognosis was given. There was marked diplopia and both external recti were now affected; the pyrexia continued and the acuteness of vision was distinctly lessened. On the 18th the girl's condition was pretty much the same and it continued so through the 19th. On the 20th her temperature was normal in the morning, there was much less headache, and the vomiting which had gradually been subsiding for two or three days now ceased. In the evening her temperature was 99·4° and thereafter she steadily improved and gained flesh. From this time there was practically no pyrexia but double vision lasted for more than a fortnight and the squint did not quite disappear until May, 1901, when the girl was well enough to pursue her occupation.

What was the condition which gave rise to this train of symptoms? There can hardly be any difference of opinion as to some form of meningitis having been present. As there was no history of injury, middle-ear disease, or influenza the most probable varieties would be either (1) a septic form occurring in the course of some concurrent disease which I think need not be further considered, or (2) a specific form of the disease as the syphilitic or tuberculous. Against the first of these two causes is the objection that by the most careful examination and minute inquiries as far as they could be made without hurting the patient's feelings or those of her friends no evidence of primary sore, secondary trouble, or congenital affection could be found and I am left to fall back on the theory that the exciting cause of the illness was the tubercle bacillus. The history of increasing debility, the gradual loss of flesh, the affected lymphatic glands of the neck, and the age of the patient incline me to take this view, although it may be argued that from the manner in which the disease gave way to the treatment by mercury and iodide of potassium the case was one of specific disease.

The question of recovery from tuberculous meningitis is one *in which I am much interested, as more than 20 years* ago I attended a case which was then diagnosed as tuberculous and in which also there was an affection of the apex of the left lung, and this patient, who was a boy, got well and is now working with his father as a blacksmith. The absence of tubercle in the choroid is not sufficient to negative the diagnosis, as it is only present in a small percentage of cases which are indubitably proved by post-mortem examination to be tuberculous.

Ilkley.

THE LIFE SPAN OF THE GUINEA-WORM.

BY S. ARTHUR POWELL, B.A., M.CH. R.U.I.,
SURGEON TO THE POLICE HOSPITAL; PROFESSOR OF BIOLOGY, GRANT MEDICAL COLLEGE, BOMBAY.

A PAPER on this subject by Sir Patrick Manson appeared last July.[1] In Sir Patrick Manson's cases the time of possible infection extended from February to June. In the cases under consideration the period of exposure in the endemic area was only two days. I am indebted for the particulars to Mr. M. Cursetjee and Mr. Fazalbhoy Chinoy. A party of 16 gentlemen with five servants, all residents of Bombay, a city with a good artificial water-supply, where guinea-worm is only seen in patients from the country, chiefly from the Deccan, left Bombay and reached Mahad on April 20th, 1902, where they all stayed for two days, drinking the water from a well without filtering it. They returned to Bombay on April 22nd. On April 2nd or 3rd, 1903, the first worm made its appearance in the leg of one of these gentlemen. Up to the first week in July worms to the number of nine continued to be discharged from his body. Doubtless, owing to injection with perchloride of mercury, the exit of some of these worms was delayed, as they were killed, and considerable cellulitis and suppuration ensued. The next patient was delivered of a worm on May 1st, 1903, and five other patients between that date and May 20th. Seven patients in all were attacked, six of the party of 16 and one of the five servants. Nineteen worms in all were extracted. None had come out since the first week in July up to Oct. 3rd. The shortest period in these cases was 345 days and the longest 435. The great majority of the worms appeared a year and two or three weeks after the date of infection.

The estimation of the life span of this worm in its human host is a matter of importance in prognosis in the case of persons exposed to infection. Thus I had no hesitation in informing the ten gentlemen who have not yet suffered that they have little reason to fear the appearance of worms, a matter of considerable apprehension to some of them. Inquiries were made among the inhabitants of Mahad as to the prevalence of this worm in the district. The replies indicate that about half the population suffered from guinea-worm during 1903

Two points of interest in connexion with this parasite may be mentioned here. There is frequently a considerable fever *a few days before the worm* becomes palpable. Two of those cases suffered from fever with swelling of the face and hands. The sensation of swelling and tension to the patient is greater than the appearance to the surgeon seems to warrant. This swelling of the face and hands I have frequently observed when the worm was in the lower extremities and seems independent of the situation of the parasite. The origin of this fever may be suspected from the absence of malarial parasites and an increase in the proportion of the eosinophile corpuscles in the blood. In a paper[3] read before the Bombay Medical and Physical Society I described six cases of guinea-worm infection in which examination of the blood showed 4·75, 5·5, 7·5, 7·5, 8·0, and 12·25 per cent. of eosinophile corpuscles respectively. The pus from one sinus contained 19 per cent. of eosinophiles.

Bombay.

SEVERE CASE OF ERYSIPELAS OF LEG FOLLOWING ULCERATION TREATED BY ANTISTREPTOCOCCIC SERUM; RECOVERY.

BY E. H. BLAKE, L.R.C.P. IREL., L.S.A.

THE patient whose case is now described was a single woman, aged 54 years. I was first asked to see her on Jan. 4th, 1904. On my arrival I found that she had been vomiting for some hours and as her history was an alcoholic one I prescribed a mixture containing carbonate of bismuth with bicarbonate of sodium and hydrocyanic acid. The next morning she seemed better but her sister, who was looking after her, asked me to see her leg. On the right leg was a large varicose ulcer which had not been dressed for some days and which smelt most offensively. Hot boric fomentations were ordered and the assistance of trained nurses was obtained. On the next morning erysipelas had commenced at the seat of the ulceration and quickly extended up the leg to the thigh. The patient now got rapidly worse in spite of treatment and on the evening of Jan. 8th her condition was desperate. The temperature was 105° F., the tongue was dry and brown, the pulse was feeble and irregular, and the patient was delirious. Antistreptococcic serum (from the Lister Institute of Preventive Medicine) was now injected. On the next morning the temperature was 100° and the patient seemed much better. Another injection of the serum was given. Since then the patient has made an uninterrupted recovery and is now convalescent.

Upton, B.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Observation on Metabolism in the Febrile State in Man.

A MEETING of this society was held on Feb. 23rd, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. G. C. GARRATT read a paper on Metabolism in the Febrile State in Man. The paper reviewed the literature of the subject and gave the results of analysis of the urine of febrile patients carried out during seven years' residence at the London Fever Hospital. The cases studied formed a long series, unusually uniform as regards age, sex, and condition; moreover, the diet during pyrexia was the same and contained no nucleins. In the absence of pyrexia the above diet was found to cause in persons kept in bed no retention of sodium or chlorine and a small loss of nitrogen. A study of the literature resulted in the conclusion that the reduced excretion of urinary water was merely the result of increased loss by other routes, often preceded by earlier diuresis and accompanied by diminished intake by the mouth. Dr. Hutchison's analyses, which showed little excess of water in febrile tissues, were confirmed by Dr. Garratt, who also pointed out that Leyden's work showed no absolute retention of water, but quite the contrary, and that others had greatly underestimated the insensible loss. Passing to sodium and chlorine, it was pointed out that reduced excretion of chlorine accompanied nearly all acute fevers except malaria, further that retention of chlorine might continue far into convalescence and bore no relation to retention of water. Again sodium and chlorine, given in combinations other than sodium chloride, were nevertheless retained and the return of the one did not necessarily coincide with that of the other. Dr. Garratt considered that no satisfactory explanation of the phenomenon had been produced, but inclined on the whole to that which assumed the chlorine to be retained in combination with albumin. He had, however, failed to find chlor-albumins in muscle after fever. Estimations of urea showed the usual increase resulting from fever and there was also a similar increase of uric acid. Further, it appeared that no close relation could be traced between this excretion and that of phosphates. In fact, while the uric acid was increased more than urea the phosphates showed on the average no increase at all. The conclusion drawn was that endogenous uric acid came from proteids rich in nitrogen and sulphur and poor in phosphorus. Excretion of ammonia was considered in special relation to that of acids and bases and Dr. Garratt concluded that, while more work on this subject was necessary, the evidence that acids caused the increased production was not convincing. The excretion of phosphorus and free acid tended to run parallel but while there was on the average a slight increase of the latter there was none of the former. It might be that more than usual was lost by the bowel, nevertheless Dr. Garratt concluded that the total output in the cases studied was not greatly augmented. Further there was no evidence that retention of phosphates occurred. The estimation of sulphuric acid exhibited an increase which was out of proportion to that of urea. Potassium was also increased but less so than urea; it showed a certain parallelism with phosphoric and also with sulphuric acid and played the principal part in combining with these acids. Dr Garratt suggested that some of the increase did not, therefore, represent metabolism of potassium holding tissues and that the output of phosphoric acid was a better guide thereto. The organism in these fevers appeared, in fact, to possess the power of selecting what proteids it would consume and to choose those rich in sulphur and nitrogen and to spare those rich in phosphorous and potassium. Calcium resembled chlorine, being excreted in abnormally small amount during fever. Magnesium was much reduced at first but increased later.

Dr E. I. SPRIGGS said that while working in association with Dr A. P. Beddard on metabolism in diabetes they had found a considerable increase in the acidity of the urine. Similarly in a case of acute rheumatism the acidity increased during the fever but fell directly the fever was over. The increase might be due to the excessive formation of acid or to an excessive nitrogenous metabolism. It seemed probable that the excessive nitrogenous metabolism played an important part, since if a healthy man was fed on a diabetic diet the acidity of the urine increased while he was on such a diet but subsequently became alkaline. When a man was breaking down a large amount of nitrogenous material a considerable quantity of acid was formed. The acidity was therefore probably not due to the fever but to the nitrogenous diet. Fever patients were in the main living on proteid. The ammonia present in the urine, as Dr. Garratt had shown, did not vary with the acidity of the urine and the ammonia was not produced in order to neutralise the acid. Dr. Spriggs propounded the following theory to explain the presence of the ammonia which could always be found in the urine. Ammonia was a normal product of cell metabolism in the body which became converted into urea in its passage through the liver. Such blood as did not pass through the liver would lose the ammonia it contained during its passage through the kidney. During febrile states the liver cells only in part converted the ammonia salts into urea and the unconverted ammonia would be excreted by the kidney. Such a theory would account for the variation in the amount of ammonia and the fact that even in health a small amount of ammonia was always present in the urine.

Dr. R. HUTCHISON, after speaking in the highest terms of the work which had been carried out by Dr. Garratt, said that he had worked especially at the excretion of chlorides in pneumonia. He had expressed the opinion that chlorides were retained in the fixed tissues. The work which Dr. Garratt had carried out showed that this was improbable but he thought that the chlorides might be retained in some combination with the albumins. Dr. Garratt's work also showed that the sodium might be retained not as sodium chloride but in some other combination. He had expected that the uric acid and phosphoric acid would, as the result of breaking down of nuclein, have run parallel, but, as Dr. Garratt had shown, this was not the case. The whole paper showed the extreme difficulty of estimating metabolic processes from examination of the products excreted.

[3] Examination of the Blood in 3400 Cases of Fever, Transactions of the Bombay Medical and Physical Society, September, 1903.

Dr. GARRATT replied.

MEDICAL SOCIETY OF LONDON.

Progressive Paralysis of the Insane.—Brachial Neuritis.

A MEETING of this society was held on Feb. 22nd, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Dr. T. B. HYSLOP read a paper on the various Progressive Paralyses met with in the Insane. After dealing with the subject of general paralysis of the insane and criticising many of the views which had of late years been put forward to support the theory that general paralysis was a clinical and pathological entity he proceeded to differentiate some of the more important of the progressive paralyses associated with insanity which were apt to be mistaken for "general paralysis of the insane." The following types of progressive paralysis as met with in the insane were then described: (1) those of toxic origin (alcoholic, syphilitic, febrile, uræmic, and poisons); (2) types due to lesions of the cerebral cortex, as in acute dementia, stupor, katatonia, hebephrenia, and atrophy; (3) types associated with various system lesions—viz , locomotor ataxy, spastic paraplegia (and other spinal lesions), hæmorrhagic focal lesions, and tumours; and (4) types of paralysis due, for instance, to injuries or sunstroke. With regard to alcohol he gave many arguments and clinical data in support of the view that alcohol *per se* did not produce a paralysis of the progressive type like so-called general paralysis. The various relationships of syphilis to progressive paralyses were then discussed and Dr. Hyslop differentiated the following types: (1) terminal syphilitic paralyses; (2) parasyphilitic progressive paralyses; and (3) congenital parasyphilitic progressive paralyses. He believed that syphilis alone was not accountable for the so-called parasyphilitic affections. These terminal progressive paralyses did not exhibit the lesions of syphilis, antisyphilitic medication was useless, and these paralyses were comparatively infrequent in the female sex. The Chinese and negroes were races in which syphilis was prevalent and yet they had hitherto proved to be almost free from tabes and progressive paralyses. These and many other considerations led him to seek other factors of causation than those which might fairly be regarded as syphilitic and evidence was fast accumulating which went to show that the defensive nervous mechanism was at fault in the terminal stages of syphilis. The rôle of stress and strain and the toxic influences at work as terminal infections were then discussed and the paper concluded with an outline of the various paralyses due to uræmia, cortical lesions, system lesions, and traumatism.—Dr C. E. BEEVOR remarked that the cases he had seen were of an earlier stage than those met with in an asylum. It was necessary to look for a group or combination of symptoms as an aid to diagnosis rather than individual symptoms, such as pupillary signs, alteration of the patellar reflexes, tremor, movements of the corrugator supercilii, and alteration of character (exaltation did not occur until the later stages). He agreed with Dr. Hyslop that alcohol *per se* was not a cause of general paralysis. Syphilis was very often in operation but not necessarily in every case. —Dr. E. MARRIOTT COOKE agreed that a great many diseases were confused under the term "general paralysis of the insane." The diagnosis was often very difficult in the early stages but not if the case was followed for some time. He agreed with the view of the French school that the disease was always grafted on a syphilitic basis. But there was always a superimposed cause, such as alcohol or sexual excess. —Dr. SIDNEY P. PHILLIPS asked for more information concerning the treatment of such cases with mercury or with iodide of potassium. The effect of these remedies would throw light on the causation.—Dr. J. VINCENT BELL remarked concerning those cases which started with a decay of the moral sense —Mr. J. PEEKE RICHARDS congratulated Dr. Hyslop in calling attention to the popular error of including a great many conditions under the name "general paralysis of the insane." He thought it was quite possible that in some cases the mental symptoms might be due to the too prolonged treatment by antisyphilitic remedies.—Dr. HYSLOP replied.

Dr. C. W. BUCKLEY (Buxton) read a paper on Brachial Neuritis. Pain was the most marked symptom, generally slight at first but becoming constant and severe, with paroxysmal exacerbations. The majority of cases seemed to arise from an injury which was often very slight, but the neuritis might not show itself until two or three weeks afterwards when the other symptoms had subsided. There was then a gradual recrudescence of pain with marked tenderness over the affected nerves and the usual features of a neuritis. Trophic changes in the joint often resulted. Gout and rheumatism were common causes and the cases having these origins might commence with an acute inflammation of the fibrous structures of the muscles which spread to the other fibrous tissues in the neighbourhood, and as the acute symptoms subsided the existence of a neuritis became obvious and generally ran a chronic course. A chill in a gouty subject was liable to give rise to such a condition but cases of gradual onset and extremely chronic course were also attributed to gout. Cases arising in women at the menopause were not uncommon and while some of these were gouty in origin the majority were probably toxæmic and belonged to the same type of neuritis as that occurring in pregnancy and the puerperium. Reflex causes were sometimes responsible, such as aneurysm, or a lipoma in the area of distribution of the plexus. The duration was probably never less than three or four months; it might extend over years and relapses were not infrequent. The keynote of treatment must be complete rest as long as any actual inflammation of the nerves (as shown by tenderness) was present. At first specific treatment for gout or rheumatism might be indicated; in cases of inflammation of the fibrous tissue the combination of aspirin with phenacetin was useful and the coal-tar analgesics were generally preferable to opium. Hot applications relieved the pain and galvanism had also an anodyne effect, but Dr. Buckley found the free use of blisters along the course of the nerves most useful. Massage must not be used as long as any marked tenderness existed. The high-frequency current had been found beneficial by some observers in chronic cases but it seemed probable that these were cases of neuralgia persisting as a habit after the disappearance of the nerve lesion. Hydro-therapeutic treatment by means of hot douches and vapour baths was often very effectual and the mineral baths of Bath or Buxton were of the utmost value, especially in rheumatic or gouty cases.—Dr. PHILLIPS remarked that swelling of the limb might occur in such cases and hyperæsthesia might be very marked and associated with effusion of the joints. Some cases started with influenza. Salicylates were useful in some cases but not in all. Aspirin was useful. The ice-bag was a most efficacious remedy, especially if applied to the spine. Massage was most injurious.—Dr. WILFRED HARRIS observed that cases of arthritic atrophy of the deltoid muscle might easily be mistaken for neuritis of the circumflex muscle and suggested that a traumatic lesion of the shoulder-joint might explain some of the cases referred to.—Dr. F. J. POYNTON, while doubting the existence of the reflex arthritic amyotrophy of older authors, suggested that cases of so-called brachial neuritis were sometimes due to rheumatic or gouty joint affections.—The PRESIDENT remarked that the coal-tar derivatives often failed to relieve the pain, morphine and atropine being the only efficacious remedies.—Dr. BUCKLEY replied.

OPHTHALMOLOGICAL SOCIETY.

Gonorrhœal Conjunc [illegible] Peroxide.—Congenital Anterior [illegible] of Cases and Specimens.

A MEETING of this society was held on Feb. 11th, Mr. JOHN TWEEDY, the President, being in the chair.

Dr. ADOLPH BRONNER read notes of a case in which a woman, aged 32 years, had had her Eye Inflamed for two days before being seen by him. The lids were swollen and a profuse discharge was present in which gonococci were found. Perchloride of mercury was used as a lotion as well as protargol (5 per cent.) to the lids and drops of 3 per cent. hydrogen peroxide were used every four hours. On leaving off the peroxide the cornea rapidly became ulcerated but on recommencing it the ulcer at once

ceased spreading and healed, leaving remarkably little scar behind. Excellent vision was obtained and Dr. Bronner had
never sc
covery.
said tha
hypopyon ulcer but had not tried it for purulent ophthalmia. The ulcer healed very well indeed without perforating or scarring.—Mr. GUSTAVUS HARTRIDGE said that years ago all cases of purulent ophthalmia at the Royal London Ophthalmic Hospital were treated with it but that for some reason or other it had been given up. He thought that protargol of weaker strength than 20 per cent. was of very little use.—Mr. W. T. HOLMES SPICER said that some years ago he published a large number of cases of purulent ophthalmia treated at the Royal London Ophthalmic Hospital and he found that those treated with silver did much better than when treated only with peroxide.—Dr. BRONNER, in reply, said that he did not at all advocate the use of hydrogen peroxide to the exclusion of silver and other remedies but in combination with them he was much impressed with its utility.

Mr. J. HERBERT PARSONS read a paper on Congenital Anterior Staphyloma. A girl, aged three days, was admitted to the Royal London Ophthalmic Hospital, under the care of Mr. J. H. Fisher, with an anterior staphyloma of the left eye. The condition was noticed at birth. The mother was healthy and the confinement was normal; the child was born immediately after rupture of the membranes; there was no other deformity. There were a very slight mucous discharge and a complete anterior staphyloma with no anterior chamber. The iris was adherent to the pseudo cornea which was very thin and almost transparent. Pathological examination showed the usual features of an anterior staphyloma, the lens being *in situ* and the whole eye in an early stage of panophthalmitis. The posterior chamber was full of polymorphonuclear leucocytes which were also present in the vitreous. The true cornea at the sides showed dense infiltration; the epithelium and Descemet's membrane were present here only. The anterior capsule of the lens was ruptured; the lens was cataractous but there was no anterior capsular cataract. Nine previous cases of congenital anterior staphyloma with pathological examinations had been reported. All the cases showed exactly the same features as were found when the condition developed in the usual manner after birth. It was probable that the intra-uterine cases were due to the same cause—namely, perforation of the cornea. Endogenous infection was improbable owing to the absence of blood-vessels in the fœtal cornea. Exogenous infection through the amniotic fluid was more probable. It was almost impossible to explain the cases on the theory of maldevelopment.—Mr. E TREACHER COLLINS and Mr. EDWARD NETTLESHIP discussed the case.

The following cases and card specimens were shown:—

Dr. A. OGILVY and Mr. SYDNEY STEPHENSON: Specimens of Epithelioma of the Ocular Conjunctiva.

Dr. ARNOLD LAWSON: Traumatic Aniridia.

Mr. N. BISHOP HARMAN: Nose-blinking movements.

Mr. HARTRIDGE: Unusual Opacity of the Posterior Part of the Lens and Capsule.

Mr. G. W. THOMPSON: (1) Double Kerato-iritis in an infant; and (2) Peculiar Changes of, and around, the Disc.

Mr. M. S. MAYOU: Two cases of Cerebral Degeneration from the same family associated with macular changes.

Mr. W. H. H. JESSOP: Epibulbar Tumour.

LIVERPOOL MEDICAL INSTITUTION.

Perforating Ulcer of the Stomach.—Perforating Ulcer of the Duodenum.—The Treatment of Malarial Fever.—The Treatment of Placenta Prævia.

A MEETING of this society was held on Feb. 18th, Dr. JAMES BARR, the President, being in the chair.

Dr. R. J. M. BUCHANAN and Mr W. THELWALL THOMAS related a case in which an operation had been successfully performed for Perforated Gastric Ulcer. The patient was an anæmic girl who was suddenly seized with acute abdominal pain for which she was admitted into hospital The diagnosis was at first doubtful; the continued elevation of temperature and a marked leucocytosis suggested the possibility of typhoid fever. The subsequent progress of the case, however, revealed a localised peritonitis which was thought to be most probably due to a perforated gastric ulcer. On the twelfth day of the illness Mr. Thelwall Thomas operated. The stomach and the liver were adherent to the abdominal wall and on separating these adhesions a localised abscess was opened and a distinct hole was seen in the stomach. An unsuccessful attempt was made to close the perforation with stitches and finally the abdominal wound was left open and packed with gauze. Convalescence was prolonged but the patient ultimately made a satisfactory recovery.

Mr. DAMER HARRISSON related a case in which he had successfully operated upon a man, 45 years of age, for Perforating Ulcer of the Duodenum. There had been no previous gastric symptoms. The patient was suddenly seized with acute abdominal pain which he referred more especially to the right iliac fossa An operation was performed 11½ hours after the onset; a perforated ulcer of the duodenum near to the pylorus was found and was closed with sutures.—Mr. T. C. LITLER JONES referred to a case in which perforation of a gastric ulcer had occurred at midnight; the patient finding that the pain was relieved by the knee-elbow position remained in that posture all night. At the operation next day there was an anterior perforation of the stomach with little, if any, extravasation but fair adhesions —Dr. E T. DAVIES, Mr. G. P. NEWBOLT, Mr. GEORGE G. HAMILTON, Dr. W. CARTER, and Dr. C. J. MACALISTER took part in the discussion on these cases.

Dr. CARTER read a note on the treatment of some cases of Malarial Fever. Four cases had come under his care during 1903 and they all more or less resembled each other. They were cases of obstinate continuance of fever and in spite of all the ordinary remedies there were complete breakdown of the general health and loss of weight. In every instance a complete and apparently permanent relief of all symptoms had followed upon the administration of Warburg's tincture. In one case the patient had suffered from frequent attacks of malarial fever during the last three years and during the last attack, in spite of the administration of large doses of quinine, the temperature rose to 106° F., but after a few doses of Warburg's tincture the temperature fell to normal, the general health markedly improved, and apparently permanent relief had followed.

Dr. H BRIGGS read a paper on the Treatment of Severe Cases of Placenta Prævia. By severe cases were understood one considerable or two or more recurrences of hæmorrhage, regardless of the degree of placenta prævia. The paper was mainly based upon the more modern means of treatment which promised to improve the results obtainable in the management of these cases. Dr. Briggs first alluded to the bag devised by Champetier de Ribes which, together with its forceps, presented an inconvenient and cumbrous appearance; hence possibly the comparative rarity of the use of the bag in the treatment of severe cases of placenta prævia. Its use could be rendered easy by preliminary dilatation of the cervix by the finger or by Bossi's method in the rare instances in which the latter was required. The 22 cases tabulated and the conclusions formulated in a paper by Dr. G. F. Blacker in the Transactions of the Obstetrical Society for 1897 were freely used by Dr Briggs. Dr. Briggs cited two severe cases of placenta prævia as illustrating the value of the treatment which he advocated: (1) in the twenty-eighth week of gestation when the cervix was closed, the bleeding was free, and labour pains were absent; and (2) a full-term labour with copious hæmorrhage In both the bag was used and in the former preliminary dilatation was effected by Bossi's instrument, which enabled the medical attendants to complete what had been a presumptive diagnosis and to introduce the bag of Champetier de Ribes, which served its purpose by controlling the bleeding and inciting and completing labour in eight hours. In the second case labour had commenced and was completed with a living child in the first vertex position in two and a half hours after the bag had been introduced. Dr. Briggs then referred to de Paoli's 19 cases of placenta prævia treated by Bossi's method, com-
pleted in from five to 25 min
cervix and with a death-rate of
Dr. Briggs expressed his opinic
of placenta prævia was becomi
He cited his own experience in six cases in which for grave maternal conditions he had used Bossi's method. As to the use of the bag, its great value consisted in its easy introduction, its standing boiling, and its perfect control of the bleeding, forming, as Dr. G. E. Herman had stated, a better hæmostatic wedge than the half-breech of the child after

turning. From his own experience of 30 cases treated by version he concluded that forcible delivery was rarely necessary, for in all these cases the bleeding had been controlled and without exception traction on the child was not required to check bleeding. It was probable that in many cases hæmorrhage from laceration of the cervix during podalic version was a source of bleeding due to the treatment adopted. The interests of the child were improved by the use of the bag of Champetier de Ribes and whenever the bag was available it ought to be used in the treatment of placenta prævia.—Dr. JOHN E. GEMMELL said that most cases of placenta prævia were of the marginal type and in these the use of the bag was not necessary. Further, the introduction of the bag necessitated the presence of a second medical attendant to administer an anæsthetic, which would render its general employment impracticable.—Dr. LLEWELLYN A. MORGAN relied upon tight packing as a routine treatment in cases of severe hæmorrhage.—Dr. F. HEATHERLEY, Dr. DAVIES, Dr. MACKAY, Dr. W. BLAIR BELL, and Dr. LITTLE also took part in the discussion and Dr. BRIGGS replied.

EDINBURGH OBSTETRICAL SOCIETY.

Hebotomy.—Nephrectomy and Exploratory Nephrotomy.

A MEETING of this society was held on Feb. 10th, Dr. N. T. BREWIS, the President, being in the chair.

Dr. D. BERRY HART read notes on a case of Hebotomy (lateral section of the os pubis). He said that the aim in obstetric practice was to find in difficult cases a satisfactory operation safe for mother and child. Thus in flat pelvis when forceps or turning failed, as when the conjugata vera was below three and a half inches, then it was expected that symphysiotomy would be resorted to down to two and three quarter inches. After that only Cæsarean section or craniotomy would be available. Objection was made to symphysiotomy on the ground of the difficulty of insuring asepsis, the possibility of injury to the neighbouring structures, and the risk of the resulting union not being immoveable. Hebotomy was the lateral section of the body of the os pubis avoiding the symphysis; the objections to symphysiotomy affected this operation in much less degree. It had been recently revived by Gigli of Florence who used a special wire saw for the operation. An oblique incision was made through the soft parts down to the os pubis; a director was passed behind the body of the bone, keeping close to it, and afterwards the special wire saw. The saw divided the bone rapidly and easily. Any bleeding was readily controlled by pressure. After the section the pelvis opened out and permitted of an easier passage of the child. The periosteum was then stitched together and afterwards the skin wound. Dressings were applied, a binder was firmly fixed, and sand-bags were arranged at the sides of the pelvis. Dr. Hart gave details of a case where in a woman's first confinement craniotomy was performed; in the second labour hebotomy was tried and the child was easily delivered with forceps. The patient unfortunately died on the third day from exhaustion with no local symptoms. The necropsy seemed to show acute fatty degeneration of the tissues, probably the result of the chloroform. She had suffered severely from chloroform sickness both after the previous and this labour. The death-rate at present was about 6 per cent. The amount of space gained was three fifths of an inch for two and a half inches of divergence.—Professor A. R. SIMPSON, Dr R. C. BUIST, Dr. A. H. F. BARBOUR, and Dr. F. W. N. HAULTAIN made remarks on the paper.

The PRESIDENT described four Renal Cases. The first of these involved the removal of a large pyonephrotic kidney weighing 45 pounds and having the following dimensions, greatest circumference four feet, greatest diameter 15 inches, and greatest thickness ten inches. On section of the tumour no kidney substance could be distinguished with the naked eye but the organ appeared to be converted into a loculated cyst containing liquor puris and pus cells. The main cyst was divided into several loculi which were distinct but communicated with the renal pelvis by small rounded openings in which three rough calculi were present. A large calculus obstructed the ureter. The patient was known to have a renal swelling for 25 years. In 1875 she was known to have had a floating kidney and in 1888 a renal tumour. She could neither lie down nor sit on account of the great size of the tumour. Dr. Brewis performed [illegible] patient was now in good health. The second case [illegible] of tuberculous kidney and ureter and nephro-ureterectomy was performed. On examination the enlarged [illegible] and ureter were easily felt. Both ureters were [illegible] The urine from the right ureter contained tubercle [illegible] but none were found in the sample from the [illegible] bladder was healthy except in the region of the [illegible] ureteric orifice. The freezing point of the blood was normal. The kidney and ureter were removed. The ureter just below the renal pelvis had a circumference of four inches and was adherent throughout its whole extent. When the patient left the hospital no tubercle bacilli could be found in the urine. She was now well and strong. [illegible] the third case there was adenoma of the suprarenal body. The patient, who was 41 years of age [illegible] six times, had observed [illegible] years and had lost two stones [illegible] years. She had had four [illegible] abdominal swelling had [illegible] removed and the kidney with [illegible] In the fourth case exploratory [illegible] performed. The patient, who was 43 years of age, had been pregnant eight times, first noticed blood [illegible] urine four years ago; during the last four months the bleeding had been frequently very profuse. With the cystoscope blood was seen coming from [illegible] the urine from the right ureter was [illegible] President cut down on the left kidney and found it to be universally adherent and uniformly enlarged. He made a longitudinal incision in the middle [illegible] substance of the kidney, dividing [illegible] Nothing abnormal was found in the [illegible] presented the appearance of chronic [illegible] The two halves were stitched together [illegible] catgut sutures and the kidney was returned. The patient recovered and had had no hæmaturia since.—Professor SIMPSON, Dr. HART, Dr. HAULTAIN, Dr. J. W. BALLANTYNE, and Dr. W. FORDYCE discussed the paper.

GLASGOW NORTHERN MEDICAL SOCIETY.—A meeting of this society was held in the Western Infirmary on Feb. 19th, Dr. J. G. Connal being in the chair.—Dr. D. J. Mackintosh showed ten patients who had been under [illegible]ment in the electrical department. Some of them had been treated by the x rays alone and some by the x rays combined with Finsen's application of light. Six of them suffered from lupus, one from rodent ulcer, one from epithelioma, and two from tuberculous disease of the hand. In two cases the lupus was quite healed and in six of the others there was more or less improvement.—Mr. J. Walker Downie gave a demonstration on Suppurative Affections of the Accessory Sinuses of the Nose, illustrated by lantern slides, patients, and specimens. He said that these sinuses were divided into an anterior and posterior set, the anterior set consisting of the frontal sinus, the anterior ethmoidal cells, and the antrum of Highmore, while the posterior set consisted of the posterior ethmoidal cells and the sphenoidal sinus. The antrum of Highmore might become the seat of simple catarrhal inflammation with secretion of mucus. This condition was frequently associated with [illegible] catarrh and tended to spontaneous recovery if the [illegible] but if it became blocked suppurat[illegible] suppurative condition might also ari[illegible] of the nose or from influenza. In such [illegible] plained of pain over the cheek and [illegible] intermittent, unilateral discharge and [illegible] of the cheek. A unilateral purulent [illegible] the adult was probably due to an antra[illegible] child such a discharge was generally due to a foreign body. In these cases an odour was complained of by the patient which was not perceived by those around, whereas in ozæna the patient, owing to the sense of smell being blunted, did not notice the odour which was marked and offensive. Pus in the middle meatus might come from the frontal sinus, the anterior ethmoidal cells, or the antrum. In order to arrive at a diagnosis the meatus should be wiped out and the postural method tried; the meatus should then be again examined and if the pus came from the antrum a bead of it would generally be seen at the ostium. [illegible] method of diagnosis was by transillumination, performed with a lamp in the mouth, with the lips closed, in a darkened room. If the antrum was healthy it was generally fairly translucent, whereas if it contained pus it was opaque. The diagnosis might be completed by tapping the cavity through the nasal wall, the canine fossa, or an alveolus after extraction of a tooth. In acute cases the treatment consisted in the use of hot fomentations, soothing steam inhalations, and intranasal applications to reduce turgescence and to cleanse the surfaces. When these failed to relieve the cavity it might be tapped. In chronic cases all sources of intranasal obstruction, such as polpyi, hypertrophied bone, and mucosa, should be removed. If the discharge persisted Mr. Downie recommended the performance of a radical operation through the canine fossa under a general anæsthetic. He spoke against the common practice of tapping and *draining through an alveolar opening*. He next described the frontal sinuses and gave full details of the operation for exposing the sinus in cases of frontal sinusitis after all intranasal lesions had been rectified. In conclusion, he referred *shortly* to suppurative affections of the ethmoidal cells and of the sphenoidal sinus

Midland Medical Society.—A meeting of this society was held on Feb. 17th at the Medical Institute, Birmingham, Dr. W. G. Lowe of Burton-on-Trent being in the chair.—Mr. L. P. Gamgee showed a woman, aged 46 years, who in October, 1901, suffered from a severe attack of Right Hypochondriac Pain accompanied by Jaundice. This passed off and she was then free from symptoms for a year and ten months During August and September, 1903, she had numerous attacks of pain and was continually jaundiced, the degree of the jaundice varying. At the beginning of October she had great tenderness on pressure

between

swelling

position.

On Oct. 18th the abdomen was opened and the biliary apparatus was explored. No calculus was found and no obstruction to the ducts could be made out. The head of the pancreas was hard and markedly enlarged. The gall-bladder was stitched to the skin and a fistula was maintained for three months. At the present time some fulness could be felt in the old position but there was no distinct swelling and the tenderness had almost disappeared. The attacks of pain and jaundice had not recurred. The case was presumably one of chronic inflammatory enlargement of the head of the pancreas.—Dr. O. E. Purslow showed a Cystic Tumour of the Uterus. The patient, who was 24 years of age and married, with one child, was admitted to the Queen's Hospital, Birmingham, on Nov. 12th, 1903, with a cystic swelling of the abdomen reaching to two inches above the umbilicus and *presenting* all the physical signs of an ovarian cystoma. The swelling had been first noticed six weeks previously and both the patient and the medical man under whose care she had been thought that it was growing rapidly. *Abdominal section* was performed. The cyst when exposed had the appearance of an ovarian cyst. It was tapped and a large quantity of thin yellow fluid escaped from two separate locules. On commencing to remove the cyst it was seen to be growing from the fundus uteri, spreading out widely into each broad ligament and having extensive adhesions to omentum and intestine. The operation was difficult and prolonged; it was found necessary to amputate the uterus at the level of the internal os. The patient made an excellent recovery.—Mr. H G. Barling read a paper entitled "Notes on Gastro-jejunostomy, with a Comparison of Various Methods." The posterior operation was recommended, the jejunum being taken up through an opening in the transverse mesocolon. Mr. Barling based his experience of this operation upon a record of 18 cases, of which 16 recovered. The methods of union by Murphy's button, by Robson's bone bobbin, and by suture were discussed and the last was advised as providing a wider opening than either of the others.

British Gynæcological Society.—A meeting of this society was held on Feb. 11th, Professor John W. Taylor, the President, being in the chair.—Dr. William Duncan read notes on a case of Early Rupture of a Tubal Gestation and with the epidiascope illustrated the mode of the imbedding of the ovum by microscopical sections which showed that the gestation sac was separated from the lumen of the tube by muscular tissue. We publish this paper *in full* at p. 563 —*After discussion*, in which the President, Dr. J. J. Macan, Dr. Herbert Snow, Mr. W. D. Spanton, Mr. Christopher Martin, and Dr. H. O. Pope took part, Dr. Duncan explained his preference for suture of the *abdominal wound in layers, which in ordinary circumstances* did not take more than a couple of minutes, and pointed out that the ovum not merely found its way into the musculosa of the tube but its port of entry completely closed up.—Dr. H. Macnaughton-Jones showed an Aseptic Cap for the Mouth and Nose supported on a spectacle frame and devised by himself, which he thought equally effective and less cumbersome than others recommended. He read notes of a case of General Vesicular Eruption following a dressing of Iodoform and pointed out that an idiosyncrasy against that drug might exist and should be ascertained —Dr. Snow read notes on a case of a Cyst *simulating Femoral Hernia*, and Mr. *Spanton made a short* communication on Woollen Fibres as a cause of Bladder Irritation in Girls, relating three cases in which such trouble had been due to the wearing of coarse woollen under-garments *the fibres of which were detected in the* urine.—The President, after thanking Dr. Snow and Mr. Spanton for their interesting communications, proceeded to read his Inaugural Address, an abstract of which was published in our columns last week.

Medico-Legal Society.—A meeting of this society was held on Feb 9th, Sir W. J. Collins, the President, being in the chair.—A paper was read by Mr. J. H. Targett on Homicide by the Introduction of Foreign Bodies Specimens were shown in a recent case where a man confessed after some ten years to having murdered his child, aged ten months, by pushing three corks into the back of the mouth, two of which were found, as seen in the specimen, in the stomach; the third, a larger one, was impacted in the upper end of the œsophagus —This led to an interesting discussion in which Earl Russell, Dr. F. J. Smith, Dr. F. J. Wethered, and others joined. It appeared that in parts of the Midlands there was a practice of placing pieces of cork and sponges in the food of cats with a view to causing obstruction of the bowel and death —A second paper was
read by Professor A.
by Drugs, especially
also read by Dr. S.
cussion upon which was postponed until the meeting on April 19th —Nine new members were elected, amongst whom was Sir Joseph Walton, one of the judges of the High Court.

Æsculapian Society.—A meeting of this society was held on Feb. 19th, Dr. Leslie Durno, the President, being in the chair.—Dr. H. P. Miller gave a demonstration of Eye Diseases, including interstitial keratitis; iritis with punctate keratitis; coloboma of irides and of one lens; a boy with normal vision whose cornea, iris, and lens had been pierced accidentally by a piece of steel and surgically removed; opaque nerve fibres in a myope; congenital rhythmic semiclosure of the left orbicularis oculi in a girl, aged nine years, associated with mastication; and orbital tumour with proptosis in a rickety child aged 18 months. A diagnosis of hæmorrhage was made.—Dr. David Ross showed a man, aged 20 years, who a year ago began to pass an Excess of Urine He passed now on an average 22½ pints of urine and drank 20 pints of liquid in 24 hours He was losing weight, strength, and appetite The urine was clear, with specific gravity 1001, and contained neither sugar nor albumin. The rarity of the state was noted.

Hunterian Society.—The annual meeting of this society was held on Feb. 10th, when the following elections were made Council:—President: Dr. Frederick J. Smith Vice Presidents: Mr. John Adams, Mr J. H. Targett, Dr. John W Oliver, and Dr. T. H. Arnold Chaplin. Treasurer Dr. R Hingston Fox. Trustees: Mr. F. M. Corner, Mr. F. Gordon Brown, and Mr. R. Clement Lucas. Honorary Librarian: Dr. William Rawes. Honorary Secretaries: Dr. T. Glover Lyon and Mr. Harold L Barnard. Dr. H. Russell Andrews, Dr. S. H. Appleford, Dr. Arthur T. Davies, Mr. W. H. Best, Dr. J. H. Bryant, Dr. R. Fortescue Fox, Dr. W. J. McCulloch Ettles, Mr. A. W. Galloway, Mr. F. Rowland Humphreys, Dr. W. Henry Kelson, Dr. Herbert V. Hickman, and Dr. William A. Dingle. Editorial Secretary: Dr. Edward W Goodall. Auditors: Mr. Brown, Dr. Davies, Dr. G. Newton Pitt, and Dr. Smith

Reviews and Notices of Books.

Clinical Pathology of the Blood: a Treatise on the General Principles and Special Applications of Hæmatology. By JAMES EWING, A.M., M.D., Professor of Pathology in Cornell University Medical College, New York City. Second edition, revised and enlarged. Illustrated with 43 Engravings and 18 Coloured Plates drawn by the Author. London: Henry Kimpton. 1904. Pp. 495 Price 21s.

IN our review of the first edition of this work we spoke favourably of the scope of the book and of the manner in which Dr. Ewing had carried out his labours. We have no reason to alter our views after a perusal of the second edition. During the two years which have elapsed between the publication of the volumes the contributions to the knowledge of the blood in both its clinical and its pathological aspects have been very numerous and in many instances of fundamental importance. Dr. Ewing has succeeded in incorporating the results of these recent studies in a form which is useful and available both for the medical practitioner and for the student of hæmatology. Considerable additions have been made to the chapter on Technics. A full account is given of the "medico-legal serum diagnosis of blood." Dr. Ewing asserts that one fruitful result of the recent trend of study of the mechanism of immunity has been the discovery of a delicate and fairly trustworthy method of distinguishing human blood from that of the lower animals. The first step in the elaboration of this method of serum diagnosis consisted in the discovery by Tschistowitsch that the serum of an animal treated by injections of defibrinated blood or of serum from another species of animal develops the power of agglutinating and dissolving the red cells or of causing a precipitate in the serum of the second animal. Investigations by other observers have shown that this principle can be applied to the identification of blood for medico-legal purposes and that it is possible thereby to determine the origin of old blood stains. The mode of preparing the necessary serum is minutely described but the process is an elaborate one. The delicacy of the test, however, seems to be very great, a reaction having been obtained in solutions of blood too weak to give the absorption spectra and in solutions of 1 of serum to 50,000 of blood. After reading Dr. Ewing's remarks we agree with him that there are many difficulties in applying this test and that an absolutely faultless technique is required The proceeding is one which should be carefully investigated, as if satisfactory results can be obtained a great step in advance will have been made in the requirements of forensic medicine.

A paragraph in the first chapter is devoted to the subject of Cryoscopy. It has been shown that certain clinical deductions can be drawn from the determination of the freezing point of the blood. The results arrived at by various observers are here recorded. The apparatus employed in applying the test is described as is the method of using it. Dr. Ewing quotes Dr. Carrara who found cryoscopy of the blood serum the most trustworthy test for the medico-legal diagnosis of death by submersion. Dr. Carrara maintains that the absorption of fresh water through the lungs, gastro-intestinal tract, and skin raises the freezing point of blood serum, while salt water lowers it, in each instance more markedly in the left than in the right side of the heart.

In Chapter III., on the Morphology and Physiology of Red Cells, much new matter has been added. An excellent account is given of the varieties of the red cells and the pathological changes which they may undergo. Especially worthy of note are the remarks on the influence of therapeutic measures on these cells. The changes produced in them by the absorption of iron, arsenic, mercury, and lead are discussed in detail.

In no other department is the examination of the blood to be interpreted with greater certainty in one case or with greater reserve in another than in its application to the various types of leukæmia, and the chapter on this condition now includes the most noteworthy additions to medical knowledge on this subject. Under certain conditions the changes in the blood may yield positive diagnostic signs of leukæmia, whilst in other circumstances the changes may justify only a probable diagnosis. The occurrence of intercurrent infections seems to have a considerable effect in preventing an absolute diagnosis being possible. Again, in some stages of leukæmia the blood may fail to furnish indications of the nature of the disease which may then be overlooked. Most writers seem to agree that the early stages of the disease often escape detection and also that many spurious cases have appeared in medical literature, a false diagnosis having been arrived at.

In the chapter on the Leucocytes and Leucocytosis the essential features of Ehrlich's theories on immunity have been presented but Dr. Ewing points out that the limits of the volume do not permit full discussion of this subject.

Part II. of the work, which is devoted to the Special Pathology of the Blood, contains a vast amount of interesting information. The condition of the blood in the various acute specific diseases is carefully considered and the latest views are incorporated. The criticism of Widal's test for typhoid fever will be read with interest, as this diagnostic measure is now very extensively used. Dr. Ewing asserts, and the majority of medical practitioners who have had experience of the test will doubtless agree with him, that the difficulty in determining the value of the test in diagnosis arises principally from the divergent opinions regarding the essential features of a complete reaction. The belief in the specific quality of Widal's reaction has been almost abandoned; but, nevertheless, we agree with Dr. Ewing that the test remains an extremely valuable diagnostic procedure under several conditions. As in the case of other bacteriological tests used for clinical purposes—e.g, the search for tubercle bacilli in the sputum—a negative result is of little import unless obtained during the height of the disease (from the third to the fifth week) and on repeated examinations. In the great majority of cases the reaction disappears within a few weeks after convalescence. We can confirm Dr. Ewing's assertion that authentic cases, some of them fatal, have not given a positive reaction at any time during their course.

Dr. Ewing's work is a valuable contribution to the knowledge which at present exists with regard to the clinical pathology of the blood and we can cordially recommend it to our readers as a trustworthy book of reference.

First Dressing on the Battlefield. By Colonel NICHOLAS SENN, M.D., Ph.D., LL.D Chicago, Ill., Surgeon General of Illinois; Lieutenant Colonel and Chief of the Operating Staff with the Army in the Field during the Spanish-American War; Professor of Surgery, Rush Medical College. Reprint from the *Journal of the Association of Military Surgeons of the United States.* Carlisle, Pennsylvania: The Association of Military Surgeons. 1903 Pp 40.

THIS is a publication which may be read with profit and interest by civilian and army surgeons alike. It gives a brief history of the subject of which it treats, with the views and opinions that have been expressed by different authorities, together with those which have commended themselves to the author after having been carefully thought out by him and tested experimentally on the battlefield. As to the value of a first-aid dressing in war in preventing infection of wounds there can be no doubt. Ample experience has been accumulated in proof thereof and it has become generally recognised that the first and most important thing to be done for a soldier in the fighting line is to provide him when wounded with an early and secure application of a first dressing. It is mainly in regard to what is the best and most effective system and method of doing this and as to various points of practical detail that any difference of opinion or practice can be said to exist. During the Spanish-American war it was found that many of the dressings became displaced before the wounded reached the field hospitals and infection could often be traced to this. The necessity of providing a means of direct fixation of a dressing as an essential component part of the first-aid package consequently became apparent. This was met by including some strips of rubber adhesive plaster of American manufacture in the package. After varied observations and experience in the Greco-Turkish and Spanish-American wars Colonel Senn formed very definite conclusions—which it is the purpose of this pamphlet to set forth—in reference to what a field dressing should contain and what may be expected from it by a timely resort to its use in the field. It goes without saying that the package must be as light and small as possible, simple in its make-up and application, and yet containing everything essential to protect the wound against subsequent infection. He recommends the employment of boro-salicylic powder as the antiseptic to be relied upon and in the course of a few pages, beginning at page 17, there is a full and illustrated description of the package and dressings devised by Colonel Senn showing the manner of their application with gauze roller and adhesive plaster. We need not accompany the author throughout his observations and comments which strike us as, speaking generally, practical and sound. At the end of his pamphlet he sums up these in 25 conclusions. If any of our readers cannot peruse the pamphlet as a whole (as we advise them to do) they might at any rate consult these conclusions with advantage.

Handbuch der Geburtshulfe. (*Handbook of Midwifery.*) By Numerous Writers. Edited by Professor F. VON WINCKEL. Vol. I, Part 1. With numerous tables and illustrations. Wiesbaden: J. F. Bergmann. 1903. Pp. 657. Price 13 60 marks.

WHEN we remember the position which Professor von Winckel holds in the profession, the numerous writings which have appeared from time to time from his pen, and above all his excellent "Lehrbuch der Geburtshülfe," one of the best text-books on midwifery, we are delighted to see that he is responsible for the editing of the new "Handbuch der Geburtshulfe." The numerous advances which have been made in all branches of obstetric medicine during the last few years, and especially in the science of obstetrics, render the publication of such a work doubly welcome. The names of the large number of well-known authorities whose coöperation Professor von Winckel has secured are a sufficient guarantee that when finished this treatise will be a most complete and authoritative work. A book of this character, containing all the newest facts and theories in the science and art of obstetrics and a complete bibliography of recent writings, cannot fail to be of the greatest assistance to all those engaged in this special branch of medicine.

The first volume opens with a most interesting survey of the history of midwifery from the earliest times to the end of the nineteenth century. This is contributed by the editor himself and is illustrated by an interesting series of engravings of celebrated obstetricians from Hippocrates onwards. The rest of the volume is devoted to a consideration of the anatomy, physiology, and symptomatology of pregnancy. The first two chapters by Strassmann are concerned with the beginning of pregnancy, including an account of menstruation and ovulation and dealing with the changes in the ovum consequent on impregnation and the early stages of its development. The third chapter, one of the most interesting in the book and exceedingly well written by Pfannenstiel, is on the Changes in the Uterus consequent on Pregnancy, the Imbedding of the Ovum, and the Formation of the Early Placenta, Membranes, and Cord. The subject is very completely and fully discussed, occupying some 100 pages, and is elucidated by a number of most excellent drawings. The succeeding six chapters are devoted to an account of the anatomy of the fœtus, the placenta, and the liquor amnii and of the changes taking place in the maternal organism during pregnancy, and are written by von Rosthorn. He also describes the changes in the pelvic organs occurring during pregnancy. Under the Symptomatology of Pregnancy Goenner writes a description of the uterus and its contents during the various months of pregnancy, the minor disorders of this condition, and the position of the child in utero. The last two chapters are by von Winckel and deal with the subjects of Auscultation and the Duration of Pregnancy. It is impossible in the space at our command to consider these articles in detail. They are all of the greatest excellence and the work is likely to be a classic on the subject for some time to come. The volume contains numerous illustrations and tables and the whole is worthy of the high reputation of its editor.

LIBRARY TABLE.

Health, Wealth, and Wisdom. London: Methuen and Co. Pp. 212. Paper covers. Price 1*s.* net.—The names of the authors of this book are not given but we are told in a note that Part I.—that on Health—is by a "medical writer," presumably, therefore, by a medical man (but this, though implied, is not distinctly stated), and that Parts II. and III., those on Wealth and Wisdom, are written "by another hand." The first part is the one which would have naturally most appealed to us but the publishers directed our attention specially to the other two sections—possibly to divert us from the first, for who can fathom the thoughts of a publisher?—and by chance it happened that we first read the sections on wealth and wisdom. Now although the members of our profession excel in the latter quality they lack often wealth and on the whole probably the members of no profession, with the possible exception of the clerical, are more careless in matters of business. The part of this little book which refers to wealth is really very suggestive and quite entertaining. The wisdom of Solomon and the platitudes of the late Dr. Parker are here strung together with a lively commentary. The mistakes of Mr. Joseph Chamberlain of Birmingham, of Mr Seddon of New Zealand, and even of Rudyard Kipling himself are shown up impartially, and the teachings of Socrates and of the late Mr. Matthew Arnold are quoted and praised on occasion. There is a healthful and easy breeziness about the writing which is quite inspiring in a critical age and those who have the industry to read through this part of the book with the satisfaction of thinking they knew it all before will possibly not be able to say with equal assurance that they carry out all the maxims which it contains. They will admit that many well known facts have been brought before them in a new light and not a few may feel that if they did really know these things it would be the better if they had done them. Briefly, much good advice is pleasantly given. To the medical man the chapter on Health will be amusing rather than instructive "A question that everyone should at times ask himself is, Am I healthy?" So the author teaches (p. 10) and everyone should ask himself, "Am I making the best of life?" However old or young you may be, says the writer, your health is not up to the mark if amongst other things you are "gloomy and depressed" or are "capricious in temper" or have "uneasy feelings of any sort." In any such case you should consult a physician. "The question of cleanliness brings us face to face with the microbe" (p. 13). (This seems to demand illustration.) Concerning microbes, there is an improving conversation between the learned author and an old lady. *Apropos* of baths, the author introduces his own personality for which he observes he may be pardoned. We may pardon him because of his modesty. Having coughed up blood three weeks previously and being as "weak as a weasel" on a foggy December day he felt disinclined for a "cold tub." But his second self whispered that he was a Scot and he must not be afraid. "So the man stripped"—and here we may leave him. The industrious reader may learn from these pages that we must if we would be healthy have flowers in our bedrooms, but the same flowers should not be kept for more than a fortnight (p. 36); that cheese should be taken at the beginning, not at the end, of dinner (p. 42); that honey is a tonic (p. 53); and other strange things. Our bold Scot likes "to see a prettily dressed girl, even although she does tight lace a bit" (p. 37). "Half a tankard of good ale is preferable," he says, "to the best wine in the world" (p. 43). There is no indication as to the source of "the best wine in the world" or as to where the happy author found it. We ought not, perhaps, to assume that it is the "speck of Scotch" alluded to elsewhere in the book

Banks and their Customers: a Practical Guide for all who keep Banking Accounts from the Customer's Point of View. By HENRY WARREN. An entirely new and enlarged edition (the seventh). London: Effingham Wilson. 1904. Pp. 155. Price 2*s.* net.—Although many people have a banking account it is astonishing how little the average man knows about the banking business. That a book on this subject was wanted is abundantly proved by the fact that the present volume represents the seventh edition of one published by the author. We say represents, rather than is, the seventh edition because little remains of the original work and some of the chapters now printed for the first time are entirely new. It is certainly not too much to say that most people who have anything to do with bankers are sure to find in this volume a good many things which it is well for them to know and which will remove at once and for ever the undue respect which many of them have for moneymongers, to use the title bestowed upon them by Kinglake in "Eothen." Some of the customs of the trade seem hardly, according to the author, to commend themselves on the score of honesty. The chapter on Recent Bank Robberies is amusing as well as valuable and one on the Choice of a Banker will be found generally useful.

The Care of Infants. By Dr. SOPHIA JEX BLAKE. Second edition. Edinburgh: George A Morton. London: Simpkin, Marshall, and Co., Limited. 1903. Pp. xiii.–109. Price 1*s.* net.—This is a little book written by a lady doctor for the benefit of mothers. The guiding principle which has actuated the authoress throughout her work has been that prevention is better than cure and doubtless much illness and subsequent disappointment would be avoided by mothers if even a fractional part of the very sensible advice offered in these pages was conscientiously followed. In Chapter I. the importance of breast-feeding is emphasised and the indiscriminate use of drugs is deprecated, and even the early dose of castor oil with which most children are ushered into the world is stigmatised as a meddlesome proceeding "which anticipates the gentle work of nature by an hour or two at the cost of gripes and cries." In those cases in which breast-feeding is inapplicable or impossible cow's milk, diluted with water and sweetened with sugar, is recommended and, further, for those cases in which casein is found to disagree it is suggested that the excess should be removed by the "Frankland method." This is an antiquated method and an unsatisfactory one because to insure the removal of the casein the milk has to stand for 12 hours and its natural qualities are further interfered with by artificial coagulation with rennet. Although we regard the authoress's condemnation of artificial foods for young infants as justified by experience we cannot agree with her that gruel made with fine oatmeal "is excellent" for infants of the age of five or six months. The indigestible cellulose which it necessarily contains exercises an irritating action on the bowel of older children not to speak of those of infants of such a tender age. A chapter is devoted to vaccination and its advantages are eloquently advocated. Another chapter is occupied with minor ailments of children with their appropriate treatment, which, by the way, is little concerned with drugs. Clothing and baths are also adequately described in independent chapters. "The Care of Infants" is a perfectly safe guide to put into the hands of young mothers and there is no encroachment on the just domain of the family medical adviser; indeed with the exception of certain recommendations for feeding we are in agreement with most of the advice which the authoress has incorporated in her very readable little book.

The Guide to South Africa, 1903–1904 Edition. Edited annually by A. SAMLER BROWN and G. GORDON BROWN for the Union Castle Mail Steamship Co., Limited. London: Sampson Low, Marston, and Co., Limited. Cape Town, Port Elizabeth, and Johannesburg: J. C. Juta and Co. Pp. 474. Price 2*s.* 6*d.*—This work, for the use of tourists, sportsmen, invalids, and settlers, contains a vast amount of information and many good maps. The historical chapters are most interesting reading but we see that an error to which we called attention in our review of the 1902–03 edition still remains. We refer to the passage on p. 260: 'Three species of ibis are found, including the sacred red ibis (ibis Æthiopica)." As we said before, the sacred ibis is not red but black and white. Moreover, the red ibis (eudocimus ruber) is only found in America. This mistake should be corrected.

JOURNALS AND MAGAZINES.

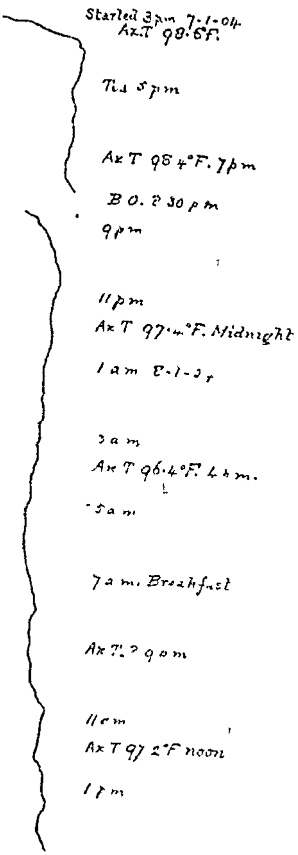
Technics.—This is a monthly magazine which Messrs. George Newnes of Southampton-street, Strand, London, W.C., have just commenced to publish. The first two numbers—i.e., those for January and February—contain articles which will be likely to interest many of our readers. The paper on the Diagrammatic Illustration of Class Lectures, of which Parts I. and II. have appeared, will supply useful hints for lecturers and authors of papers to be read before societies. The New Chemical and Physical Laboratories of the Royal College of Science, South Kensington, form the subject of articles by Professor W. A. Tilden and Sir Arthur Rücker. The Bacteriology of Brewing will be treated in a series of articles by Mr. James Grant, F.C.S., of which Part I. has appeared. A variety of electrical subjects are treated by well-known authorities on electrical physics, such as Professor W. H. Barrett, Mr. W. Brown, Mr. James Swinburne, Mr. H. M. Hobart, and others. Each of the first two parts contains rather more than 100 pages and is profusely illustrated.

THE GENERAL HOSPITAL, BIRMINGHAM.—On Feb. 12th a presentation was made to Dr. E. Malins by the governors of the hospital to commemorate his services of 25 years as the first obstetric officer to the institution. The subscribers were 152 in number with Sir John Holder as chairman. The memorial consisted of a stained glass window placed in the chapel of the hospital by the wish of Dr. Malins. There was in addition a valuable collection of silver plate with an illustrated bound copy of the resolution passed by the board on the resignation of Dr. Malins. The gift also included a gold brooch set with a large opal surrounded by diamonds for Mrs. Malins.

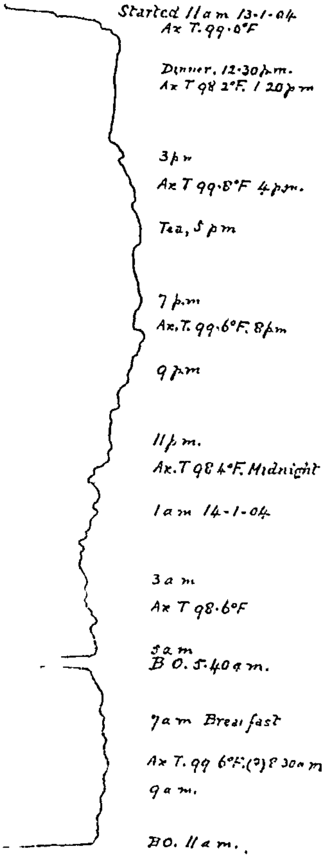
New Inventions.

THE PLATINUM THERMOMETER AND CALLENDAR ELECTRIC RECORDER FOR OBTAINING CONTINUOUS CLINICAL TEMPERATURE CHARTS.

HAPPENING to read some time ago of Professor Callendar's apparatus for obtaining continuous records of varying temperature, I conjectured that it might prove as useful for clinical work as it had done for scientific experiments and for factories. The Cambridge Scientific Instrument Company (Carlyle-road, Cambridge) was kind enough to lend me the apparatus and Dr. W. B. Warrington, of the Northern Hospital, Liverpool, very kindly placed his patients at my disposal for the trial, and I am now venturing to publish two complete 24-hour records of two cases. One was a case of granular kidney, cerebral hæmorrhage, and left hemiplegia, and the other was a rare case of osteo-arthropathy (probably tuberculous); the charts, however, are not given for any intrinsic interest but as examples of the utility and delicacy of the instrument in such work. So far as I can ascertain they are the first charts of the kind published, but I should add that, according to the Cambridge Scientific Instrument Company, Dr. C. H. Reissman, of the Middlesex Hospital, formerly made some experiments in the same line. I hope that Dr. Warrington will be able to continue the observations and believe that the apparatus is not only likely to prove clinically useful in many ways but may make interesting disclosures regarding the temperature both in health and in disease.



Case 1.—Hemiplegia



Case 2.—Osteo arthropathy

The platinum thermometer employed is of about the size of an ordinary clinical thermometer and is connected by long flexible wires to the recorder. In the two cases mentioned it was kept in the rectum for the 24 hours, the recorder being placed on a table at the bedside. Within the recorder a style charged with ink inscribes the temperature of the rectum on a chart fixed to a cylinder which revolves by clockwork once during the period. The nurses in charge of the cases made pencil notes from time to time on the same chart in a line with the style, regarding the axilla temperature (taken by an ordinary thermometer), the meals, and so on, being careful to record also the time at which the note was made. This process enables us to dispense with the previous standardising which would otherwise be necessary and also serves as a check. It will be observed that the record is interrupted when the bowels acted, the thermometer taking some time to become warm again after removal. The delicacy of the instrument is demonstrated by the wide amplitude of the curve, even with such small fluctuations (amounting only to about 2° F.) as occurred in the cases.

The Cambridge Scientific Instrument Company has also supplied a thermometer for use in the axilla. The clock-work cylinder can be made to revolve more rapidly than once a day. Of course, the charts here given are reduced in size, the actual dimensions being 12$\frac{1}{2}$ by 8$\frac{1}{2}$ inches. Too great a correspondence between the records of the nurses and of the instrument must not be expected.

RONALD ROSS, C.B., F R C.S. Eng., F.R.S.,
Professor of Tropical Medicine, University of Liverpool.

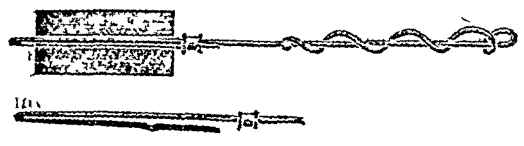
A TRIPLE-WICK CANDLE.

AT a patient's house it is generally difficult, and often impossible, to obtain a suitable light for making observations. This is especially the case when a light for the ophthalmoscope is needed. An ordinary electric lamp simply gives the image of the incandescent wire on the retina unless the lamp glass is ground to a degree that dims the light. A common candle throws only its own small image on the fundus. Every efficient portable electric lamp is heavy and uncertain in its action, and the best lamp of all—a paraffin lamp with a broad wick—is not only cumbersome but soils whatever is near it to a degree that is at last insupportable. A serviceable light I have often obtained by cutting away with a knife one side of two pieces of candle, so as to bring their wicks near enough together for the flames to blend. This suggested the idea of a three-candle wick. After a good many trials the most serviceable is found to be a wax candle, oval in section, 1$\frac{3}{8}$ inches wide, with the three wicks a quarter of an inch apart. The flames of these blend, forming a flat flame $\frac{15}{16}$ths of an inch wide, which is a practically adequate illumination. Experiment shows that the light is steadier and better without any form of chimney or lantern. The oval candle (as supplied) is inclosed in a tin tube of corresponding size and shape, with tubular caps to fit on each end to prevent the tops of the wicks being broken. The "wax" is hard and soon sets after the flame has been blown out or extinguished by the cap The metal casing prevents any "guttering," and the candle when burned down can easily be pushed up from the lower end by the fingers. The dimensions of the outer case are 5 inches long, 1$\frac{1}{2}$ inches wide, and $\frac{7}{8}$ths of an inch thick, a sufficiently small size to prevent consciousness of its presence in the pocket. It is made by Hawksley, 357, Oxford street, London, W. If a condensed light is desired it can be obtained by a lens on a rod hinged to a metal band to slip over the case.

Queen Anne-street, W. W. R. GOWERS, M.D. Lond.

UTERINE "FLAG MOP."

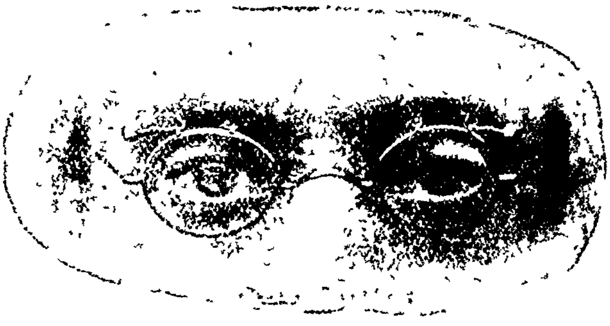
THIS little instrument is designed to serve as a substitute for the instrument known as Playfair's probe and I think will be found convenient for all the cases where that instrument is useful, the great point which always struck me as against the latter being the difficulty of removing the wool after use. In my little instrument it is, at any rate, quite easy to replace the lint, wool, or gauze by a clean piece in a moment; in fact, it is the application of the principle of ordinary sponge-holder to an instrument which is intended to be used in cleaning out or making applications to the interior of cavities for which the ordinary sponge-holder is too bulky. The instrument has been made for me by Messrs Reynolds and Branson of Leeds in aluminium, and either strips of lint or pieces of bandage or ribbon gauze can be used with it very conveniently, and these may be inserted either in the form of a broad strip placed between the serrated portion, so that the metal grips the material like the midrib of a leaf, or by the edge, so as to make a flag. Turning the instrument round in the hand the material is easily rolled around to make a convenient mop, and is equally easily undone and replaced when soiled by use. If it is thought advisable to protect the tip of the instrument (which, however, is blunt), a narrow strip of gauze or lint can be inserted between the serrations near the top, carried over the top, and then wound spirally round as in bandaging a finger, and fastened off where required by the moveable collar, which brings the serrated surfaces together. The instrument is sufficiently rigid for use, but can be bent in easy curves to suit the shape of the uterus or any other cavity; and as there is a little projection at two and a half inches from the point it can be used as an ordinary uterine sound if desired.



Harrogate. E SOLLY, M.B. Lond., F.R C S.Eng.

SPECTACLE FRAMES FOR PTOSIS.

Messrs. W. F. Stanley and Co. of Railway-approach, London-bridge, have sent us a spectacle frame intended for the relief of ptosis without operation. To the upper borders of the lens frames are fitted small spring supports which will obviously keep up the drooping eyelids. We doubt the comfort of the apparatus, but to those persons who dread anything in the way of an operation the spectacles will very possibly appeal. The illustration shows the spectacles in use.



ELEVENTH ANNUAL REPORT (FOR 1902) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

III.[1]

AMONG the official publications of medical officers of health Mr. Shirley Murphy's present report is quite exceptional in this respect, that it contains particulars of the behaviour of chicken-pox in a vast urban community side by side with those of a concurrent epidemic of small-pox. We have previously learnt that in the early days of the recent epidemic the spread of small-pox in London was accelerated by the circumstance that in some cases there had been failure to distinguish between chicken-pox and small-pox. Accordingly the Council, acting on the advice of the medical officer of health, most prudently resolved to require the compulsory notification of chicken pox to the local sanitary authorities of the metropolis under the provisions of the Public Health Act. Although the primary object of this expedient was obviously the arrest of small-pox, it nevertheless incidentally enabled Mr. Shirley Murphy to prepare unique statistics concerning not less than 25,000 cases of varicella, and these he has analysed with every needful detail, not only with regard to the age and sex incidence of the attacks but also with regard to their distribution in relation to locality and to time. It is common knowledge that varicella is but rarely a fatal disease. At any rate, only a few deaths annually have been attributed to this cause in the returns of Somerset House and probably most of these have really been cases of unrecognised small-pox. Considerations of space prevent our following Mr. Shirley Murphy, as we should have liked to do, in his careful and lucid examination of the local incidence of varicella. We would, however, especially direct the attention of the profession to this portion of his report, feeling assured that it will be found interesting and helpful to busy practitioners in their treatment of what is sometimes a very perplexing complication of graver diseases.

---

[1] Nos. I. and II. were published in THE LANCET of Feb. 6th (p. 385 and 13th (p. 456), 1904, respectively.

Measles in 1902 appears to have been somewhat less fatal than usual in London, accounting for the deaths of 51 per 100,000 of the population at all ages, as compared with 58, the average rate in the preceding ten years. In the metropolis it was more fatal in 1902 than in any of the great English towns except Bristol, Bradford, Hull, Salford, and Newcastle. Measles mortality is important mainly in early childhood, for more than nine-tenths of the deaths occur at ages under five years. Above this age the deaths from this disease in London are less than 160 a year on the average. Ignorance among parents concerning the infectiousness of measles and their unwillingness or inability to take the necessary precautions are the chief causes of the almost universal prevalence of the disease; and the fact of its high infectiveness for about three days before the rash militates greatly against the success of public efforts to limit its spread. Varying temporary success has attended the action of local medical officers of health in excluding possibly infective children from school. In spite of every precaution the disease in London recurs with increasing severity every two or three years, attacking the susceptible children who have accumulated in the intervals. "It is not probable," says Mr. Shirley Murphy, "that efforts made to limit the spread of measles will do more than postpone the age of attack, but it may be expected if this result can be attained that the mortality of measles would be diminished." The County Council has, with the consent of the Local Government Board, applied to measles those sections of the Public Health Act which prohibit the exposure of infected persons and things and their transmission from place to place without reasonable precautions and also those sections which provide for the disinfection of houses and clothing and for the disposal of bodies dead of dangerous infectious diseases. The county medical officer suggests the trial, at any rate, of hospital accommodation as a means of checking the present excessive mortality of measles. Pulmonary diseases are well known to be the most frequent and fatal of the complications occurring in measles—complications, moreover, against which the poor have the least adequate means of contending. It is therefore worthy of consideration whether the hospital treatment of measles cases should not be tried, on a limited scale, with a view of testing its value in reducing the fatality of the severer attacks of that disease.

Scarlet fever in London does not appear to have varied greatly, either in prevalence or in fatality, during the last two years. But if the last decade be compared with the first decade included in the table—namely, that terminating with 1868—the mortality to which it gave rise is seen to have decreased enormously. Diagram IX. in the present report shows this clearly. Thus, the mortality in the ten years 1859-68 is shown to have ranged from 10 per cent. below to as much as 235 per cent. above the mean rate for the whole period, whilst in the ten-year period just completed it has fallen from 30 per cent. below to 85 per cent. below the mean. The incidence of reported attacks is well shown in Diagram XI. which gives the relative incidence of scarlet fever cases in each month since 1891, the first year in which notification in London was compulsory. Taking the first quinquennium after this year it is seen that the reported cases were in the proportion of 5·9 per 1000 of the population at all ages, whilst in the more recent quinquennium the proportion fell to 3·8 per 1000. It is further to be noted as a probable factor of this decrease that since 1890 the admissions for scarlet fever to the hospitals of the Metropolitan Asylums Board have steadily increased from 40 per cent. to 78 per cent. of the total cases known to have occurred in the metropolis. In 1902 scarlet fever mortality was lower in London than in any of the great English towns except Leeds, Nottingham, Hull, and Leicester, but it was higher than in any of the chief continental and foreign towns except St. Petersburg, Berlin, Vienna, and New York.

In regard to the preventive efforts of the County Council respecting scarlet fever we notice with regret that although in 1902 that authority sought to obtain parliamentary [illegible] the distribution of infected milk [illegible] the right to require from milk [illegible] omers and information as to the source of their milk, nevertheless, these powers were rejected by Parliament, so that a highly important measure, obviously necessary for the protection of the people of London against infectious disease, is still wanting.

During the last four years there has been in London a steady decline in the fatality of diphtheria as compared with its average in the four years immediately preceding—a decrease represented by a fall in the average death-rate of more than one-third. It is further worthy of note that during the last 12 years there has been also a decline in the case mortality of this disease, the mortality among the notified attacks having fallen from 22·5 per cent. in 1891 to 10 per cent. in 1902. In the year 1902 diphtheria was less fatal in London than in any of the great English towns except Manchester, Birmingham, Leeds, Nottingham, Leicester, and Newcastle-on-Tyne, whilst if the figures are to be trusted it was more fatal in London than in any of the chief foreign and continental towns except Paris, St. Petersburg, Vienna, and New York.

Typhus as an endemic disease has now practically ceased to trouble us in London, although it still continues to "breed true" in parts of Ireland and occasional cases of the disease are from time to time imported thence into certain parts of this country. Not many years ago typhus was, perhaps, next to small-pox, the most dreaded pestilence that infested the slums of our great commercial centres and we well remember the time when it contributed almost as largely as enteric fever to the death toll of the metropolis. But now, happily, this is no longer true; in the year 1902 not a single death was attributed to typhus and the death-rate therefrom in the last ten years has averaged less than 1 per 1,000,000 of the population. The virtual extermination of typhus is doubtless peculiarly gratifying to the county medical officer of health who in past years, both in the fever hospital and in the slums, devoted so much personal attention to the study and prevention of that disease.

Enteric fever has occurred in London during the last two years in the proportion of 70 per 100,000 of the population. If the period since 1869 be divided into two portions it will be seen by Diagram XVII. that in the first half of that period—viz., from 1869 to 1884—the death-rate from that disease was almost constantly above the mean for the whole period, whilst since 1884 it has been as constantly below it. A careful study of this chart will show this clearly. What is peculiar in the history of enteric fever in 1902 is the fact of its abnormal distribution with respect to time. Thus Diagram XVIII. shows that whilst the duration of excessive enteric fever prevalence extends normally from the thirty-fourth to the fifty-first week of the year, in 1902 that period began as early as the twenty-fifth week, exceptional prevalence being noted in the twenty-ninth and thirtieth weeks of that year. This increase was not limited to any one locality but was widely distributed throughout London. In discussing the causes of enteric fever in London the subject most frequently referred to by local medical officers of health is that of infection from the consumption of shell-fish. Large quantities of such food, especially cockles, came to London from the neighbourhood of Southend and many London inhabitants visited that resort during the summer months, some for a single day and others for longer periods, many of them partaking of shell fish during their stay. "There is no reason for doubting," says Mr. Shirley Murphy, "that many cases of enteric fever in London were caused in this way, and it is highly probable that the consumption of shell fish from other places had a similar result."

In view of the foregoing experience it is satisfactory to note that the County Council has memorialised the Local Government Board, expressing the Council's hope that, in the interests of the public health, the Board will as soon as possible take steps to amend the law so as to prohibit the laying down of shell-fish in sewage-polluted creeks, &c., and to prohibit the sale of such shell-fish for human consumption; it also asks that all unpolluted layings, fattening beds, and storage ponds at present in use may be protected from pollution by any person or any sanitary authority. As this subject is now under consideration by the Royal Commission on Sewage Disposal we may hope that suitable legislative measures will be adopted by the Government for the protection of an important source of food supply.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 27, 1904.

War Office Changes.

As our readers, in common with the rest of the world, are aware a great scheme of army reform is in process of being carried out. Sweeping changes have been recently introduced and many are still impending in the organisation of the army, in the remodelling of the War Office, and in the readjustment of its machinery. It is a matter of vital importance that what is now being done should, to every possible extent, meet all present and future requirements and should have some guarantee of permanence about it. We wish that we could predict that such is likely to be the case, so far as the efficiency of the medical service and the medical and sanitary needs of the army are concerned; but, on the contrary, we cannot help feeling that the country is threatened with a distinctly retrograde movement by which constantly recurring evils and causes of public complaint are more likely to become stereotyped than removed. It will be intolerable if no well-grounded attempt is now made to obviate the scandals which, whether real or only alleged, have arisen out of so many of our wars from the time of the Crimea (when army sanitation was comparatively unknown) up to the date of the recent protracted struggle in South Africa. The facts connected with the late war are still fresh in the public mind, while the allegations made regarding the medical service in the Egyptian expedition of 1882, which on full official inquiry were shown to have been either unfounded or exaggerated, have not yet passed into oblivion. It will be remembered that as the result of the recent reforms in the Army Medical Service, which were mainly attributable to the South African war, we were able to congratulate the army and the medical profession on the improvements and changes that had taken place in the Medical Department. The influential official position which the head of the Army Medical Service as the representative of that service was for the first time to hold in connexion with the Government, the War Office, and the military authorities we regarded as a very notable feature. Quite recently, however, in announcing the names of the members of the newly constituted Army Council[1] we had to allude to the fact that the head of the Army Medical Service had no place on that council; and we would refer our readers to our remarks on the subject. We repeat what we there said that it is, in our opinion, absolutely essential in the interests of the army that the medical service should be represented adequately and prominently in the councils of the War Office. We are therefore glad to see that the British Medical Association has brought the subject to the notice of the Secretary of State for War who will assuredly have to declare his intentions and to justify them to the satisfaction of the House of Commons. It is not a question of mere medical sentiment or military detail; it is a matter of national interest that the medical service should not be relegated to some indirect and subordinate position but should occupy a place worthy of its grave and important responsibilities, such as Mr. BRODRICK rightly gave to it. The difficulties with which the Army Medical Service has always had to contend have largely arisen from the fact that responsibility and power have hitherto borne no relation to one another among the heads of the department. The late War Minister made a real attempt to rectify this unfortunate position by putting the head of the Army Medical Service in a situation at the War Office, where he could make the wants of his service directly known to those who could supply them. And now Mr. ARNOLD-FORSTER proposes to undo the work of his immediate predecessor in office in order to return to an obsolete state of things which has not stood the test of experience but has been already tried and discarded because found wanting. With the results and findings embodied in the report of the Royal Commission on the War in South Africa and the report on the Care and Treatment of the Sick and Wounded in the South African Campaign still fresh in our memories we cannot shut our eyes to the evils of unpreparedness with regard to medical and sanitary matters in war. But that is what Mr. ARNOLD-FORSTER will risk for the country.

◆

The After-Care Association.

THE After-Care Association, as is now well known, is a body which devotes itself to the well-being of poor persons discharged recovered from asylums for the insane and it had the good fortune to hold its annual meeting on Feb. 11th under the chairmanship and hospitality of the Bishop of LONDON who is one of the vice-presidents. His Lordship, in his opening remarks, said truly that the work of such an association appealed more or less directly to every member of the community as it was impossible to avoid some personal knowledge of the distressing effects produced by disease and derangement of the mind upon acquaintances, friends, or relatives.

The chief objects of the association are to facilitate the readmission of poor persons, who have been discharged as recovered from asylums, into social life: (1) by obtaining for them when needful an interval of change of scene and air, often so beneficial on recovery from ordinary sickness, by boarding them out in the country in cottages under proper care and supervision; (2) by giving them grants of money and clothing; and (3) by assisting them to obtain suitable employment. Surely no philanthropic scheme could be more worthy or more commendable and the council of the association is able to state in its annual report for 1903 that the work of the year has again been very encouraging and that the proportion of cases successfully started in life has increased, while the accounts which have been received of those helped in past years are satisfactory. The report goes on to say that during the year 250 cases had been before the council; of these, 155 were women and 95 were men. All cases, we are told, are thoroughly investigated by the officers of the association previously to being brought before the council and, where possible, all employers are interviewed. Sometimes as many as 20 or more visits have been made by a member of the staff in connexion with a single case. This means a very considerable expenditure of time and money but the council "has been well repaid for this work by the most satisfactory manner in which a very large majority have retained the situations found for them." To carry out this work the total amount of subscriptions, donations, and contributions for maintenance for the year came to £648. If we take the figures roughly as an estimate of income and work done it means on the average an expenditure of 50*s.* for each case which came up for consideration and which, if not actually maintained for a period or assisted pecuniarily in some way, had to be investigated as to its merits and circumstances. Considering the number and variety of claims upon the finances of the association it appears to us that this expenditure is not only moderate in itself but is also a testimony to the importance and significance of the services, gratuitous and otherwise, of the members of the council and their fellow workers. But bearing in mind the fact that the association has been in existence for some 20 years or more we are bound to say that, in our opinion, this income, which is necessarily the measure of the association's capacity for carrying out its beneficent work, is far from being commensurate either with the requirements of the class of "poor persons" under consideration or with a reasonable manifestation of philanthropy on the part of a responsible public community.

---

[1] Vide THE LANCET, Feb. 13th, p. 462, and Feb. 20th, p. 538.

A glance at the last report of the Commissioners in Lunacy shows that on Jan. 1st, 1903, the pauper insane, or, as some prefer it, the rate-supported insane, in England and Wales numbered 103,794 and we are certainly not overstating the case if we say that 6000 or 7000 patients of this class are discharged as "recovered" every year. But of the number thus discharged as no longer requiring the immediate care and supervision of an asylum, how many are so far recovered as to be able at once to cope successfully with the buffetings and storm and stress of social and domestic life and to obtain suitable employment? In the absence of statistics on the point we may, at all events, reckon that at least one-half need the temporary help of an organisation like the After-Care Association if the best opportunities are to be secured to them of remaining well, of acquiring increased mental stability and confidence, and of warding off the risks of relapse. The 250 cases which, as we have said, came before the council during 1903 represent less than one-tenth of the work which the association, if it had the means, would be able to carry out. In other words, the After-Care Association ought to be placed in such a position financially as to enable it year by year to lend a helping hand to 2500 poor persons discharged recovered from lunatic asylums. This is the lowest estimate possible of the number of persons requiring such services as the association offers. The feeling expressed at the largely attended annual meeting at London House was strongly in favour of strenuous efforts for making the association and its work more widely known to the public and thereby increasing the number of members and workers as well as of private benefactors and subscribers. The development of self-supporting provincial branches to work locally in connexion with the parent association is necessary, while it is proposed to endeavour to obtain grants from public funds. There is every reason why public funds should contribute to the advancement of this particular sort of work, for, apart from physiological and hygienic considerations, it must not be forgotten that the present congested condition of our county and borough asylums necessitates or brings about in many cases a somewhat premature discharge on recovery, thereby handicapping the individuals so discharged in their struggle for existence and leading to an increase in the number of relapses and re-admissions. In this relation it is interesting to learn from Sir JOHN BATTY TUKE, M.P., who seconded the adoption of the report, that he intends at an early date to ask Parliament for the appointment of a commission of inquiry into the lunacy administration of the country with a view to strengthen the hands of the officials in dealing with what he regards as the two blots of that administration—namely, the defective arrangements as to the early care and management of incipient cases of insanity and the want of provision for the proper after-care of persons discharged recovered from asylums.

The patroness of the association is H.R.H. Princess CHRISTIAN and the Earl of MEATH is the president. The Archbishop of CANTERBURY and the Archbishop of YORK are among its vice-presidents and practical support and personal encouragement are given to its work by the Commissioners in Lunacy and many other official and private workers of standing and experience in the lunacy world. The offices of the association are at Church House, Dean's-yard, Westminster, and Mr. H. THORNHILL ROXBY is the secretary. There is no other society of the kind in the United Kingdom and, as we have endeavoured to point out, its objects are both extensive and urgent and fully deserving of the practical benevolence of the charitably disposed public.

◆

The Sale of Poisons.

SEVERAL recent occurrences are likely to cause anxious inquiries whether any steps can be taken to check the self-administration of poison under conditions of despair and it is highly probable that the matter is one which will in some form be brought under the attention of the Government at an early date. Notwithstanding the thoughtful care which resulted in the construction of the Act which regulates the sale of poisons by chemists and druggists there can be no doubt that at the present time there are abundant facilities for the acquisition and employment of large quantities of poisonous substances. Numerous attempts have been made to introduce and to enforce restrictions which would impede the purchase of poisons for unlawful purposes. The general desire has been to afford protection against homicide and the precautions which have been suggested and acted upon tend to facilitate legal investigations by supplying records of the sale of poisons to individuals who can readily be traced. The various steps which have been taken in the interest of public welfare are instructive, since they demonstrate the ardent desire to exert control, and they also show that this desire has been hampered and rendered ineffective by a respect for vested interests and by the frequency with which poisonous substances are largely employed for legitimate purposes. In 1868 an Act to regulate the sale of poisons and to alter and to amend the Pharmacy Act of 1852 gave the Pharmaceutical Society the power to draft regulations for keeping, dispensing, and selling certain poisons which were enumerated in a schedule. It was further declared to "be unlawful for any person to sell or to keep open shop for retailing, dispensing, or compounding poisons unless such person shall be a pharmaceutical chemist or a chemist and druggist within the meaning of the Act." A little later in the Act came the list of exceptions which has done so much harm indirectly by facilitating the sale of poisons. Clause xvi. states that "nothing hereinbefore contained shall extend to or interfere with the business of any legally qualified apothecary or of any Member of the Royal College of Veterinary Surgeons of Great Britain, nor with the making or dealing in patent medicines, nor with the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing." This clause is probably to blame for many of the "accidents" which occur. Many examples could be quoted of poisons which have been procured under the plea of a desire to destroy animals. Our coroners' courts also afford frequent evidence of the dangers resulting from patent medicines which constitute a grave source of risk when improperly employed through ignorance or design. Many of these must be labeled "poison" on account of the presence of opium or of one of its active ingredients but this label does not check the sale of various nostrums which are largely advertised by leaflets and in the daily press.

The schedules drafted in 1868 have from time to time been extended to include additional drugs and preparations; sometimes these seemed to be necessitated by the introduction of new drugs and occasionally perhaps by some recent event attracting attention to an oversight. The last important addition was the inclusion in 1900 of "liquid preparations of carbolic acid and its homologues containing more than 3 per cent. of those substances" amongst the list of poisons within the meaning of the Pharmacy Act, 1868. When sold for all ordinary purposes these preparations must now bear the name of the article, the word "Poison," and the name and address of the seller. Lest these restrictions should hinder the use of these substances, exemptions are granted for "any preparation prepared for use as sheep-wash, or for any other purpose in connexion with agriculture or horticulture, and contained in a closed vessel, distinctly labeled with the word 'Poisonous,' the name and address of the seller, and a notice of the agricultural or horticultural purpose for which the preparation has been prepared." In spite of precautions carbolic acid still has to be credited with being the poison most commonly employed with suicidal intent and in addition with the responsibility of a relatively large number of accidental deaths. Classified lists of cases of poisoning afford very curious reading since they show that there is usually a reckless disregard for a period of intense suffering or an ignorance of the amount of pain likely to ensue. The poisons most commonly used are carbolic acid, spirit of salts, and oxalic acid, and they are probably selected because they are readily at hand, having been legitimately purchased some time previously for necessary work. The great difficulty which hinders any effective legislation lies in the frequency with which poisons are necessarily used for various purposes in the arts and in commerce. Every photographer and every entomologist is probably in possession of an abundance of poison and in the engrossing preoccupation demanded by his work it may well be doubted whether care is always taken to surround these substances with the vigilant precautions necessary to prevent abstraction for improper purposes.

We need not refer in detail to the statutory requirements connected with the dispensing and retailing of poisons. The regulations have been carefully constructed and generally they afford adequate protection against improper purchase of poison, although they can be evaded by false declaration of the "purpose for which it is stated to be required." All such provisions can be set at naught by the purchase of proprietary preparations or of compressed drugs intended to procure sleep or by the acquisition of small quantities of sedatives procured from several establishments. This last method is often facilitated by the possession of an old prescription and by the absence of a record, stamped upon it, of the dates upon which it has been compounded. This small precaution might prevent many regrettable incidents and it would appear to involve less trouble than the insertion of the lengthy index reference to the druggist's book in which a copy of the prescription will be found duly dated and numbered. In spite of all attempts to surround the sale of poisons with regulations designed to check their purchase with homicidal or suicidal intent the legitimate use of poisons appears to be so widespread that the framing of further restrictions is attended with very great difficulty.

◆

A Chemical Conception of the Ether.

Two distinct schools of thought in regard to the nature of the ether would appear to have arisen out of the discovery of radium in particular and of radio-activity in general. That there is a certain amount of antagonism between the views respectively held is natural enough but we should not be surprised if subsequent developments showed that a compromise will ensue and that time will prove that both schools are, after all, increasing our chances of arriving at a solution of the mystery. We still have amongst us the adherents of the emission theory of light as opposed to the wave theory, and, indeed, the ranks of the former have been decidedly strengthened since the discovery of radio-activity. What may be considered as the orthodox view of radio-activity is that which seeks explanation in the subdivision of the atom into infinitely smaller particles, the electrons. This conception of the atom that it is composed of a cluster has become so clear in the minds of many that already the phenomena of a screen fluorescing under the action of radium is spoken of as a bombardment of electrons. The atom of radium is, so to speak, in a state of disruption, its electrons are projected with enormous velocity, giving rise to the phenomena of light and heat. What Sir WILLIAM CROOKES described some years ago as radiant matter or a fourth state of matter is now made more intelligible, according to one school, by the electron theory and since the electron is the embodiment of an electric discharge we would appear to be in the presence of a phenomenon at one time manifesting itself as matter and at another as force. Thus the borderland between matter and energy would seem to have been broken down. The theory of electrons amounts to a return to the emission theory, which disregards the notion of the transmission of luminous vibrations through an etherial medium. The origin of the emanations of radium is still a mystery, but we may here recall the view that this display of energy is due to the power which radium has of absorbing unknown energies in space and yielding them again in a form within human perception. This is the wave theory as opposed to the emission or electron theory of radium's activity. The wave theory does not necessarily depend upon the assumption that ether consists merely of a subtle highly elastic fluid or medium capable of transmitting vibrations with an enormous velocity. On the contrary, attempts have already been made to found a chemical theory of ether and in this direction the conceptions of MENDELÉEFF, the great Russian chemist who was the first to perceive the beauty, order, and importance of the periodic law of the chemical elements, are of the highest interest.

In a masterly essay recently published[1] upon the subject MENDELÉEFF suggests that the ether is a gas which, like helion or argon, is incapable of chemical combination. The recognition of the ether as a gas assumes, of course, that it belongs to the category of the ordinary physical states of matter, gaseous, liquid, and solid. "It does not require," he says, "the recognition of a peculiar fourth state of matter beyond the human understanding (CROOKES)" and "all mystical spiritual ideas about ether disappear." MENDELÉEFF thus clearly takes the realistic view and it is not to be expected that his attitude would be without the support of well-ascertained facts. His reasoning on the face of it is most cogent. He recognises, in spite of the enormous penetrative power of ether which enables it to pass through every envelope, that it would be impossible to determine experimentally its mass in a given amount of other substances; therefore he speaks not of the imponderability of ether but of the impossibility of weighing it. In short, his propositions are: (1) that the ether is the lightest ultimate gas and is endowed with a high penetrating power which signifies that its particles have, relatively to other gases, small weight and extremely high velocity; and (2) that ether is a simple body or element incapable of entering into combination or reaction with other elements or compounds although capable of penetrating their substance, just as helion, argon, and their analogues are soluble in water and other liquids. He even proposes to place ether as an element in the periodic system at the top of the series of elements known as the zero group which comprises helion, neon, krypton, and zenon. The existence of elements lighter than hydrogen is highly probable because the hydrogen group is preceded by the zero group containing elements of less atomic weight according to the classification. On abundant reasoning MENDELÉEFF gives the first element in his series as "x," the second as "y" to the discovery of which he now looks forward, and the third element in the group is helion. He then clearly anticipates what would be the atomic weight, density, and properties of "x" and "y." He assigns to "x," the ether, an atomic weight of nearly one millionth that of hydrogen, travelling at a velocity of about 2250 kilometres per second. He thus regards ether as the lightest of all the elements both in density and atomic weight, as the most mobile gas, as the element least prone to enter into combination with other atoms, and as an all-permeating and penetrating substance.

Bearing these properties in mind uranium, thorium, and radium (the elements possessing the highest atomic weights) may be looked upon, according to MENDELÉEFF, as suns "endowed with the highest degree of that individualised attractive capacity, a mean between gravity and chemical affinity, which is seen in the absorption of gases and in the phenomena of solution." According to this conception the substance of the ether or gas must naturally accumulate from all parts of the universe towards the medium or mass of the sun just as the gases of the atmosphere accumulate in a drop of water. And the lightest of gases "x" will also accumulate about the heaviest atoms of uranium and thorium and radium and perhaps change its form of motion like a gas dissolved in a liquid. If, however, such a special accumulation of ether atoms about the molecules of uranium and thorium be admissible it seems to us that these elements ought to exhibit radio-activity to the same degree, whereas radium is several thousand times more active than is thorium or uranium, though its atomic weight is not very different. The well-known experiment which shows how readily the emanations from radium affect substances as soon as its salt is placed in communication with them appeals to MENDELÉEFF as "an emissive flow of something material from the radio-active substance and in a sense seems comprehensible if we assume that a peculiar rarefied ether gas capable of exciting luminous vibrations enters and passes off from the radio-active substance." The equilibrium of the ether atoms, it is suggested, may be destroyed in the case of the radio-active bodies by the "massiveness" of the atoms of uranium and thorium, "just as the luminosity of the sun may be, I think, due to its great mass being able to accumulate ether in far larger quantities than the planets." We fail to see how "massiveness" can be a factor in the way described, since the degree of radio-activity of these three elements differs enormously. In further support of his chemical conception of the ether MENDELÉEFF places a remarkable interpretation upon the phenomena proceeding at excessively low temperatures, at which the phosphorescence of many substances, and especially of paraffin, becomes more intense at the temperature of liquid air. His explanation is that paraffin and such like substances have a great capacity for condensing the atoms of ether at very low temperatures—in other words, the solubility or absorption of the ether in some bodies increases in extreme cold. According to this view phosphorescence in these circumstances becomes more intense, for the vibrations of light are then set up in the phosphorescent substances, not only by their own atoms but also by the atoms of ether which condense in th[illegible] bodies and start a rapid state of interchange with the surrounding medium.

---

[1] A Chemical Conception of the Ether. By Professor D. Mendeléeff. London: Longmans, Green, and Co. 1904.

To sum up, it is clear that MENDELÉEFF adopts a distinctly realistic and charmingly simple view of the ether and we cannot but admire the ingenuity with which this great master of chemical science has marshalled so many facts in favour of his conceptions. All scientific men will listen with the greatest respect to the teaching of the elaborator of the periodic law, though they may not agree with him, that ether is a highly penetrative and an elastic gas, a real chemical entity which is at the bottom of the marvellous phenomenon of radio-activity. It is a bold thing to maintain against a powerful school containing men such as CROOKES, RAMSAY, LODGE, LOCKYER, SODDY, and RUTHERFORD that any conception of the division of the atoms into electrons is contrary to the scientific teaching of the present day. Yet that is what MENDELÉEFF confesses to be his attitude until "some one demonstrates either the actual transformation of ordinary matter into ether, or the reverse, or else the transformation of one element into another." It will be interesting to see, now that helion has been shown to appear as a product of radio-activity and of the slow breaking down of radium, how far the eminent Russian philosopher will consider it expedient to modify his tenets.

Annotations.

"Ne quid nimis."

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

WE published in our issue of Feb. 6th, p. 377, a brief account of this association which has now got seriously to work. In view of the approaching London County Council elections on March 5th all medical men whose work lies in the metropolis are invited to send in their names as soon as possible to the honorary secretary of the association, Dr. Arthur W. James, 69, Gloucester-terrace, Hyde Park, W. In this way candidates for municipal honours may see that the medical profession in London is of one mind as regards the necessity of the Council providing an efficient street ambulance service for London. Medical men joining the association will find themselves in good professional company. Several hundred members have already been enrolled, amongst them being the President and many of the Council of the Royal College of Physicians of London; the President, an Ex-President, two Vice-Presidents, and 16 members of the Council of the Royal College of Surgeons of England; the Vice-Chancellor of the University of London, and members of the staffs of all the London hospitals, among whom may be mentioned Sir Thomas Barlow, Sir T. Lauder Brunton, Sir William H. Bennett, Sir Alfred Cooper, Sir Anderson Critchett, Sir R. Douglas Powell, Sir E. Cooper Perry, and Sir Thomas Smith. The Metropolitan Street Ambulance Association has already sent a communication on this subject to every county council candidate, inclosing a postcard for a reply to the following question: "If elected to the London County Council will you interest yourself in securing the establishment by the Council of an efficient street ambulance service for London?" A great many satisfactory answers have been received and it appears certain that candidates will do what is wanted if the medical profession will point out to them the urgency of the matter. Neither those responsible for the local government of the metropolis nor the London public understand that our enormous capital has virtually no ambulance provision whatever. There are certain ambulances generously placed by Mr. H. L. Bischoffsheim at the public disposal, the police have a few stretchers, and the St. John Ambulance Association a few litters at its stations; but considering the population concerned there is virtually no provision in London for the rapid and safe conveyance of the victims of street accidents to the hospitals. The chances that a man with, say, a broken leg will reach a hospital in grievous anguish and at considerable risk of increased damage in a four-wheeled cab are very great, and this example alone is sufficient to bring before medical men the importance of a systematised scheme for supplying London with ambulances. We advise our readers to follow the example of the presidents of the Royal Colleges and other prominent members of the medical profession and to join the Metropolitan Street Ambulance Association.

THE VENTILATION OF RAILWAY TUNNELS.

A SERIES of articles on the advantages of the Saccardo system of ventilating railway tunnels has recently appeared in successive numbers of the *Engineer*, commencing with that of Jan. 15th. The difficulties presented by atmospheric vitiation in tunnels are exemplified by the conditions which accompanied increase of traffic in that of the St. Gothard. The difference of ordinary atmospheric pressure prevailing at opposite extremities of this tunnel usually suffices to create a decided natural draught throughout its length and for the first one and a half years during which the trains were run it was supposed that natural ventilation would be sufficient. Even when it had been for nearly eight years open for traffic—namely, in March, 1889—the chief engineer stated in a report that there existed at all times a natural air current so that, although the tunnel employés and trainmen were affected by the smoke, the vitiation of the air did not prevent them from working. At that time there were about 42 trains a day but when more trains were put on the air became worse. In the summer of 1897 there were 61 trains a day. Moreover, from the middle of September, 1897, up to the end of the year the atmospheric pressure at both ends of the tunnel was so nearly alike that the smoke from the locomotives simply remained in the tunnel without escaping by either entrance owing to the feebleness of the natural ventilation. The atmosphere then became injurious to the tunnel employés and the number of trains had to be reduced till the air was rendered just tolerable. The trainmen also were inconvenienced by the fumes, although their suffocation never went to the stage of syncope, as had often happened before—and has happened since—in tunnels of very much shorter length but constructed on steeper gradients, wherein doubling and trebling of the locomotives are necessary. Various schemes were now proposed to prevent the loss of traffic caused by the enforced diminution of trains, but nothing was done until in April, 1898, the directors determined to adopt the Saccardo system of forced ventilation which had since July, 1894, been employed with fair success on a main line of the Italian Adriatic Railways in the Apennine tunnel near Pracchia This method of mechanical ventilation, invented by Marco Saccardo, is in principle very simple. A cone-shaped ring of sheet iron, large enough for the trains to pass through but of less diameter than the tunnel, is placed concentrically with the latter and the vacant space between them is closed at the end next the mouth of the tunnel but remains open at the further end. Two air channels leading from this interspace communicate with two fans or ventilators by means of which air can be either forced into the tunnel or withdrawn from it. The length of the tunnel from the Swiss or north end at Göschenen to the Italian or south end at Airolo is 15 kilometres or about nine miles. The prevailing direction of the natural air current is from north to south and as it is generally preferable to create a current from the ventilator rather than towards it the ventilating station has been placed at Göschenen. It was stipulated by the railway company that the air throughout the whole length of the tunnel should have a uniform velocity of three metres (9 feet 10 inches) per second and no more. The ventilators have been working regularly since March, 1899. The effect was satisfactory from the very first, the smoke never accumulates with such density as previously, the nauseating mildewy odour which was formerly prevalent has disappeared, and the suitability of the air for breathing is, of course, immensely improved. Among other tunnels satisfactorily ventilated in the same manner and described in the *Engineer* mention may be made of the Ronco tunnel *(5·2 miles in length) and the Giovi tunnel (two miles in* length), both of which are not far from Genoa. The principal reason which led to the application of forced ventilation in the Giovi tunnel was the asphyxiatio [illegible] on August 12th, 1898, of two enginemen; the train th[illegible]n back down the hill to a spot in the Polcevera valley where a marble cross now marks the site of a terrible accident. The Saccardo system of ventilation is also to be applied to the Mont Cenis tunnel. The station containing the machinery is near the Italian or Bardonnecchia entrance and was completed towards the close of 1903.

BRANDY v. BRITISH BRANDY IN SCOTLAND.

IN THE LANCET of Feb. 13th, p. 447, we commented upon a conviction under the Sale of Food and Drugs Act at Accrington, where some innkeepers had sold "British brandy" when asked for brandy. The medical officer of health of the county of Lanark, Dr. J. T. Wilson, has recently succeeded not only in obtaining convictions before the sheriff substitute for similar offences but in a case selected as a test case for appeal to the High Court at Edinburgh has had the satisfaction of hearing upheld by the court his contention as to the application of Section 6 of the Sale of Food and Drugs Act, 1875, to grain spirit sold as brandy. The facts of the case in which the appeal was made seem to us to have established the culpable conduct of the defendant rather more clearly than is usual upon such occasions, although the circumstance which causes us to say *so apparently affected the opinion of the Lord Justice* Clerk in exactly the opposite manner. The inspector who bought the bottle of spirit which formed the subject of the charge asked the vendor what kind of brandy he was selling and received the answer, "Tricoche's brandy," which he imperfectly heard. He went away and returning ten minutes later asked a shopman in the defendant's employment for "a bottle of brandy," when he was given a bottle bearing the label "Old Brandy, Tricoche & Co., Cognac ***," for which he had to pay 8*s* The finding of the sheriff-substitute as to the liquor thus sold, upon the evidence of analysis laid before him, was that it "contained a large proportion (about one-half) of either raw grain or beet-root spirit and was therefore not of the nature, substance, and quality of brandy." The decision of the Court of Appeal upon this and upon the other facts found by the sheriff-substitute was that they constituted an offence against the Sale of Food and Drugs Act. With regard to one of the objections raised, "that the complaint was not relevant in respect that it did not state what genuine brandy is," Lord Moncrieff said: "It is complained that the sheriff-substitute has made a standard for brandy for himself. I do not see how he could avoid that. He has taken the evidence of skilled witnesses and has come to a conclusion. *It may* be wrong but we must take it as a matter of fact"—in which view the rest of the court concurred. The point which caused some doubt in the mind of Lord Trayner, the third judge, and in consequence of which the Lord Justice Clerk declined to concur in the judgment of his learned brethren as to the guilt of the defendant, arose out of the question and answer referred to above which preceded the sale of the "brandy." These were considered by his lordship to show that "the inspector was told what kind of brandy was being sold," so that, even though he might not have heard or understood what was said, "the seller was entitled to assume that the purchaser was aware of what he was getting" We do not consider that everyone who buys brandy, whether an inspector under the Sale of Food and Drugs Act or not, is to be expected to know the reputation of Messrs. "Tricoche and Co." or from what materials they distil their stuff. To us the sale of a bottle labeled "Old Brandy, Tricoche and Co., Cognac ***," at 8*s*. implies the offer and acceptance of a French brandy from the Cognac district, an old and consequently matured spirit of "three star" quality, at a price which entitles the purchaser reasonably to expect an article such as the label describes. In short, the transaction strikes us as a worse instance of sale "to the prejudice of the purchaser" than where "British brandy" is sold as "brandy" without the additional attractions of deceptive French names, a claim of age, and an absurd price. The liquid sold at 8*s*. in Lanarkshire had apparently been imported from France and bought in cask from the importers by the retailers who had bottled it, and we feel inquisitive as to what it may have cost them before they put it on the market, a matter which was, no doubt, irrelevant to the appeal but which in such cases might, we conceive, *affect the penalty inflicted*. In any case, however, whether the defendants were themselves deceived or not, we congratulate the medical officer of health and the county council of Lanark upon their success on behalf of the public, and especially because in Scotland even more than in England brandy is not a beverage but is used principally for medicinal purposes. We venture to think that recent successful prosecutions in England and in Scotland have been results of THE LANCET Special Analytical Commission on Brandy. The Commission sought to make it plain, among other matters, that brandy, if genuine, is a distillation of wine or a "grape spirit" and that fraudulent imitations can be surely detected by chemical analysis. These propositions have now been proved by evidence *in courts of summary jurisdiction and a* court of appeal has decided that the facts thus established constitute an offence against a useful Act of Parliament passed for the protection of the public.

MYOSITIS OF THE RECTUS ABDOMINIS AFTER TYPHOID FEVER.

MYOSITIS is a rare complication or sequel of typhoid fever. In a series of 829 cases Professor Osler found it only once. In the *Boston Medical and Surgical Journal* of Nov 26th last Dr. D Scannell has described a case in which the rectus abdominis muscle was affected. It is of interest both because of the difficulty of diagnosis and because no other case in which this muscle was affected appears to have been recorded. A boy, aged nine years, was admitted to hospital with a severe attack of typhoid fever. After four weeks furunculosis, mainly of the abdomen, thighs, and buttocks, appeared as a complication. Cultures yielded staphylococcus pyogenes aureus and streptococcus pyogenes. 12 days later signs of ischio-rectal abscess developed. The pus did not yield the typhoid bacillus. Two months after admission he was discharged well. Five days later he was taken back with the history that on the day after discharge there was profuse diarrhœa with a little blood in the stools and abdominal pain. The pain increased and there were chills and fever. On re-admission the temperature was 100·2° F. and the pulse was 134. He lay in the dorsal decubitus position with the thighs flexed. The lower abdomen on the right side was dull and very tender and a mass was felt there, [illegible] like that conveyed by a full bladder. The Widal reaction was negative. Acute perforative appendicitis with abscess was diagnosed. Under ether, the abdominal muscles being relaxed, the question of a full bladder again presented itself but catheterism negatived this supposition. An incision was made over McBurney's point. The peritoneum and appendix were found to be normal. There was an ovoid indurated thickening of the right rectus muscle in its lower third. The appendix was removed and the wound was closed. Unfortunately the swelling was not incised. On the sixth day after operation the wound was healing and the temperature had fallen to normal but the induration and tenderness persisted. On the tenth day after operation the induration was slightly diminished and the wound was healed. From the thirteenth to the sixteenth day the conditions present on readmission—pyrexia, pain, spasm, and palpable mass—were reproduced. Then the mass gradually diminished and 24 days after operation it had completely disappeared.

A CRITICAL TRIAL OF SOME NEW DRUGS.

IN the *Wiener Klinische Rundschau*, No. 50, 1903, Dr. Alois Strass of Vienna gives the results of a careful critical examination of the effects of some drugs of comparatively recent introduction—viz., aristochin, aspirin, hedonal, mesotan, and theocin—with a view to determine their usefulness. Aristochin, a neutral carbonic acid ester of quinine, was administered in doses of from a quarter to half a gramme in place of quinine itself in about 15 cases. It has been claimed for this substance that it does not cause the noises in the ears and the giddiness sometimes resulting from the use of the sulphate of quinine and that it is not bitter. Dr. Strass was satisfied of the usefulness of aristochin but was not convinced in many cases of the absence of symptoms of cinchonism after its use and came to the conclusion that it had no advantages over the sulphate, except that for children the absence of the bitter taste was an advantage. Aspirin, which is a derivative of salicylic acid, one atom of hydrogen being replaced by an acetyl group, was given in about 40 cases. Satisfactory results were only obtained in cases with a rheumatic origin. Its action was in no way inferior to that of sodium salicylate and the unpleasant effects of this substance were in general not forthcoming. Aspirin entirely failed to influence the fever of pulmonary tuberculosis but was useful in some febrile conditions of doubtful origin and in the fever of acute gastro-enteritis. Hedonal, a hypnotic of the urethane group, was administered to about 40 patients, mostly cases of heart and lung disease with a few cases of neurasthenia and neuritis. The usual dose was from 1 to 1·5 grammes. Dr. Strass found that this drug had very little influence on insomnia, unless it were combined with some other drug influencing the cause of the sleeplessness more directly; for example, in heart cases it was necessary to give some strophanthus, in pulmonary tuberculosis codeine, and in neurasthenia bromides. In cases of neuritis and chronic alcoholism it tended to produce cerebral congestion and some excitement and was soon refused by the patients. Mesotan, a metoxymethyl ester of salicylic acid, was tried in about 30 cases and was found to be very useful in all conditions in which salicylates are of value. Its local action could be increased by the production of a local hyperæmia before its use by means of baths or dry cups—e.g., in sciatica and lumbago. Mesotan was, moreover, found to be a useful [illegible] with good results [illegible] from eight to 14 days [illegible] were rubbed into the skin [illegible] and [illegible]. Theocin ([illegible]), a synthetically prepared xanthine derivative, was tried in about 30 cases. It proved to be a valuable [illegible] cases but only when no heart failure and no lowering of the blood pressure were present.

THE RELATION OF THE "N" RAYS TO VISION.

A NEW department of physiology seems likely to be opened up through the discovery of Blondlot's "n" rays which appear to play an important rôle in regard to various manifestations of vital activity. Several scientific observers have been working at the relation of the "n" rays to vision and Blondlot has observed that the eye is itself a source of the rays and also that the sensitiveness of this organ to light is augmented under their influence. M. Augustin Charpentier has carried the investigation a step further and has tried the effect of directing the rays upon the brain through the skull. Stimulation in this way, especially of the region of the angular gyrus, produces a sensation of luminosity. Changes in the pupils can also be brought about by introducing the region of the corpora quadrigemina into the path of the rays or by acting upon the medulla through the agency of a source of the "n" rays placed over the cervical spine. It is probable, therefore, that the "n" rays which accompany ordinary light waves are in part responsible for the phenomena of vision and in a recent communication to the Société de Biologie M. Bohn has ingeniously applied this hypothesis to explain why fresh water and marine animals adhere to their respective habitats. In some experiments on Nereis he found that while the animal when kept in sea water swims about actively in the light, in darkness it falls to the bottom of the vessel and crawls there sluggishly. A similar change takes place when Nereis passes from salt water to fresh—e.g., as in entering the mouth of a stream—its activity ceases and it is then carried out to sea again. M. Bohn suggests that the relatively dormant condition has the same essential origin in the two cases and is to be attributed to the cutting off of the "n" rays, on the one hand by removal of the source of light and on the other through the inability of the rays to pass through fresh water.

THE ASSOCIATION FOR THE TRAINING AND SUPPLY OF MIDWIVES.

THE council of the Association for the Training and Supply of Midwives is issuing an appeal for funds to enable it to carry on and to extend the work of the association. As it points out, the new Midwives Act requires that in future all midwives shall be trained and registered. After March, 1905, no one will be able to take the title of midwife unless certificated and after 1910 no women will be allowed "habitually and for gain to attend women in childbirth" without the certificate of the Central Midwives Board. There can be no question but that the number of untrained women who are practising as midwives throughout the country at the present time must be very large indeed. Many of these women will, from lack of education, from lack of means, or from lack of opportunity be unable to obtain the certificate necessary to enable them to continue their work. It is with the object of helping such as these and for the purpose of assisting poor women to acquire the necessary training that this association has been formed. The cost of training [illegible] about £20, a sum far beyond the reach of [illegible] who at the present time are pursuing [illegible] the new Act comes fully into force in 1905 a considerable demand for trained midwives is likely to arise and for some time it is probable that there will be a dearth of properly trained women. The livelihood to be gained by practice as a midwife amongst the poor must often be very small and very precarious and the initial expense will act as a deterrent to many who might wish to undertake such work. If a sufficient supply of fully trained women is to be provided for the poor it is necessary that the funds for their training should be contributed in many instances by the charitable public. The association undertakes to arrange for the training of suitable women in approved hospitals and other institutions and centres; it is anxious to coöperate in this work with local associations and it will be prepared as funds allow to make grants and loans in aid of training to associations and individuals. It is felt that in a large number of cases free training will have to be given under agreed conditions as to the subsequent work of the candidates, and it is also thought that a practical form of help may be in grants to local committees for the part maintenance of a midwife in districts too thinly populated to support one without such help. A home has been opened at East Ham by the association in coöperation with the Plaistow Maternity Charity, where four pupils at a time are trained in a crowded and very poor district under a competent midwife for the certificate of the Central Midwives Board. The objects of the association are worthy of all recognition and we hope that this appeal will meet with a favourable reception from those who have the interests of the poor at heart. As the registered midwife is now a legal institution it behoves us all, whatever we may think of the arguments that led to her creation, to see that she is a competent person. The offices of the association are at Hanover Chambers, 12, Buckingham-street, Strand, London, W C, to which address any donations may be sent.

THE ETIOLOGY OF LEPROSY.

IN an annotation which appeared in THE LANCET of Jan. 30th, p. 316, we expressed a hope that further investigations would be forthcoming which would corroborate or otherwise Mr. Jonathan Hutchinson's theory with regard to the connexion between fish-eating and leprosy. We have now received a copy of a special report by Dr. George Turner, medical officer of health of the Transvaal, entitled "Fish and Leprosy" (Government Printing Works, Pretoria, 1903). Dr. Turner does not agree with Mr. Hutchinson that the eating of decomposing or imperfectly cured fish is the chief cause of the prevalence of leprosy. In support of his view he points out that leprosy is fairly common in Basutoland. He thinks that it is probable that the disease was introduced amongst the Basutos by the Hottentots but he argues that it does not follow that the source of infection was cured fish. He considers such an occurrence most improbable because the Basuto in his own land does not eat fish; he never fishes; and will not eat fish given to him by others. Dr. Turner gives a table showing the proportion of cases of leprosy amongst the different races reported at the census of 1901 in the Cape Colony. It is shown that excepting those of European race the Kaffir is the least affected, then in order comes the Malay, the most frequently attacked being the Hottentot. Yet the Malay is essentially a fish-eater in whose hands the catching and "washing" of fish chiefly rest. Dr. Turner argues that if the theory regarding the etiological influence of cured fish were true leprosy should be most prevalent amongst the Malays; but, as he has pointed out, such is not the case. Probably the white man eats fish more frequently than does any other class of the population, with the exception of the Malay, yet he suffers least of all. A table is given showing the number and percentage of the patients in the Pretoria Leper Asylum on July 31st, 1902, and indicating those who had eaten fish before becoming lepers, the kind of fish consumed, and the variety of leprosy from which they suffered. The facts with regard to the white and coloured races are interesting. 95 per cent. of the white patients had eaten fish and 45 per cent. had partaken of cured fish. Amongst the coloured races only 30 per cent. had ever tasted fish of any sort and only 10 per cent. cured fish, and there was this result, as shown by the statistics, that there were fewer cases of leprosy in the asylum amongst those who had habitually eaten fish than amongst those who had not. These observations would seem to disprove the theory enunciated by Mr. Hutchinson and it will be interesting to observe whether Dr. Turner's conclusions are supported by other authorities.

THE BRITISH MEDICAL BENEVOLENT FUND.

WE publish in another column a brief notice of the annual meeting of the supporters of the British Medical Benevolent Fund and desire, not for the first time, to bring the claims of this charity prominently before our readers. The committee of the fund pleads earnestly for continued and increased help without which many of the urgent applications made to the charity must be passed over; and it brings, in our opinion, sound arguments forward why its efforts should be supported. The cost of administration is only just over 5 per cent. of the funds at its disposal and, as there is no canvassing, candidates for benevolent aid are spared the pain of publicity. All legacies are invested in trust securities and thus an assured income is obtained for the annuity department. We think that these considerations should recommend the fund to those benevolent persons who desire to see their gifts well administered and who hold that a charity should deal with the public and its immediate supporters upon strictly business principles. The British Medical Benevolent Fund does excellent and valuable work in an unostentatious and economical fashion, and we should be glad to hear that accessions to its funds enabled it to extend its operations.

A RARE DEFENCE.

ALTHOUGH the general public are not lacking in a proper gratitude for the services of the medical profession, yet when it comes to an expression of opinion dramatists, novelists, and satirists of all kinds have from the days of Molière chosen rather to hold the medical man up as an easy butt than to employ the forces of ridicule in his just defence. With all the more pleasure, then, did we read an article signed "S. R L." in the *Manchester Daily Dispatch* of Feb. 10th. The author of this article—whoever he is—writes "All for the Dear Doctor," and he is not only witty and amusing in the medical man's behalf and at the expense of those who decry him but also extremely sensible. To begin with, he holds sound views upon the value of a medical man's advice and attention, altogether apart from any drugs that the practitioner may or may not choose to employ. He deprecates the common way in which the medical man and the medicine are confounded, as though they were integral parts of one obnoxious whole. "One might as well give up the shoe maker because he did not make one able to walk about in bare feet," says our author, "as the doctor because his medicine does not provide a new stomach, or liver, or whatever the defective organ under treatment may happen to be." Again, "S. R. L." combats the way in which the man of the legal and the man of the medical profession are constantly viewed in the same light. The public, he says, regards one as the parasite of crime and the other as the parasite of disease. Yet, according to him, no comparison could be more unfair, for whereas the lawyer fosters litigation, upon which he fattens, the medical man spends his days in paradoxical but benevolent efforts to mitigate those very evils which are the source of his livelihood. "How easily," he says, "might an unscrupulous doctor terrify his patients and treble his income by magnifying their complaints and multiplying his own attendances, and how thoroughly in accord would such practice be with the lines on which business and other professions run. How entirely opposite, says our laudator, "is the behaviour of the family doctor," and we are glad to believe that the praises of "S. R. L" are well founded and widely deserved.

CYTODIAGNOSIS IN NERVOUS DISEASES.

THE study of the cerebro-spinal fluid and of other serous fluids of the body has opened up a new field of diagnosis in medicine. In some departments considerable results have already been achieved. The study of the cerebro-spinal fluid and its contained cell elements (cytodiagnosis) has been carried out with great success, especially by observers of the French school, an account of whose work has already appeared in THE LANCET.[1] The special methods of cytodiagnosis are being widely used in nervous diseases since Quincke devised his method of lumbar puncture whereby the fluid could be drawn off easily for study. In the *Medical Record* of Jan. 23rd Professor Charles L. Dana, of Cornell University, gives an account of his studies on a series of cases of various nervous diseases. Widal in 1900 reported several cases tending to show the value of cytodiagnosis and claimed for it an important place in the diagnosis of cerebro-spinal syphilis, tabes dorsalis, and general paralysis and his observations have been largely confirmed by others. The cerebro-spinal fluid exists normally in the subdural and pia arachnoid spaces under a pressure equal to that of from 40 to 60 millimetres of mercury, but under pathological conditions, says Professor Dana, it may rise to 800 millimetres. The specific gravity is from 1003 to 1004 but in inflammatory and other diseases it may rise to from 1008 to 1012. Normally it is clear but in disease it may be cloudy from the presence of cells and débris or may become blood-stained. In general paralysis and in cerebro-spinal meningitis the proteid constituents of this fluid are increased (Widal, Ravaut, Guillain). The disintegration of medullated nerve fibres, a process which occurs in cases of chronic alcoholism, is indicated by the presence of cholin in the cerebro-spinal fluid, a fact which was ascertained by Dr. F. W. Hastings in Professor Dana's patients. Phosphoric acid is, according to Donatti, simultaneously met with in the cerebro-spinal fluid, this substance and cholin being joint products of the disintegration of lecithin which exists in the myelin of the nerves. A systematic study and counting of the cellular elements were made in 22 cases by Professor Dana with the following results. In eight cases of general paralysis the lymphocytes or cells in the fluid varied from 16 to 135 per 100 fields of the hæmo cytometer. In two other cases of the same they averaged from three to six. Lymphocytes were found to be abundant in the fluid in cases of both general paralysis and of tabes dorsalis. In commencing alcoholic insanity and in Korsakoff's disease the cells varied in number from four to six per 100 fields, in cerebro-spinal meningitis they were more frequent and averaged 155, while in syphilitic disease of the brain or spinal cord they reached the very high average of 722. In cases of doubtful diagnosis between general paralysis and chronic alcoholism the existence of cells in the cerebro-spinal fluid tended to indicate the presence of the former disease, while the absence of cells enabled the investigator to exclude syphilis, tabes dorsalis, general paralysis of the insane, and multiple sclerosis. In meningo-myelitis of syphilitic origin, Professor Dana, the abundance of the cells i the degree of intensity of the morbid pro bacterial (streptococcal) inflammation was pr observed polynuclear leucocytes in the whereas in ordinary syphilitic diseas leucocytes were present. Mallory and that in tuberculous meningitis the pred cerebro-spinal fluid was the lymphoid (mo that in purulent meningitis polynuclear ponderated, and this is confirmed by Profes In the same issue of the *Medical Record* P Fraenkel of New York gives an account of 4 by him in regard to cytodiagnosis. Of thes cerebro-spinal fluid in sufficient amount for s included seven cases of tabes dorsalis, four paralysis, three of cerebro-spinal syphilis, seven o sclerosis, two of paralysis agitans, three of cerebra two of severe hysteria, and one each of poliomyelitis, diplegia, aural vertigo, hereditary syphilis, and rhino All the cases of tabes dorsalis presented a marked in of lymphocytes and in two of them polynuclear cells present. Three cases of general paralysis and six of mult sclerosis showed marked lymphocytosis as did two cases cerebro-spinal syphilis and one case of cerebral gumma. I all the other cases, adds Professor Fraenkel, the fluid was free from corpuscular elements. All the observations of Professor Dana and Professor Fraenkel were made under aseptic precautions.

THE CONGRESS ON CLIMATOLOGY AND URBAN HYGIENE AT NICE.

A FURTHER programme has been issued concerning this Congress. Though it is entitled the First French Congress of Climatothérapie et Hygiène Urbaine, the circulars concerning the same are printed in English and foreigners generally are cordially invited to attend. The object is to discuss the climatic treatment of disease and the hygiene of health resorts where such treatment may be attempted. With this programme it is but natural that the Congress should meet on the Riviera. We are told that the Congress "will consist of duly qualified French and foreign physicians, of scientific men whose works bear on the subjects to be discussed at this Congress, and also of representatives of the medical press." Application for membership must be made not later than March 15th and the entrance fee of 20 francs should be sent to the treasurer, Dr. Bonnal, 19, Boulevard Victor-Hugo, Nice A form will then be forwarded, on which the member must inscribe the details concerning the route by which he proposes to travel and he will then receive tickets which will entitle him to a reduction of 50 per cent. in the railway fare. Speeches in other languages than French may be delivered if the president approves. Several papers by well-known local practitioners are announced on the climatic effects of various Riviera resorts and Dr. Balestre, whose functions at Nice are the nearest French approach to those of an English medical officer of health, will read a paper on the Disinfection of Towns. Of course, there will be excursions and facilities given to investigate on the spot the various advantages offered for the treatment of the diseases that are most likely to be benefited by a change of climate. Professor Chantemesse of the Pasteur Institute will preside and Dr. Hérard de Bessé of Beaulieu-sur-M Alpes Maritimes, is the general secretary of the Cong All seems to have been well thought out and orga Indeed, if there is any fault it is rather that the r somewhat too much into detail and do not leave sufficiently open to the circumstances and moment. One rule, in any case, is sure to

---

[1] THE LANCET, May 30th, 1903, p. 1535.

It is undoubtedly very necessary to limit the duration of the speeches, though this is best done by a vote of the Congress itself given when the necessity of such limitation has made itself felt. But here we are told in advance that the time for reading papers must not exceed ten minutes and the speeches discussing these papers five minutes. It is absolutely impossible to treat complex scientific subjects in so short a time. The president is sure to allow speakers to overstep this narrow limit and once such a concession is made to one speaker it cannot be refused to others. A broader limit might be more easily observed and then something effective would be done to check undue loquacity. Undoubtedly as travelling becomes more and more easy there will be an increased tendency to utilise change of climate in the treatment of disease. Such congresses as that announced should facilitate this very natural and generally very agreeable method of treatment.

THE IMPERIAL YEOMANRY HOSPITALS' REPORT AND SIR ALFRED FRIPP.

WE were requested last week to publish the letters from Sir Alfred Fripp and the Countess Howe which appear on p. 605 of our present issue. Publication was delayed, however, by a communication which we received from Sir Alfred Fripp to the effect that his letter as it had appeared in the lay press was not as he had signed it. His apology, as we now print it, tallies with the document signed by him which has been produced for our inspection by Lady Howe's solicitor.

THE LONDON LICENTIATES' AND MEMBERS' SOCIETY AND THE LONDON CONJOINT DIPLOMA.

A MEETING of the London Licentiates' and Members' Society was held on Feb. 23rd, when Dr. F. J. Smith, the President, addressed the society. He explained clearly the circumstances, so often alluded to in THE LANCET, by which the provincial student has obtained so great an advantage over the London student in the securing of a medical degree, and pointed out that the public had begun to assume that a practitioner without a degree was in some way, on paper and in theory at any rate, inferior in medical attainments. The effect on the medical schools in London now was, he said, that for some years there had been a steady and nearly persistent increase in the number of students in the provincial schools and a decrease in those of the London schools, a result which it was thought the London teachers might have foreseen. They were told, it was true, that the Royal Colleges tried to obtain powers to grant a degree in medicine; that might be so but it was impossible to believe that their efforts were really thorough and unanimous and that they went steadily to work with the one object in view of relieving the difficulties of metropolitan students of medicine. The reconstructed University of London had copied the worst features of the old examining body of that institution and had grafted on to the old constitution but little of what was of use in the metropolitan schools of medicine. The petition of the London Licentiates' and Members' Society, setting forth these disabilities and difficulties, had been received by the Royal College of Surgeons of England very sympathetically and by the Royal College of Physicians of London with hardly the same spirit, but the meeting of a combined committee of the two Colleges led to nothing. The Colleges declined to approach the University of London with a view to any combined examinations. The association then appealed to the University of London whose reply was that it could not help them. The association has our best sympathies but we do not see how the object for which it is working, the granting of a medical degree to holders of the London diplomas or licence, is to be effected. We look forward confidently to the time when the medical degree of the University of London will be attainable by all capable and industrious London students, but no regulations by the University or the Colleges to assist in bringing about this result would be retrospective in their action.

THE LONDON SCHOOL OF TROPICAL MEDICINE: CRAGGS'S RESEARCH PRIZE.

A PRIZE of £50 will be awarded to a past or present student of this school who during the current year (October to October) makes the most valuable contribution to tropical medicine. Contributions must be written in English and essays must be sent in on or before Oct. 1st next to the Medical Tutor at the London School of Tropical Medicine, Royal Albert Dock, London, E., who will gladly afford further information.

SANITARY MARITIME AND QUARANTINE COUNCIL OF EGYPT.

IT is announced that the Quarantine Board of Egypt will dispose of five posts for medical officers at a monthly salary ranging from £22 11*s* to £28 14*s*. Competitors must be duly qualified either by a European faculty or by the State. Applications must be addressed to the President of the Quarantine Board not later than April 2nd, 1904, accompanied by (1) a copy of the candidate's diploma; (2) a certificate of practical work; (3) a certificate of good health; and (4) a formal engagement to take possession of the post, in case of nomination, during the month following the official notification. Candidates must also indicate the languages which they know. The administration reserves the right to send these medical officers, in succession, to the different ports of the Mediterranean and Red Sea. Their resignation cannot be accepted unless addressed to the Presidency of the Quarantine Board three months in advance.

SMALL-POX IN MADAGASCAR.

IN what way small-pox was first introduced into Madagascar is uncertain but there is evidence that the disease has long been prevalent in the island. Its dangerously infective character was early recognised and in the *Annales d'Hygiène et de Médecine Coloniales* for 1904 is given some account of the protective measures adopted before the French occupation of the country. At the beginning of the nineteenth century there was in vogue the primitive procedure of burying alive the unfortunate victims of the disorder, a penalty of death being exacted in the case of any person who attempted to disinter the body. This barbarous method was in time replaced by a rigorous isolation of the sick person who was confined in a pit to the edge of which food was brought by his friends, the patient apparently being otherwise left entirely to his own devices. Greater laxity marked the reign of King Radama I., in whose time the practice of vaccination on the lines of Jenner is said to have been employed, but his successor, Queen Ranavalona, returned to a great extent to the old régime. She forbade anyone who had not already had the disease to act as a nurse and prohibited the washing of infected clothing in running water, but so far as the sufferer himself was concerned seems to have contented herself with a policy of *laisser faire*. Under King Radama II. still less attention was paid to sanitary precautions and though after him Queen Rasoherina again checked the exhumation of those who had died from small-pox it was not until French influence became predominant in 1896 that modern hygienic methods can be said to have obtained a firm footing.

THE medical officer of health of the Cape Colony states that for the week ending Jan. 30th no case of plague was discovered throughout the Colony. Dead rodents were found at Port Elizabeth, East London, and Queenstown, but in the Cape Town and Harbour Board area although 221 rats were examined during the week none was found to be affected with plague. As regards the Mauritius a telegram from the Acting Governor, received at the Colonial Office on Feb. 19th, states that for the week ending Feb. 18th there was one case of plague and that was fatal. As regards Hong-Kong telegrams from the Acting Governor state that for the week ending Feb. 13th there were 2 cases of plague and 2 deaths from the disease and for the week ending Feb. 20th there were 1 case and 1 death.

Sir Edward H. Sieveking, physician extraordinary to His Majesty the King, died on Feb. 24th in his eighty-eighth year. He graduated as M.D. of the University of Edinburgh in 1841 and was well known for his work in connexion with diseases of the nervous system.

His Majesty the King of the Belgians has bestowed upon Dr. A. S Gubb, now of Algiers, the Civic Cross of the First Class for services rendered by him as honorary medical officer of the Société Belge de Bienfaisance de Londres.

The general condition of Sir Samuel Wilks is causing great anxiety and it is with sincere regret that we have to report that his strength and powers of resistance are declining.

Looking Back.

FROM

THE LANCET, *SATURDAY*, FEB. 25, 1826.

ROYAL COLLEGE OF SURGEONS.

On Saturday last, February 18th, a public Meeting[1] of the Members was held at the Freemasons' Tavern, to take into consideration the best means of remedying the abuses which exist in the government of this College. The number of gentlemen present was upwards of twelve hundred. At seven o'clock Mr. Lawrence entered the Hall, and, on the motion of Mr. Tyrrell, was immediately called to the Chair, amidst the loudest acclamations.

Mr. Lawrence.—In the year 1824, certain regulations were framed by the ruling body of the College of Surgeons, which I considered as having been directed against the whole body of the members of the profession. The substantial enactment is short but effective for its purposes. I will read the bye-law, if you please, before I enter upon any commentary :—

> "The Court of Examiners of the Royal College of Surgeons, in pursuance of their duty to promote the cultivation of sound chirurgical knowledge, and to discountenance practices which have a contrary [illegible] t.—That from and after the date hereof, the [illegible] recognised by the Court, be those of London, [illegible] asgow, and Aberdeen. That certificates of attendance upon the chirurgical practice of a hospital be not received by the Court unless such hospital be one of the above recognised schools, and shall contain, on an average, one hundred patients.
>
> "And that all certificates of attendance at lectures on anatomy, physiology, the theory and practice of surgery, and of the performance of dissections, be not received by the Court, except from the appointed Professors of Anatomy and Surgery in the Universities of Dublin Edinburgh, Glasgow, and Aberdeen, or from persons teaching in a School, acknowledged by the medical establishment of one of the recognised hospitals, or from persons being physicians or surgeons to any of those hospitals."

When men begin to legislate, inasmuch as the laws which they frame are to govern the conduct of others, they should express themselves in the plainest language, and avoid all ambiguity. This I take to be one part of the duty of legislators. Whether or not the enactments which I have just alluded to are calculated to promote "sound knowledge," and "discourage practices of a contrary tendency," I leave you to determine. Yet, Gentlemen, it is by such regulations as these—it is upon such miserable pretexts, that the great body of the profession, not only in London, but in the country, are disqualified from teaching the knowledge of their science to others, how great soever may be their peculiar superiority in imparting instructions, whatever be the stores of valuable information which a long course of industry and fortunate opportunities may have enabled them to amass.—(*Cheers.*) Gentlemen, it is necessary that we advert for a moment to the distinction which is *laid down* in this famous regulation, between winter and summer courses ; and first of all we observe that they require of the candidate, that he shall have attended three winter courses at least. Now, Gentlemen, I take the liberty to say that, as is sometimes the case with lawmakers, these excellent legislators require that which is absolutely impossible to be performed ! In London, Gentlemen, whatever may be the case elsewhere, there are, in fact, no winter courses given, at least no winter courses so called. We know very well that two courses of lectures are delivered in each year, the one commencing in October, the other in January. But that which begins in October is called, as you well know amongst the profession, and by the Lecturers themselves, according to their advertisements in the newspapers the "autumnal course," and that which commences in January is uniformly denominated the "spring course." You see, therefore, that the candidate cannot comply with the law ; there is no winter course of lectures for him to attend. (*Laughter and applause.*)

The next, Gentlemen, is a regulation of more extensive power—"That certificates of attendance upon the chirurgical practice of a hospital be not received, unless such hospital be in one of the above recognized schools," meaning those of Dublin, Edinburgh, &c. as above mentioned. In a subsequent clause of the same regulation, we find, that attendance on anatomical or other lectures, is not to be recognized, except from the appointed professors of the above schools, or "from persons teaching in a school acknowledged by the medical establishment of one of the recognized hospitals, or from persons being physicians or surgeons to any of those hospitals." I really profess myself unable to understand this jumble. In the first clause, the privileged hospital must be in one of the recognized schools, and in the next, the favoured school must be acknowledged by the medical establishment of one of the recognized hospitals ! Now, Gentlemen, to say nothing of the absurdity of supposing, as this regulation does, that anatomy and surgery may be taught by the *physicians* of a hospital, I do declare that I deem it to be impossible to have combined more confusion, more nonsense in the same compass, than are to be found in the limits of this short enactment. (*Applause.*) But, Gentlemen, I have a more material objection to state, and it is to the catalogue of the schools of instruction to which the privilege of recognition has been conceded—Aberdeen, Glasgow ! We know, Gentlemen, that at least anatomy cannot be studied in those places with any hope of success. We are all, I believe, aware, and no one is more ready than myself to acknowledge the great talents and acquirements of the Gentlemen at the head of the anatomical schools in those places ; but we are also aware that they are destitute of *subjects*[2] and without subjects, without the necessary means, no talents in the teacher, no acquisition of which he can boast, no peculiar fitness for the office of instruction on his part will avail the student in his study of anatomy. (*Applause.*)

---

[1] Excerpts only have been transcribed. The full report of the meeting occupied 37 columns of The Lancet. The speakers were Mr. Lawrence, Mr. Tyrrell, Mr. Wardrop, Mr. Wakley, Mr. Kingdon, Mr. Churchill, Mr. Welbank, Mr. Lloyd, Mr. Wakefield, Mr. Leese, Mr. Wigan, Mr. Dillon, Mr Ellerby, Mr. Waln, Mr. Macilwain, Mr. Ingram, Mr. Garland, and Mr. Paty.

[2] This statement was challenged in The Lancet of March 18th by Glaswegians, and Mr. Lawrence's reply, modifying the statement, appeared in The Lancet of March 25th.

Freemasonry.—*Rahere Lodge, No. 2546.*—A meeting of this lodge was held at Oddenino's Imperial Restaurant, Regent-street, London, W., on Tuesday, Feb. 16th, W. Bro. Ernest Clarke, F.R.C.S., being in the chair. The sanction of Grand Lodge to the change in the place of meeting was announced. At the request of Bro. Nunnerly the Master and Wardens signed a petition to Grand Lodge for the formation of a St. George's Hospital Lodge—the eighth hospital lodge to be established in London and the sixth which the Rahere, the oldest, has had the privilege of assisting to promote. A considerable number of the brethren subsequently dined together.

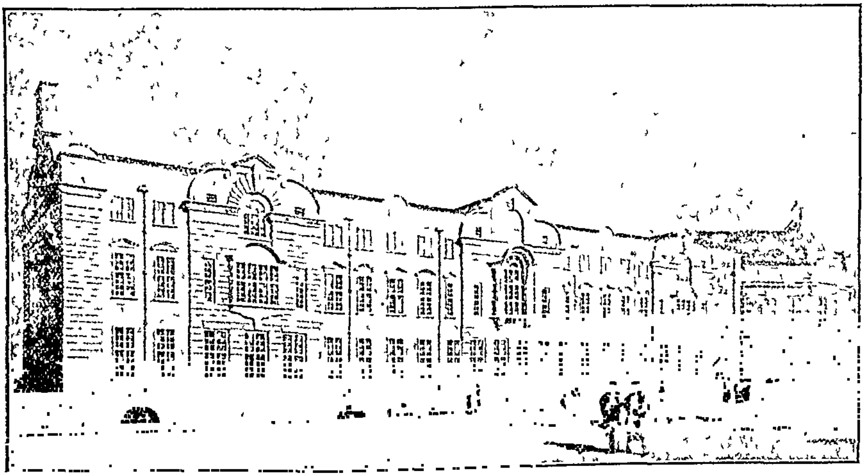
THE NEW SCIENCE SCHOOLS AT THE UNIVERSITY OF CAMBRIDGE.

THE MEDICAL SCHOOL.

THE new buildings of the Cambridge Medical School, which are to be opened on Tuesday next, March 1st, by His Majesty the King, accompanied at her special desire by Her Majesty the Queen, will provide accommodation for the departments of medicine, midwifery, surgery, and pharmacology. The same buildings will temporarily house the departments of public health, medical jurisprudence, and pathology, the last named being the department which will later receive expansion when the whole of the projected block is completed and when an Institute of Hygiene is prepared to carry on the work of instruction in theoretical and practical sanitation.

As will be seen from the plans (see Fig. 2) the block is shaped roughly as an L. The long arm of this L has its south façade facing Downing street and runs east and west to terminate at the eastern extremity in the Humphry Museum (see Fig 3) The short arm is not yet completed, but it will *run northwards from the Humphry Museum* to join the *older* buildings of the school, the ancient houses, which formed the original medical school, being removed. The new buildings are built of brick faced with Ancaster stone and, as will be seen by our illustration (see Fig. 1), are plain in style, no money having been wasted upon making what is meant to be a centre of hard practical work and progressive research wear the appearance of a palace or a temple. The classic ornamentation introduced upon the Humphry Museum is almost the only departure from the suitable severity of the building.

FIG 1.



New Buildings of Cambridge Medical School, Downing street Façade

The accompanying plans show clearly how thoroughly the needs of the modern medical student are to be met for the future at Cambridge. On the *Basement Floor* are situated workshops, store rooms, combustion and other experimental rooms, photographic rooms, and stable opening into a small yard, while we have here also the engine house and accommodation for the electric lighting, heating, and ventilating installations The heating and ventilation are carried on independently on the Sturtevant plenum system by means of two steam heaters, two fans driven by electric motors, a special air filter, and an elaborate system of ducts and flues built throughout the walls of the whole building. Air, therefore, is thoroughly washed, screened, and warmed before being distributed through the structure Electricity for light and power is developed by two 20 h.p Diesel oil engines coupled to two dynamos, while there is reserve current stored sufficient for an eight hours' supply in a battery of accumulators. Thus it will be seen that the plant has been particularly arranged to obviate immediate stoppage of the whole system in case of injury to any detail. Each ventilating fan is capable of doing three quarters of the warming of the whole building, and the accumulators would provide temporary electric current in case of stoppage of either of the dynamos

On the *Ground Floor* is the east entrance in Downing-street. Immediately to the left of this entrance are various private work-rooms, large demonstration and examination rooms, the medical and surgical departments, and the pharmacological laboratories with the private workrooms belonging to this branch of study. The entrance and staircase are spacious and are paved with black and white marble A large lecture room, built to accommodate a class of 200 students, is at the foot of this staircase, while facing are the pathological museum and two workrooms, one for pathology and the other at present for public health work. It will be noted by the plan that the big lecture-room receives practically no lighting from without but is dependent upon artificial light. This was done deliberately so that all available light could be used for the work rooms where the maximum of natural illumination is indispensable. In a lecture room not only is artificial light as good as natural light but it is even better, for the exact amount necessary for a demonstration can be focussed on to a *particular map or screen and maintained there steadily.* The method adopted at Cambridge of giving no outside wall to the big lecture room has already been imitated in other buildings having similar objects.

On the *First Floor* we have the Humphry Museum, the most elaborate feature of the pile. This is a nobly proportioned chamber, 62 feet long by 38 feet broad terminating with a bold and lofty semi octagonal eastern end (Fig 3) Over this is a dome supported by marble columns. The walls are lined with glazed tiles of varying depths of sea green in colour relieved with dull pink mouldings. The tiles are quite plain and flat and the scheme of decoration does not pretend to be other than tile

work. It is consequently satisfactory and effective. It is the work of Mr. Conrad Dressler. The cost of the Humphry Museum was largely defrayed by subscriptions from Cambridge medical graduates, so many of whom were pupils and friends of the great Cambridge teacher and surgeon. They cannot fail to be gratified at the use to which their subscriptions have been put. On the same landing is the library. This, like the Humphry Museum, is a lofty room and both, it will be seen from the plans, occupy space in two storeys. It is lighted from the top. The arrangement for storing books in stacks is ingenious, for each separate block of cases is moveable, allowing access to shelves behind. In this way it is hoped to house a very large reference library in quarters of modest dimensions. On the same floor are the private room of the Regius professor of physic, a research room for members of his class, and an operating room and a private room for the professor of surgery. This room communicates with a lecture room of 60 desks. On the same floor are admirably fitted class-rooms for elementary and advanced pathological work and work-rooms for the professor of pharmacology and his assistant.

On the *Second Floor*, at the end of the main staircase, is a small museum, to be used for teaching purposes. Here the student will have full access to all specimens and will be able to bring his text-books and note books and to record the result of his studies on the spot. Beyond this museum is a room already in use as a laboratory for pathological chemistry, in connexion with which is a photographic room. On the left side of the central staircase is a series of rooms lighted from the roof—viz., the room of the curator of the museum, a private research room, a larger room for experimental pathology, and a room which is at present being used by the department of hygiene. Further to the west are a work room and private room for the demonstrator of special pathology, two rooms used for the preparation of

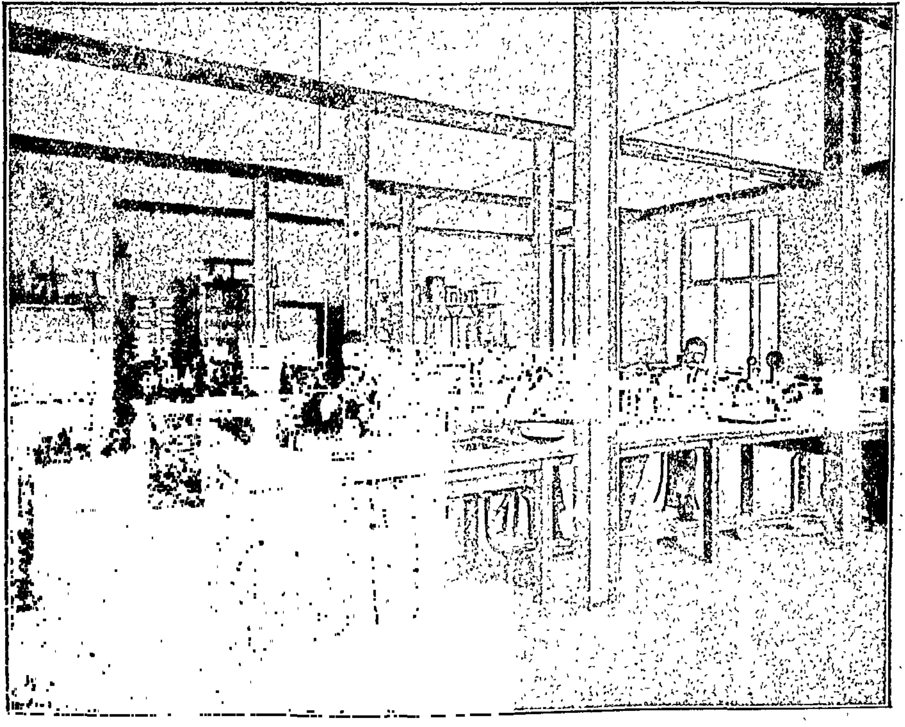
ich the
University of Cambridge is now providing for the scientific and technical education of the medical student, but this
does not do justice to
e responsible for the
y class rooms designed
either for research purposes or for the practical work of the students. In all of these the greatest care has been exercised to give the worker the maximum advantage. Hot and cold water, gas, and electric current are laid on in an accessible manner to every bench and all the plain furniture is strong and suitable. There is a lavish supply of cupboards, drawers, and lockers for the keeping of reagents, specimens, and microscopes, while the precautions taken against dust and dirt are elaborate. Concrete floors have been put in throughout and glazed surface channels are employed to take the waste water, &c., in all laboratories immediately outside. All the supply pipes and electric wires being carried in covered chases can be reached without breaking the walls or floors. The walls and ceilings are finished with a smooth concrete surface, all angles are rounded, and there are no skirting boards, but the walls join the floors in plain curves below, as they join the ceilings in plain curved cornices. All doors and all furniture have been made plain and flat, there are no mouldings or projections anywhere to catch dirt; the window sashes are of cast iron and great attention has been paid to the lighting, all the laboratories being splendidly lighted. The big class-room for 90 students on the top floor of the building is a model of what such a room should be. It is divided into two by a moveable partition and lighted from above in such a way that the back benches are just as good for microscopic work as the front benches.

FIG. 6.



A Laboratory in the Botanical School.

The responsibility for the design of the buildings rests with Mr. E. S. Prior, who has met fully the wishes of the various professors and teachers more immediately concerned with the Cambridge Medical School. Professor Sims Woodhead has been indefatigable in assisting him with his unrivalled expert knowledge. The work has been carried out by Messrs. Kerridge and Shaw. Mr. Wray, of Messrs. Sturtevants' firm, has supervised the engineering work.

THE GEOLOGICAL AND BOTANICAL SCHOOLS.

The King, as we announced last week, after inspecting the new medical school buildings will visit the new law school, the new botanical school and laboratory, and lastly, will visit the geological school and will unveil the statue in the Sedgwick Museum to the famous Cambridge geologist, Professor Adam Sedgwick. The three schools stand in the beautiful park ground, lying north of Downing College, which has been purchased recently by the University from that College. The botanical and geological schools which are built upon a common plan are dignified as well as beautiful buildings, thoroughly adapted to their modern purposes, and yet so built as to harmonise externally with the mediæval features of

Cambridge. The bright grey stone, relieved with red bricks and [illegible] exactly the right combination of solidity and [illegible] and Cambridge is to be congratulated upon these additions to the beautiful university city.

The accompanying plans of the botanical school, by the range of accommodation indicated, prove how thoroughly the science of botany is being taught at Cambridge, where the subject is now pursued not only as an ancillary science to medicine but as a department of agriculture. A large number of students take up botany as one of the subjects the natural science tripos, while the practical side of the subject is further recognised by those who wish to work at forestry. Every facility is offered to the student to observe with his own eyes [illegible] that may have a most [illegible] recent developments [illegible]

Parallel to, and just [illegible] the geological school, [illegible] face being shown a [illegible] fossil cabinets of John W[illegible] century geologist, w[illegible] ence of strata in th[illegible] collection made by [illegible] Professor T. McK. [illegible] 30 years ago, on the [illegible] posed to build a Se[illegible] name in the univer[illegible] his splendid specim[illegible] the middle of his [illegible] geological hammer [illegible] Tuesday next.

The new botanical school, the new geological school, and the new law school are all the work of Mr. T. G. Jackson, R.A., who has thus scored further successes in his long list of university and scholastic buildings.

FIG. 7.

The Sedgwick Statue, by Onslow Ford.

THE UNIVERSITY OF LONDON: THE INSTITUTE OF MEDICAL SCIENCES.

LETTER AND DONATION FROM HIS MAJESTY THE KING.

THE Faculty of Medicine of the University of London was summoned on Feb. 19th to "receive a communication from His Majesty the King in reference to th[illegible] of Medical Sciences." Mr. H. T. BUTLIN, [illegible] faculty, who presided over the meeting, took the opportunity of laying before the members the following short statement of the means which were being taken and the progress which had been made towards the attainment of the institute the establishment of which had been suggested by the faculty and approved by the Senate of the University.

In the summer of last year the Senate appointed a committee of appeal consisting of two senators who represent the faculty, Dr. J. Kingston Fowler and Sir Cooper Perry, the dean of the faculty, Mr. Butlin, and Dr. Lauriston E. Shaw, its honorary secretary. Dr. Fowler and Mr. Butlin were appointed joint treasurers, the former to represent the Senate and the latter on behalf of the faculty. The duty of drawing up an appeal for funds was intrusted to this committee and it was determined that in the first instance the appeal should not be made more public than was implied in sending a copy of it to every member of the Faculty of Medicine. It was hoped that some individual or individuals possessed of ample means might be found willing to furnish a sufficient sum of money to build and to equip, if not to endow, the institute so that it might not be necessary to issue a general appeal. That expectation had not at present been fulfilled, probably for reasons which would be referred to later. At one time, however, it was believed that successful negotiations towards this object would be carried through. In November last, o[illegible] Fowler, the Senate determined to issue [illegible] press an appeal for funds to build, to equ[illegible] institute. To a meeting of the Faculty of Medicine it must be a matter of interest that this, the first public appeal of the Senate for money, was made on behalf of the needs of medical education. The drawing up of the appeal and the manner in which it should be issued were again left to the appeal committee.

On Dec. 18th the letter of ap[illegible] number of lay and medical papers [illegible] very freely by both, and in every inst[illegible] was aware, most favourably. In fac[illegible] had ever been better received. In [illegible] favour of the establishment of the [illegible] to Lord Rosebery, as Chancellor of the University, signed by the treasurers or chairmen of nine of the hospitals to which medical schools are attached. The only names absent were those of the treasurers of King's College and University College Hospital, who excused themselves from signing on the ground that in the institutions with which they were connected the teaching of science is not confined to medical students.

On Feb. 1st Mr. Butlin received a letter from Sir Dighton Probyn, the Keeper of the Privy Purse, stating that the attention of His Majesty had been directed to the defects arising from the want of concentration of the teaching of the earlier subjects of the medical curriculum in London. The letter concluded in these terms: "As the King now learns that the University of London is making an attempt to remedy this defect by the establishment of an Institute of the Medical Sciences under its proper control, where the concentration of medical teaching will be carried out with every prospect of success, I am commanded by His Majesty to inform you that he is willing to contribute 100 guineas towards this Medical Institute should the scheme be carried out."

Mr. Butlin stated that the attention of His Majesty the King had been directed to the subject by Sir Francis Laking, whose strong interest in the welfare of the profession and in medical education was well known. He begged members of the faculty individually and collectively to do their utmost to assist the appeal committee. Owing to the scarcity of money the present time was peculiarly unfavourable to any and every form of appeal for funds and this appeal was not likely, without some explanation of those familiar with the facts, to be attractive to the general public. Medical education in London had always been carried on as a private enterprise and was regarded as so profitable to those who were engaged in it that an appeal for funds on its behalf seemed to many persons almost in the light of an impertinence. In spite of these difficulties he would point out what had been done in the course of eight weeks by the four persons who constituted the appeal committee. The appeal had been most favourably received by the lay and medical press, had been recommended by the treasurers of nine of the hospitals to which schools had been attached, and had been graciously and liberally responded to by His Majesty the King. The committee had received promises of donations to the amount of about £8000, including contributions from the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England. The University was indebted to Dr. Fowler, not only for his own handsome subscription of £250 but also for interesting Mr. Alfred Beit and Messrs. Rothschild in the proposal with the result that they had contributed £5000 and £500 respectively. If so much could be done in the face of serious difficulties in so short a time by so small a number of men what might not be done in the course of a few months by the largest and most influential faculty of medicine in the world? Amongst its members were men who had access to the houses of the [illegible] not merely to build and to equip the institute but to endow it handsomely for teaching and research.

Mr. H. W. PAGE moved and Sir FELIX SEMON seconded:—

That the Dean be requested to convey in suitable terms an expression of the gratitude of the Faculty of Medicine to His Majesty the King.

The motion was carried by acclamation.

THE IMPERIAL YEOMANRY HOSPITALS REPORT AND SIR ALFRED FRIPP.

THE following letters have passed between Lady Howe, as chairman of the Editing Committee of the Imperial Yeomanry Hospitals' report, and Sir Alfred Fripp relative to his evidence before the Commission on the War in South Africa:—

I.

11th Feb., 1904.

DEAR LADY HOWE,—In the course of the correspondence which has passed between us you take exception to certain views relative to the book on the Yeomanry hospitals expressed by me in the evidence I gave before the Commission on the War in South Africa. The statements in which these views were expressed were "that I did not think [illegible] many points inaccurate and might be called, if it was a money matter and was done in the City, 'cooked' so as to make an impressive number of figures," and that I knew that "a whole lot of statements as to services re[illegible] untrue," a[illegible] some of the [illegible]

From yo[illegible] caused by [illegible] they were [illegible] ask you to accept my assurance that I gave this evidence in perfect good faith and as the expression of opinions which I had honestly formed, I also now ask you to let me say that on reflection I think my conclusions were hastily come to and that even if they had been expressed in less sweeping language they are liable to a construction which goes beyond what was justifiable. The questions put to me were unus[illegible]k me by surprise. I was under the [illegible] a scientific question as to whether t[illegible] Yeomanry hospitals was such as I considered scientifically perfect and as such adequately described in the book. I replied hastily and I see on looking at the words I used that my language went beyond a mere expression of a simple opinion and I wish as handsomely and completely as I can to express my regret for what has been construed as allegations against the good faith of some of those with whom I was associated. To begin with my observations upon the Yeomanry hospitals were meant to be confined to the only one of which, as the opening statement of my evidence indicated, I had practical experience—namely, [illegible] working of the Imperial Yeoman[illegible] of the Yeomanry field hospital and [illegible] experience. I expressly stated in [illegible] north of Kronstadt and I had, and have, formed no opinion about them. As regards Deelfontein, I wish, in justice to myself, to say that I had in my posse[illegible]hich led me to doubt the ac[illegible] the entries as to patients [illegible] these returns which I had in [illegible]swer to an unexpected questi[illegible]urns have been challenged by people whose integrity I did not, and do not, for a moment intend to question and for whom as individuals I have much respect. It is possible that I may have been right and that they, and not I, have been misled, for in such a scene of hurry as prevailed in the early days of the hospital at Deelfontein it may well be that one or other of us was misinformed. What I hope is [illegible] will be accepted that I spoke under an impression [illegible] but which was formed on what I con[illegible] I still think that, judged by purely [illegible]ties used in the book would require [illegible] of them could be accepted as the [illegible] for an army hospital system in the [illegible]alification I unreservedly express my regret for statements which have given pain. If I have used language about the services they rendered which has given pain to those with whom it has been my privilege to be associated in a [illegible] patriotic endeavour I trust that they will accept this [illegible] convey to them a full [illegible]

ALFRED D. FRIPP.

II.

11th Feb., 1904.

DEAR SIR ALFRED FRIPP,—On behalf of myself and the Editing [illegible] Yeomanry hospitals report I have pleasure [illegible]xpression of regret contained in [illegible] are offered.

Yours sincerely,
(Signed) GEORGIANA HOWE.

MEDICINE AND THE LAW.

An Action against Medical Men in Ireland.

IN a somewhat remarkable action a young man in Ireland recently sued two medical men, one of whom was his brother-in-law, for conspiracy, false imprisonment, and assault in connexion with placing him in a lunatic asylum. Owing to their conduct he claimed that he had been deprived of property by his father who had altered the dispositions in his will. At the trial of the action the jury negatived the charges of conspiracy and false imprisonment but disagreed with regard to the assault, and the judge, in giving judgment for the defendants, deprived the second medical man, Mr. N. J. Meehan, of his costs on account of an irregularity in connexion with the certificate which he had signed. The Court of Appeal at Dublin has now upheld the verdict of the jury and has refused to grant the plaintiff a new trial, and in doing this has awarded to Mr. Meehan his costs, considering that he was influenced by no malice or other improper motive and that consequently he had done nothing to deserve deprivation of them. The nature of the attack upon the two defendants may be judged from the fact that the father who had desired not to leave his property in the control of his son had himself been one of the most firmly convinced of his son's alleged mental condition and been directly concerned in placing him under treatment. Under the English Lunacy Act of 1890 a medical man signing a certificate, or any person doing anything in pursuance of the Act, is not liable to legal proceedings if he has acted in good faith and with reasonable care. There does not, however, appear to be any provision of this kind in the Acts relating to lunacy in Ireland.

Lead in Cream of Tartar.

At Stratford police-court on Feb. 13th a fine of £5 was inflicted upon a defendant for selling cream of tartar in which lead was found in the proportion of three-quarters of a grain to the pound. The presence of the lead was attributed to contact with lead vessels in the process of manufacture. Evidence was given as to the cumulative nature of the poison and it was stated that a case of illness had been traced to lead present in cream of tartar.

Litigation over the Sale of a Practice.

The action of Gibson *v* Ross, tried on Feb. 17th by Mr. Justice Walton and a common jury, presented no features which are not unhappily common to such cases. It was brought to recover money due under a promissory note given in respect of the purchase of a medical practice and the defendant counter-claimed for the cancellation of the promissory note, the repayment of money already paid by him, and other relief in respect of his bargain on the ground that the value of the practice had been misrepresented by the vendor. The defendant was unsuccessful in respect of the issue thus raised and the plaintiff obtained judgment upon the claim and counter claim. The only observation to which such a case can give rise (besides the obvious one that purchasers of medical practices should make very careful inquiries before they buy) is that such disputes had far better be settled by arbitration than fought out in a court of law. There is generally no evidence which could not be more fully appreciated by a carefully selected arbitrator than by a jury and the undesirable publicity given to damaging allegations and recriminations brought by one professional man against another would be avoided.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9075 births and 5420 deaths were registered during the week ending Feb. 20th. The annual rate of mortality in these towns, which had been 19 4, 17·2, and 18 4 per 1000 in the three preceding weeks, rose again to 18·5 per 1000 last week. In London the death-rate was 17·8 per 1000, while it averaged 18·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8 3 in Tottenham, 9 6 in Hornsey, 11 0 in Stockton-on-Tees, 11·4 in Handsworth (Staffs), 11 6 in East Ham, 12 0 in Northampton, 12 2 in Leyton, and 12·3 in Croydon; the highest rates were 23·9 in Nottingham and in Liverpool, 24·1 in Salford, 24·3 in Oldham, 24·9 in Preston, 25 6 in Plymouth and in Warrington, 25 8 in Merthyr Tydfil, and 27 9 in Bootle. The 5420 deaths in these towns last week included 493 which were referred to the principal infectious diseases, against 497, 412, and 449 in the three preceding weeks; of these 493 deaths 191 resulted from whooping-cough, 119 from measles, 70 from diphtheria, 48 from diarrhœa, 37 from scarlet fever, 21 from "fever" (principally enteric), and seven from small-pox. In Croydon, Southampton, Reading, Walsall, Aston Manor, York, and in nine other smaller towns no death from any of these principal diseases was registered, while they caused the highest death-rates in Norwich, Stockport, Wallasey, St Helen's, Burnley, Preston, Leeds, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Norwich, Stockport, Warrington, Preston, Huddersfield, Leeds, Sunderland, and Rhondda; from scarlet fever in Merthyr Tydfil; from diphtheria in Willesden, Hanley, and Salford; from whooping cough in Portsmouth, Wallasey, Liverpool, Wigan, and Gateshead; from "fever" in Preston; and from diarrhœa in Rhondda. Of the seven fatal cases of small-pox registered in these towns last week two belonged to Hull and one each to London, Derby, Wigan, Manchester, and Gateshead. The number of small-pox cases remaining under treatment in the Metropolitan Asylums hospitals, which had been 21, 25, and 24 at the end of the three preceding weeks, had risen again to 29 at the end of last week; nine new cases were admitted during the week, against four, eight, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, Feb. 20th, was 1620, against 1651, 1657, and 1644 on the three preceding Saturdays; 143 new cases were admitted during the week, against 168, 169, and 162 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 429, 347, and 324 in the three preceding weeks, rose again to 349 last week, and were 75 above the number in the corresponding period of last year. The causes of 63, or 1·2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Manchester, Salford, Leeds, Newcastle-on-Tyne, and in 50 other smaller towns; the largest proportions of uncertified deaths were registered in West Bromwich, Birmingham, Liverpool, Warrington, Blackburn, Preston, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·4, 18·5, and 19·2 per 1000 in the three preceding weeks, further rose to 22·2 per 1000 during the week ending Feb. 20th, and was 3·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 18 1 in Edinburgh and 19·4 in Leith to 24·7 in Greenock and 25 8 in Dundee. The 733 deaths in these towns included 26 which were referred to whooping-cough, 19 to measles, 18 to diarrhœa, six to diphtheria, five to small-pox, and one to "fever," but not any to scarlet fever. In all, 75 deaths resulted from these principal infectious diseases last week, against 62, 44, and 72 in the three preceding weeks. These 75 deaths were equal to an annual rate of 2·3 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 16, 15, and 24 in the three preceding weeks, further rose last week to 26, of which six were registered in Aberdeen, six in Leith, five in Dundee, four in Glasgow, three in Edinburgh, and two in Paisley. The deaths from measles, which had been 12, seven, and 21 in the three preceding weeks, declined again to 19 last week, and included eight in Glasgow, five in Dundee, four in Paisley, and two in Greenock. The fatal cases of diarrhœa which had been 17, 11, and 20 in the three preceding weeks, decreased again last week to 18, of which 15 occurred in Glasgow. The deaths from diphtheria, which had been three in each of the two preceding weeks, rose to six last week and included four in Glasgow and two in Aberdeen. The fatal cases of small-pox, which had been three, three, and one in the three preceding weeks, rose again last week to five, of which three were registered in Greenock and two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 128, 129, and 126 in the three preceding weeks, increased again to 167 last week, but were 58 in excess of the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25 6 30 5, and 27 2 per 1000 in the three preceding weeks, rose again to 29 7 per 1000 during the week ending Feb. 20th. During the past four weeks the death-rate has averaged 28 3 per 1000, the rates during the same period being 18 1 in London and 16·7 in Edinburgh. The 216 deaths of persons belonging to Dublin registered during the week under notice were 18 in excess of the number in the preceding week and included 16 which were referred to the principal infectious diseases, against 14, 12, and ten in the three preceding weeks; of these, nine resulted from whooping cough, three from "fever," two from diarrhœa, one from measles, and one from diphtheria, but none from either small-pox or scarlet fever. These 16 deaths were equal to an annual rate of 2 2 per 1000, the death-rates last week from the principal infectious diseases being 1 6 in London and 0 6 in Edinburgh. The fatal cases of whooping-cough, which had been 11, nine, and six in the three preceding weeks, rose again last week to nine. The deaths referred to "fever" numbered three last week, against one in each of the three preceding weeks. The two fatal cases of diarrhœa corresponded with the number in the preceding week. The 216 deaths in Dublin last week included 43 among children under one year of age and 64 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight excess over the respective numbers recorded in the preceding week. Five inquest cases and three deaths from violence were registered, and 93, or more than 43 per cent., of the deaths occurred in public institutions. The causes of six, or nearly 3 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: H. W. Macnamara to the *President* for three months' hospital study; H. Holyoake to the *Resolution;* J. H. Beattie to the *Andromeda;* and D. T. Hoskyn to the *Crescent.* Staff Surgeon: H. W. Finlayson to the *Scylla.* Surgeons: A. E. Merewether and W. K. D. Breton to the *Crescent;* R. Dickinson to the *St. Vincent;* R. Kennedy to the *Andromeda;* and J. Martin to the *Scylla* and to the *Terpsichore.*

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentlemen have been appointed Surgeons:—Edward John Steegman and Herbert Robert Power (dated Feb. 13th, 1904).

ROYAL ARMY MEDICAL CORPS.

The date of the promotion of Lieutenant-Colonel J. F. Williamson, C.M.G., is Nov. 20th, 1903. The date of the reversion from the Seconded List of Captain T. H. M. Clarke, C.M.G., D.S.O., is Nov. 23rd, 1903.

The undermentioned Lieutenants to be Captains (dated Jan. 29th, 1904):—A. J. W. Wells, G. F. Sheehan, H. H. Scott, H. A. Bransbury, M. W. Falkner, R. N. Woodley, E. Ryan, E. E. Parkes, J. V. Roche, A. J. Hull, R. V. Cowey, J. Conway, J. H. Barbour, F. E. Robinson, S. Mason, J. S. Bostock, and A. H. McN. Mitchell.

Lieutenant A. O. H. Gray is seconded for service under the Foreign Office (dated Feb. 4th, 1904). Captain and Brevet Major A. F. Tyrrell is placed on half-pay on account of ill-health (dated Feb. 11th, 1904). Captain R. M. Le H. Cooper retires on a gratuity (dated Feb. 13th, 1904).

The undermentioned gentlemen to be Lieutenants on probation (dated Jan. 30th, 1904):—Godfrey Faussett Rugg, Douglas Stokes Brownlie Thomson, Arthur Samuel Arthur, John Fairbairn, Robert Grenville Anderson, Leonard Bousfield, James Henry Douglass, Dumaresq Le Bas, Robert Robinson Lewis, Charles Harold Turner, Frank Herbert Noke, George Elliott Cathcart, Eugene Christopher Whitehead, Travis Clay Lucas, John Archbold Turnbull, William Wiley, Richard Brassey Hole, Alexander Loftus Otway, Walter Frederick Hamilton Vaughan, Montague Frederick Grant, Howard Harding, David Patrick Johnstone, Edward Henry Milner Moore, Frederick Joseph Garland, Michael David Ahern, Harry Bertram Connell, George Sullivan Clifford Hayes, Sidney Clement Bowle, Alban Anderson Meaden, and Robert John Cahill. The undermentioned Lieutenants are seconded under the provisions of Article 349 of the Pay Warrant: R. G. Anderson (dated Jan. 30th, 1904), S. C. Bowle (dated Jan. 30th, 1904), and F. H. Noke (dated Jan. 30th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Dorsetshire: The un[illegible] — Thoma[illegible]rd Telford [illegible]e: Joseph Grant-Johnston to be Surgeon-Lieutenant (dated Feb. 20th, 1904.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant V. Graham, 2nd Volunteer Battalion the York and Lancaster Regiment, to be Surgeon-Lieutenant (dated Feb. 20th, 1904); Surgeon-Lieutenant N. P. Watt to be Surgeon-Captain (dated Feb. 13th, 1904).

The notification which appeared in the *London Gazette* of Feb. 2nd, 1904, stating that Surgeon-Captain W. P. Peake ceased to belong to the Army Medical Reserve of Officers, is cancelled.

THE ITALIAN RED CROSS ASSOCIATION.

The public utility of the Associazione Italiana della Croce Rossa was recognised by a law dated March 30th, 1882. The society is allowed to coöperate with the sanitary department of the army by providing war hospitals, which are organised exactly like the army field hospitals and hospital trains, and by establishing infirmaries at railway stations. It is also empowered to take charge of, and to distribute, the gifts destined for the benefit of soldiers on active service and to set up an information office where friends and relatives can obtain information regarding combatants on both sides. The president of the central committee of the association is named by the King on the proposition of the Ministers of War and Marine. When troops are mobilised this official becomes the sole intermediary between the society and the Ministers. The agents who accompany the forces are under the orders of the military authorities and must conform to military rules. In recruiting its *personnel* the society can only engage men who, except that they may belong to the national militia, are entirely free from military obligations. In 1902 the association had about 25,000 members and disposed of resources, cash, and material valued at upwards of 6,500,000 lire. It was able to place the following equipment at the disposal of the Minister of War: eight hospitals of 100 beds each, 41 hospitals of 50 beds each but capable of expansion to 100 beds, 54 mountain ambulances, 244 dressing posts for railway stations, 15 hospital trains, two river ambulances, two hospital ships, and eight depôts for sanitary material. The *personnel* of the society is exercised as often as possible and to this end it always takes part in autumn manœuvres. In 1900 six field hospitals were mobilised, as well as one mountain ambulance and two hospital trains (one in Sicily and the other at Bari). The society has also taken a share in aiding the agricultural population of the Roman Campagna which every year is decimated by malaria. Since 1899 eight ambulances have done duty in the most exposed parts of this insalubrious region. As may be supposed the Red Cross Association is very popular in Italy. In addition to this admirable organisation there is another association in Italy—namely, that of the Italian Military Knights of Malta—which undertakes to afford aid to the sick and the wounded in war time. By special favour this society enjoys complete autonomy as regards its internal affairs but on service the agents are, of course, under military control. The members wear the red cross as well as the cross of their order. At present the society possesses three hospital trains, each fitted for 280 patients.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets William Macleod, C.B., R.N. (retired), on Feb. 17th, at his residence in Mornington avenue, West Kensington, aged 84 years. In 1842 he entered the Royal Navy as an assistant surgeon and served on the China Station from 1845–47. Under Admiral Sir Thomas Cochrane he was landed from the *Agincourt* in medical charge of the detachment of Royal Marines and took part in the capture of the forts on the river Borneo and the city of Bruni. During the Crimean War he was surgeon of the *Driver* in the Baltic and of the *Madagascar* in 1859 at Rio de Janeiro during a severe epidemic of yellow fever. He received the Sir Gilbert Blane's medal for his official records relating to the epidemic. In 1866 he was promoted to the rank of Deputy Inspector-General and was in charge of the Royal Naval Hospital at Yarmouth until 1875, when he was promoted to the rank of Inspector-General. He retired in 1880, receiving from the Admiralty an expression of its high appreciation of the manner in which he performed the arduous and responsible duties devolved upon him at Yarmouth. He received the Companionship of the Bath in 1880.

Brigade-Surgeon William Henry Harris, A.M.S. (retired), on Feb. 16th, in his seventy-fourth year. He joined the army as assistant surgeon in 1855 and served in the Crimea, taking part in the siege and fall of Sevastopol and the battle of the Tchernaya (medal with two clasps and Turkish medal). During the Indian Mutiny he was present with Colonel Maxwell's column in the operations before Calpee in 1858, proceeding with it to the Alumbagh during the capture of Lucknow. He was at the surrender of the forts of Ahmatee and Shunkerpore, took part in the pursuit of

Beni Madhoo across the Gogra, and the subsequent operations in Oude (medal). He retired in 1886 with the honorary rank of brigade-surgeon.

Deputy-Surgeon General William Bisset-Snell, A.M.D., at his residence, Onslow-gardens, W., at the age of 73 years. He entered the medical service of the army in 1855 and served throughout the campaign of 1860 in North China (medal with two clasps) and was promoted for "meritorious services."

CONVALESCENT HOMES.

An army order states that the convalescent home at Osborne, Isle of Wight,[1] presented to the nation by H.M. the King for the reception of officers of the navy and army, will be opened on April 6th. The accommodation will be divided equally between the two services and will provide for 38 single officers and five married officers (who may be accompanied by their wives). Children will not be allowed to live in the home. Officers will be admitted on the recommendation of the directors-general of the medical departments of their respective services, to whom all applications for admission should be addressed. The Commander-in-Chief in India has been requested to issue similar instructions and the names of officers of the Indian army will be submitted for admission to the Director-General of the Army Medical Service. The only payment required will be that laid down in Para. 65, Allowance regulations—viz., 2*s.* 6*d.* per diem for each officer or his wife. In connexion with the Convalescent Home at Osborne a hospital will be opened at the same time in London for the reception of officers of the navy and army requiring medical or surgical treatment prior to their removal to Osborne. The daily charge will be the same as that at Osborne.

THE NEWLY CONSTITUTED ARMY COUNCIL.

The omission of the name of any representative of the Army Medical Service on the Army Council has very naturally been regarded as placing that service at a serious disadvantage. The medical department differs from many other departments and has important claims to direct representation, a fact which Mr. Brodrick fully recognised and provided for. The difficulties with which the Army Medical Service has always had to contend has largely arisen from the absence of any direct representative influence and of any opportunity to make its wants properly known in high places. The late War Minister made a real attempt to rectify this and the alteration of his design is a retrograde step.

Correspondence.

"Audi alteram partem."

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of THE LANCET.

SIRS,—Time was when the practice of medicine throughout the country was mainly in the hands of physicians, who reaped the emoluments and left their prescriptions to be dispensed by an inferior body named apothecaries, and their surgery to the barbers of the day. As time went on these apothecaries improved their knowledge and acquirements, divided themselves into surgeons and apothecaries, either separately or in combination, and having obtained the ear of the people gradually nudged themselves into the position of, and shunted, the physicians. The apothecaries and surgeons, in fact, absorbed the cream of the practice in the country, and excepting in the instance of the great minds in the large towns and cities of the land, left but poor skim milk for the hosts of physicians. History, we are told, repeats itself, and one notices that there is at this time in the mind of some a disposition to disregard the teaching of past experience and, following the example of the old physicians, to look down upon the technical practice in connexion with the dispensing of medicines as unworthy of their dignity and gentility. Certainly it may be said to be the experience of the history of the past that those who combined their practice with the oversight of the drugs they supplied were the men who obtained the greatest and most conspicuous reward.

But it is not the object of this letter to treat the subject on these lines alone, although the policy may very well form a serious part of the argument. I desire to consider it from a much higher platform than that of personal pecuniary interest. Will it be for the good of the public? This seems to be the first and greatest consideration. In so far as it regards practice amongst the rich in great towns and cities, the dispensing of medicines by the practitioner may not be a very important or necessary factor. With the poorer and working classes it will be a very different matter. They will be obliged to consider cheapness and to save wherever they can, and rich and poor are alike, though from different reasons, prone to consider *cost.* The practitioner who obtains his drugs from the wholesale druggist and gets his living by his advice and attendance can naturally afford to employ the required medicines at a less cost (prime cost) than one who has to get his living out of the profit from the medicines themselves. He is also very careful to obtain medicines that can be relied upon for their purity and perfection, as this gives him confidence in their application. Prescriptions that may be taken to anybody lend themselves easily to cheap substitution and confidence must be weakened by poor results. If the practitioner suggests their being made up by a particular firm some underhand collusion may be hinted at by an unfriendly critic. Of course, at the present time anyone, be he physician, surgeon, or general practitioner, has perfect liberty in this matter to retain or to dismiss dispensing from his practice. But our agitators are not content to leave the members of our profession *free* to act as they think best, but they seek power to tyrannise over the rank and file who think quite differently from them on this subject. Those gentlemen can hardly have had much experience of general practice or country work. Here, and especially in the country, the practitioner must be self-reliant and self-contained; he must be an adept with his tools, whether they be medical or surgical; always ready by day or night to supply at the shortest notice whatever the nature of the case demands. His patients know the man and trust him thoroughly and are sure that they can always obtain from him whatever is required of the very best of quality and whenever needed. Should the preparation of medicines pass from his superintendence this confidence would be greatly shaken and in the case of the poorer classes it would be a positive calamity. The increased cost of the doubled sources of supply would be a serious consideration and would pretty certainly lead to the *run* being upon the physic and the compounder and the *curtailment* on the supervision of the practitioner.

Everyone engaged in full general practice will, I imagine, have a considerable number of patients on the borderland of great poverty. Most of us, I suspect, regard this residuum as a call upon our benevolence and Christian charity. It is easy to do very kind, useful, and acceptable work in this way with no loss to the general profession and but little, and sometimes even no, cost to the individual benefited, and the profession has reason to pride itself on its generous acceptance of this great duty. Generosity towards the wants of the real poor has always been the distinguishing characteristic of the medical profession. The professional man can control and regulate this charitable disbursement effectually and at comparatively small cost to himself if he supplies the medicaments but not so when they are removed out of his ken. Beyond the organised charity of hospitals and dispensaries there exists a numerous class that will not apply to either; though very poor they are very independent and cannot brook charity and wish to pay. It will be a bad day for the profession when it adopts methods which will make it impossible to meet such cases in the most sympathetic and kindest manner.

I know perfectly well that the profession is greatly imposed upon but not by the class of which I am writing. People who can well afford to pay 20 or 30 guineas for an operation are not ashamed to enter a hospital and to get the work done for nothing. But every general practitioner knows, or is soon able to ascertain, as to the means and circumstances of his poorer patients and he need rarely be deceived much about them. Perhaps the best disposed and widest spread charity of the profession is carried on by the general practitioners of the country out of the largeness of their hearts and in the most self-denying, unobtrusive, and effective manner.

It appears to be the wish of some to stigmatise this kind of practice as traitorous to the profession. I cannot think for a moment that the British Medical Association, which has done so much to advance the interests, honour, and prestige of the profession, will consent to support or to champion any such views. The gentility of the profession depends upon the individual man himself. Is he by education, manners, and conduct fitted to mix in the better ranks of society or is he not? That is the question society will ask. And it thinks neither more nor less of him because he superintends the dispensing of his own medicines than it does of the family lawyer, the welcome guest, who keeps his own offices and superintends the work of his own clerks.

---

[1] See THE LANCET, Jan. 30th, 1904, p. 320.

I am, Sirs, yours faithfully,

Huddersfield, Feb. 14th, 1904. SAMUEL KNAGGS.

To the Editors of THE LANCET.

SIRS,—With regard to the proposal to prohibit medical practitioners from dispensing may I be permitted as a general practitioner to bring the following to your notice. We have already druggists prescribing and dispensing, district nurses attending midwifery and prescribing and dispensing medicine, certified midwives, large numbers of well-to-do shopkeepers and the great majority of the working classes paying 1*d.* or less a week into clubs for attendance and medicine, Poor-law authorities doing their utmost to minimise our fees, impecunious parsons and their numerous relatives receiving gratuitous attendance, cottage hospitals, myriads of already dispensed prescriptions on sale in the form of tabloids, microscopic fees, and our "tiller of the soil" who, having owed a bill for three or four years, blandly expects half the amount to be taken off (when the whole sum asked for would be scorned by any self-respecting cabman for the same mileage) and who would certainly consider, unless supplied with something tangible in the shape of medicine, that he had received nothing in return for his money.

Again, can we depend on the quality of drugs and the accuracy of dispensing by all druggists? For obviously if a drug is not to hand there is no check on substitution. And though, far from wishing to impute such practices to druggists as a class, yet no large body of men are above suspicion and it is well known that such instances have occurred. Personally, I dislike and think dispensing undignified—a dislike which I am sure is shared by many of my fellow practitioners. At the same time it is obvious that general practice will soon become impossible for men with small means who after years of toil and hundreds of pounds spent to enter the profession will have laboured in vain to gain a livelihood, and in the near future the country doctor will become as extinct as the dodo, and general practice will have to be reserved as a pastime for those of ample means who may treat such cases as have advanced a step beyond the ken of the prescribing druggist, the village nurse, the certified midwife, &c., and the urgency of which is so great that even the frantic exertions on the part of "the lady of the village," with her swift-running motor, would fail to convey suffering humanity to the nearest hospital in time to sing the "Nunc Dimittis."

I am, Sirs, yours faithfully,

Chard, Somerset, Feb. 20th, 1904. NAPIER CLOSE.

To the Editors of THE LANCET.

SIRS,—Nothing, I am convinced, will so uplift the medical profession as the cessation of dispensing by medical men. Not that we are not competent for the task, but that the more imperative claims of other departments of medicine make it necessary that we should utilise the dispensing druggist as we have already the trained nurse. Then, indeed, will the reproach of lack of scientific advancement be removed from the profession in Britain, as it has from our brethren on the continent, and we shall receive our rightful social recognition with the Bar and the Church. It is doubtless the fact that many practitioners must supply medicines to their patients, but even this it is easy to arrange with the druggist, as is done in Dublin, where a pharmacist often arranges to supply all the medicines which a practitioner may order for a certain club for a proportion of the fee—generally one-fourth. Thus, if a medical man take a club worth £20 per year, the druggist agrees to supply all the medicine required for £5. Of course, some confidence and sweet reasonableness are required on both sides; but druggists like to do dispensing in such cases at almost the price of the drugs. A very important point is that the practitioner is not then compelled to confine himself to the few drugs which he would keep in his own surgery but is free to avail himself of all the resources of the Pharmacopœia.—I am, Sirs, yours faithfully,

J. C McWALTER, M.A., M.D.Brux., D.P.H.

Dublin, Feb. 20th, 1904.

To the Editors of THE LANCET.

SIRS,—Surely all this talk about compelling medical men [illegible] be a joke; if it is not, then all I [illegible] to interfere with the liberty of the [illegible] When I passed the College and [illegible] I gave no undertaking (nor was it expected of me) not to dispense but looked forward to practice with that understanding. If it is to become law in the name of conscience let it not be made retrospective but only to apply to men commencing practice after a certain date, then they on joining the profession would see their way clear. I should like to know who are the men who started this fad of "dispensing with dispensing." I will wager that if a *plébiscite* of the profession were taken the vote would be pretty decidedly "No." Could you, Sirs, kindly undertake to receive at your office a simple "Yes" or "No" as to the desirability of the proposed innovation? A post-card would be sufficient. These things by supineness sometimes slip through and then we say, Who would have thought it? and hundreds of practitioners would be put to serious straits. I am, Sirs, yours faithfully,

A SUBSCRIBER TO THE LANCET FOR OVER 40 YEARS.

Feb. 16th, 1904.

To the Editors of THE LANCET.

SIRS—If it is possible to make it illegal for a medical man to dispense medicines under a penalty of £100 I would be glad to know if it would not be possible to make it illegal to attend midwifery cases under a similar penalty. Of course, our female population has now an order of professional ladies to attend these cases. Or, say, for a consultant to write a prescription under a penalty of £1000. Consultants could, of course, afford the larger penalty seeing their larger income. I am quite at one with "L R C.P." who writes in THE LANCET of Feb. 13th. The Bill would mean ruin to half the general practitioners of to-day. What most people want to know is, Of what benefit is the Bill to be to anyone except the druggist? Is a druggist originating it?

Is the profession as a whole to benefit? Certainly let us look to our [illegible] Will it not be foolis[illegible] a little to either of [illegible] is of the profession will not be much improved by half of us going through the bankruptcy court. Let us attend to that prescribing druggist.—I am, Sirs, yours faithfully,

Feb. 20th, 1904. FAIRPLAY.

THE INQUEST ON WHITAKER WRIGHT.

To the Editors of THE LANCET.

SIRS,—I am glad [illegible] former letter as Dr. Willia[illegible]stion only that part of it [illegible] the body and the *fluidity* of the blood are neither separately nor together distinctive of poisoning by prussic acid" In fact, he calls in question only the first half of this twofold assertion—namely, that which relates to the *bluish tint* of the body which he regards as "pathognomonic if seen soon after death."

Now, I do not for one moment deny that both the signs referred to by me as the only criteria adduced by Dr. Freyberger, in addition to the odour, are generally observable in cases of prussic acid poisoning. But what I insist upon is that neither is peculiar to that form of death. Almost any text-book on forensic medicine will serve to refresh our minds on this subject. Since Dr. O'Neill has selected Taylor's I will take Guy's (second edition, 1861). Here are a few extracts: "Sudden death, unattended by hæmorrhage or effusion of blood, is characterised by extensive lividity. ...... Cadaveric lividity is said to be distinguished from the effect of injuries inflicted during life by the seat of the discolouration being in the *rete mucosum* and vascular membrane which lie exterior to the true skin" (p. 213). More important still in view of the particular hue alluded to by Dr. O'Neill, "Death from suffocation would be indicated by violet patches on the surface of the body" (p. 220). Continuing upon death from asphyxia, Guy says: "After death the body presents the following appearances. Patches of rosy, bright red, or violet discolouration are seen on the face or on other parts of the body as much on the least as on the most depending parts," &c. (p. 223) And he gives the following warning: "It is most important, however, that the medical jurist should bear in mind that the characteristic appearances of sudden death due primarily to the heart, the lungs, or the brain, are not always equally marked; that they may be combined with each other in different proportions, and that a cause usually productive of the one may, in certain circumstances, give rise to the other" (p. 224). Incidentally, Dr. Guy makes the following statement: "In some instances, as in two cases related by Mr. (afterwards Sir James) Paget, death really due to fatty degeneration of the heart was believed to have been caused by poison" (p. 219). Have we not some reason to surmise that at the present time the number of such instances amounts at least to three? Dr. Guy goes on to say: "The nervous shocks of sufficient force to paralyse the heart and to cause instant and speedy death may be caused by strong and sudden emotions," &c. (p. 219).

Of course, the question arises as to what is the specific cause of the "glimmering blue (or violet) colour" (Guy, p. 458) which the blood assumes in cases of prussic acid poisoning. Is it due to a chemical process (1) during life; or (2) after death? The speed with which the tint appeared in the case narrated by Dr. O'Neill points to its being the result of what we may (not quite ironically) call a vital process. But if it be produced by the action of hydrocyanic acid on the iron in the system we might expect a tint more resembling *prussian blue*. However, I need not further discuss this point.

As to the *fluidity* of the blood found in Whitaker Wright's case allow me to refer to the celebrated John Hunter's "Treatise on the Blood," which I have (bound up with his works on Inflammation and Gunshot Wounds, the volume being published as a new edition in 1828). He says: "In many modes of destroying life the blood is deprived of its power of coagulation, as happens in sudden death produced by many kinds of fits, by anger, electricity or lightning, or by a blow on the stomach, &c. In these cases we find the blood, after death, not only in as fluid a state as in the living vessels, but it does not even coagulate when taken out of them" (p. 32). But more cogent still is the following: "We find in many who die suddenly, from a strong impression of the mind, the blood does not coagulate" (p. 29). I therefore think the sentence in my former letter to which reference has been made is fairly accurate.

The letter of "Midlothian" in THE LANCET of Feb. 20th, p. 540, is very forcible, but I think he is in error in saying we were informed that Whitaker Wright obtained cyanide of potassium in capsules. Dr. Freyberger's theory as to the excoriation of the tongue would be negatived by such information. There is, in fact, no proper evidence that the deceased took poison or that he had poison upon him when he left the court, nor was there anything pointing to poison in the manner of his death as observed by five competent persons. I am, Sirs, yours faithfully,

D. BIDDLE, M.R.C.S. Eng.

Kingston-on-Thames, Feb. 22nd, 1904.

RAYS PROCEEDING FROM ACTIVE MUSCLES AND NERVES.

To the Editors of THE LANCET.

SIRS,—It gives us pleasure to be able to confirm the chief claims of M. Charpentier as to rays given off by active muscles and nerves and we think it only right to publish our results at once in view of the allegations we have heard made that the facts given to the world by the Nancy physicists are mythical. In order that others may verify these results for themselves we will give some details. The experiments are remarkably easy to perform and, to us at least, absolutely convincing as to the actual existence of the rays though we hold no brief for "n" radiation as the cause.

The directions given by M. Charpentier[1] for making the screens should be accurately adhered to. We use hexagonal zinc blende and stick a very thin film on thin paper, a glass slide, &c. Contrary to the general impression we find the effect of the rays seriously diminished by the interposition of a thick background for the fluorescent material. Our best screens are a round patch a centimetre in diameter on very thin celluloid with the zinc sulphide so thinly spread that print can easily be read through it. We excite the screen by holding it near to a source of ultra-violet rays, and let the fluorescent light die away till it has approximately reached the steady stage, then bring underneath it a muscle in a state of contraction, as, for example, the contracting abductor and adductor pollicis of the thumb. The fluorescing screen will then be seen to brighten perceptibly with a rapidity depending on the thickness of the zinc sulphide. One of the most convincing tests is to place a small screen when it is very feebly fluorescing on the floor in a dark room by the side of the foot with the shoe off. It will be invisible by the observer when he is standing upright and he will need to stoop considerably before it becomes visible. If the screen be now placed on the top of the toes and the muscles made active the light will easily be seen and the increase, though considerably diminished, may be observed through the boot. We have tried to estimate the extent of this increase of light and have come to the conclusion it must be fully 100 per cent. when at its best. We arrived at this by measuring the distance at which the spot of light became invisible before the wrist was held behind it and then asking the observer to walk backwards till it again became invisible. These measurements were about five feet without the arm and at least eight feet with it. In addition to observing the effect on the arm the screen was placed over the heart, Broca's convolution, spine, &c. By this means anyone may satisfy himself and those in his company that the light from the screen really does increase, but it is not so easy to prove the matter in print by methods not depending on vision.

The only way that suggested itself to us was to use photography. If the light varied 100 per cent. it should be possible to blacken a negative more or less with it. It doubtless is, but there are difficulties on the way. In the first place the fluorescent film used for judging by vision is only very thinly coated. Secondly, the fluorescence after exposure to light falls rapidly away at first when it is strong and when it arrives at an approximately stable condition is very weak. The negative must therefore be exposed for a long time and this is inconvenient when it must be held over the wrist with the muscles kept at strong tension. We were consequently obliged to coat our screens when used for photography with a thicker film and not wait until the light had fallen to a nearly steady and dull stage Four impressions were taken on one spectrum plate with one-minute exposure and intervals of two and a half minutes between each exposure. Only the first three exposures have left their image, the second being much less black than the first, and the third almost invisible.

On the next negative we took a photograph of the fluorescing screen without the muscle, then another without the muscle, then a third with the muscle behind, all with the same exposure and, of course, the same development. When the negative is examined it will be seen that although the brightness was falling off, the third impression is just about as dark as the second, showing that the fluorescence of the screen had brightened up under the action of the muscle behind it.

It is perhaps necessary to give a word of caution as to the effect of heat on these fluorescent screens. Heat will both originate and add to fluorescence, whereas at present muscle rays have only been proved to augment the effect. As both act in the same way it is, of course, a little difficult to separate the results, but M. Charpentier has made a number of experiments to prove that the increase of light is not due to heat only. For instance, the rays persist when several layers of aluminium or of cardboard separated by layers of air, thus forming a heat screen, are interposed.[2] He also found that a frog which was at a temperature sensibly lower than that of the air in the laboratory formed a good subject. To prove the point on warm-blooded animals he raised the temperature of the screen above that of the animal and found the result the same.[3] Some of these experiments have been confirmed by us. We are now using calcium sulphide for the screens and think it rather better than the zinc. The possibilities of this method of examining the human body are immense, such as, for instance, the localisation of nerve centres in the brain, of injury to peripheral nerves, the size of the heart, &c.

[3] Ibid., Dec. 28th, 1903, p. 1278.

We are, Sirs, yours faithfully,
HUGH WALSHAM, M A., M.D. Cantab., F.R C.P. Lond.
LESLIE MILLER, A.M.I.E E.
Feb 10th, 1904.

*** Our own experiments in THE LANCET Laboratory have confirmed the above observations. Mr. Miller has since pointed out that by simply placing a speck of recently excited calcium sulphide on a thick book—such as, for example, the Medical Directory—a distinct increase in the glow is obvious when the muscles of the hand or leg are contracted underneath.—ED. L.

BILHARZIA HÆMATOBIA.

To the Editors of THE LANCET.

SIRS,—I should be glad to know if there is any treatment otherwise than that of local sedatives for the condition of chronic cystitis and hæmaturia caused by the bilharzia hæmatobia. I take this opportunity of humbly pointing out to the profession the necessity of looking for this trematode in the urine of anyone complaining of bladder or kidney trouble who has lived in the neighbourhood of Rustenburg, Transvaal, for any length of time. My patient has been seen by four medical men, none of whom thought of the true cause of his complaint.

I am, Sirs, yours faithfully,
E. H. WORTH.
Streatham, S.W., Feb. 23rd, 1904.

THE LEGAL AND MEDICAL PROFESSIONS IN IRELAND.

To the Editors of THE LANCET.

SIRS,—The spirit of friendly relationship that formerly existed between the professions of law and medicine and the courtesy that was its natural expression seem to have departed altogether in our times, or to be recalled only by the occasion of social functions outside the sphere of professional work. Anyone who has had experience of the system that presently obtains in the courts cannot fail to have been struck by the unwarranted impertinence—frequently amounting to positive insult—to which medical witnesses are constantly subjected, as if it were a recognised fact that every medical witness must not only be prejudiced but be prepared to sacrifice his professional honour and to degrade his office in the interests of whatever party has employed him.

It is not an infrequent occurrence to find judges priding themselves upon their knowledge of petty medical technicalities and parading it in a series of questions that should certainly arouse indignant protest, if it did not afford compensation in the silent amusement of the doctor who happens to be pilloried in th[illegible] excessive fees and the [illegible] men are occasionally [illegible] to the conclusion that [illegible] of the introductory remarks to the advertisements of patent medicines. The bar, of course, takes its cue from the bench, and the method of cross examination of a medical witness bears frequently a close resemblance to the petty sessions court style where the evidence of a doubtful character is being sifted.

Formerly the cross examination of medical witnesses was directed to minimise the injuries alleged to have taken place, and the most vigorous investigation of facts did not preclude the observance of that old-time courtesy that was honourable alike to both professions. Now, however, the doctor is subjected to every indignity, his motives are impugned, and his testimony is regarded as at least not above suspicion That this is the actual state of things can scarcely be gainsaid, the reason for it may be debateable. It does assuredly seem that the present duty of medical witnesses is to resent immediately and resolutely any insulting observations or insinuations addressed to them in a court of justice, whether they emanate from the judge or the counsel.

I am, Sirs, yours faithfully,
Dublin, Feb. 20th, 1904. E. MAGENNIS, M.D. R.U.I., D P.H.

EXTERNAL STUDENTS OF THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to express in THE LANCET a complaint of external students of the University of London? The preliminary scientific examination for internal students is divided into three parts: (1) chemistry; (2) experimental physics; and (3) biology. If the candidate passes in either of the parts 1, 2, or 3, or in any two of them, he is only required to repeat those parts in which he was unsuccessful. External students, on the other hand, take the examination in two parts: (1) chemistry and experimental physics; and (2) biology. If a candidate is unfortunate enough to fail in chemistry but satisfies the examiners in physics, or *vice versâ*, the whole of the first part must be taken over again. This is obviously hard on the external student, as he has to take the same papers as the internal student. Again, I believe, there is a similar arrangement in the intermediate examination in medicine and yet the internal degree is looked upon as a better degree. In conclusion, may I invite the opinion of external students on these points?—I am, Sirs, yours faithfully,

Feb. 15th, 1904. A SYMPATHISER.

AN EXPERIENCE AMONG THE RED INDIANS.

(FROM A CORRESPONDENT.)

THE following incident which has just come to the knowledge of the writer will illustrate how little those travellers can learn of the life of the people who are carried from one end of Canada to the other in expeditions made in saloon cars on the line of rail, and yet the life of the people is the chief thing that is worth the knowing.

A young Scotchman, well known to the writer, who had grown tired of doing practically nothing in London, made up his mind last summer to try his luck "out West." Accordingly he set out for Canada and in due course found his way to Manitoba. At first he tried the inevitable plan of getting work on a farm but not being satisfied with this set about to look for something more interesting. Being a man of some ability and exactness of method he was offered employment with a survey party which was then going out on a trip northwards. As soon as winter had set in and put a stop to their operations they made ready to return to civilisation. Driving across the frozen prairie in a wagon drawn by several horses (probably a wagon-box on runners), they came to a slough which was frozen over and attempted to cross to avoid a detour. A slough is a hollow or dip in the rolling prairie where water settles in wet seasons but generally not more than some few feet deep and always surrounded by a belt of willow-scrub. When they were half-way across the ice broke and the whole outfit went through into the water. Before they could unhitch the horses two of the animals were drowned, but by dint of extraordinary exertions they managed to get the rest of the horses to drag the wagon out. The men were soaked to the skin, hands and noses were frozen, and then their clothes froze on them as they stood. This, however, is a not uncommon occurrence in a North-West winter.

The young Scotchman now began to have trouble with his left hand, into the palm of which he had happened to drive a nail not long before leaving home, and the wound thereby caused had never satisfactorily healed. Any wound or tender place of this kind is always the first point which the frost will attack. Next day the arm became very painful—possibly there may have been blood poisoning—and began to swell. But there was no assistance at hand and the nearest medical man was 70 miles away, so that there was no alternative but to set out to find him. The young fellow took a horse and rode off, but the suffering was so great that the pain became unendurable. About 30 miles on the way he came to a lodge of Indians encamped on the prairie and being thoroughly exhausted upon seeing a fire in one of the teepees he went in and asked if they would let him sit down and warm himself. A teepee is the Indian tent made of skins sewn together with thongs of hide and

MANCHESTER.

(From our own Correspondent.)

Dangers of Water Gas.

The numerous deaths that have recently taken place from accidentally breathing water gas bring up the question as to the advisability of its use by gas companies merely because it is cheap and can be produced rapidly. The figures are not at hand but statements have been made from time to time that since its very general use for mixing with coal gas accidental poisoning has become more frequent than when coal gas was supplied without admixture. But, as an inquest held at Sheffield on Feb. 17th shows, this is not the only source of danger. A man was found dead in his house. There was nothing in the house to account for it, but close by was a Siemens blast furnace which had been shut down since September until three or four days before the tragedy occurred. Several witnesses told how they visited the house on the Saturday and Sunday, and after being there a few minutes were attacked by headache, dizziness, and vomiting. The post-mortem examination by Dr. Godfrey Carter and the analysis of the blood by Professor Macdonald showed clearly that death was due to poisoning by carbon monoxide. In reply to the coroner, Professor Macdonald said that carbon monoxide was an ordinary product of the Siemens steel process. One-tenth per cent. of the gas had been fatal. The cellar of the house adjoined the works and Dr. H. Scurfield, the medical officer of health, thought that the gas came from the cellar. Several other cases have been recently reported—as, e g., the case of a nun in Liverpool the other day—showing how insidiously dangerous the gas is and, therefore, that special care should be taken against accident. Slight leakage of gas from ordinary gas fittings is a common occurrence. It is bad enough when coal gas only is used but when there is an admixture of water gas the danger to life is enormously intensified and extreme care —a most rare commodity—should be taken to insure that the fittings are gas-proof.

Provident Dispensaries.

The Manchester and Salford Provident Dispensaries Association was formed in 1874 for the double purpose of relieving the various hospitals from improper applications—protecting them, in fact, from abuse—and of affording medical attendance to the provident. The inquiries into the circumstances of the hospital out patients showed that for the first ten weeks after it began more than half of those at the infirmary were "improper applicants" and the percentage at all the associated charities for the year 1875 was 42·32. During the year 1903 the percentage at the four hospitals now associated with the provident dispensaries was 5 05. It appears therefore that the association may fairly lay claim to have done a good deal in the prevention of hospital abuse. As regards the provision of medical attendance on the provident it is not easy to make any statement that would not excite criticism. The medical profession, it is alleged, has never been unanimous about anything and in Manchester the "dispensary doctors" and their position, their wrongs, and their privileges, have afforded material for discussion and controversy for the last 30 years. Nor is the subject yet worn out. The annual report claims an increase in the number of paying members, the total membership being 18,620, while there is a gross surplus of £290, from which certain payments have to be deducted.

Infantile Mortality and the Milk-supply.

On Saturday evening, Feb. 13th, Dr. Henry Ashby addressed a meeting at the Art Museum, Ancoats, on Infantile Mortality. Having pointed out how remarkably the infantile death-rate in New York had declined since systematised attention had been paid by various philanthropic societies, agencies, and individuals to the feeding and environment of children, Dr. Ashby urged that the interests of the farmers, the milk dealers, and the citizens were the same, inasmuch as better results would be obtained if some form of fresh milk were substituted for the condensed milk, and the various forms of dried milk, with additions of malt and starch, which were now used. He urged all to support the corporation in its endeavours to improve the milk supply by insisting on a high standard of cleanliness in its treatment from the cow through its various stages till it reaches the infant and by stopping the supply of impu milk or that from diseased cows.

Infirmary for Leigh.

It has been decided that Leigh, which is now a town between 8000 and 9000 inhabitants, shall have its ow infirmary. The scheme, which is capable of extension, wi provide at first for 30 patients, 15 men and the rest wome and children. The total estimated cost is £15,000. Lor Lilford has given a site in a central situation.

Death of Mr. Robert Smith, M.B., C.M. Aberd., D.P.H.

I regret to record the death of Dr. Robert Smith Rawtenstall, in the Rossendale Valley, where he had a extensive practice. Several weeks ago he suffered fro ptomaine poisoning after eating some tinned tongue. Th was followed by septic pneumonia, from which he neve rallied. His death occurred on Feb. 20th.

Feb. 23rd.

WALES AND WESTERN COUNTIES NOTES

(From our own Correspondents.)

Prevention of Infectious Disease in Bath.

Medical officers of health have to contend with man difficulties in the administration of the Public Health Act more especially in connexion with those sections whic deal with the prevention of infectious disease. It is to b regretted, therefore, that they do not always receive fro their colleagues that support which they are entitled expect. The Bath newspapers have recently containe accounts of disputes which have arisen in the sanitary committee of the corporation between a medical member of th council and the medical officer of health, Dr. W. H. Symons from which it appears that, among other leaflets issued b Dr. Symons, there is one having reference to the preventio of the spread of whooping-cough in which there is given *résumé* of Section 126 of the Public Health Act, 1875, whic imposes a penalty of £5 upon any person who exposes himself if infected, or permits any infected person of whom he in charge to be exposed, in a public place or in a public conveyance. The councillor in question expressed the opinio that Section 126 only applied to those diseases which wer scheduled in the Infectious Disease (Notification) Acts an said it was misleading to state that a fine could be inflicte for allowing a child with whooping-cough to go out in th public streets. The same gentleman also cast some dout upon the desirability of examining bacteriologically spec mens taken from the throats of suspected diphtheri patients because there were so many bacilli very muc alike that they might discover an alarming amount diphtheria. The reputation of the city of Bath as a healt resort would surely be better served if such discussions a these took place in a committee at which reporters were no present.

Bristol Public Baths.

At a meeting of the West of England and South Wale branch of the Incorporated Society of Medical Officers Health held at Bristol on Feb. 18th Dr. D. S. Davies gav an account of the public baths which had been establishe in Bristol and the members of the society subsequentl visited the most recently erected bathing establishment a Barton Hill which has some features of a novel description The corporation of Bristol has acquired by purchase thre public baths and has erected four others. Swimmin baths either open or covered are connected with each o these seven establishments; there are slipper baths in si and in two there are washhouses. The question of erectin three more open swimming baths in the public parks i now under consideration. If these are provided Bristo will compare very favourably with other towns, even wit Liverpool where the accommodation for public bathing i very considerable. The total capital expenditure upon th seven Bristol baths has been nearly £70,000 and in th financial year 1902–03 there were spent in current charge £3300 more than the receipts, a sum equal to about on halfpenny in the pound on the rateable value of the city During the same period there were 267,000 bathers. Th most recently erected baths cost £17 600 and are situate in a densely populated working-class neighbourhood. In th large covered swimming bath the water is heated by th injection of steam; it is kept constantly circulating an while traversing the pipes outside the bath it passes through a mechanical filter of pumice stone. By means of suitable inlets it is also possible to aerate the bath water. But the distinguishing feature of these baths is the installation of spray baths which have been devised by the superintendent, Mr James Kane. These are for washing purposes and are intended to take the place of the ordinary slipper baths. Each spray bath is in a separate cubicle about half the size of an ordinary bathroom and contains in addition to a lavatory basin suitable apparatus for spraying the body. The floor is impervious and slopes to a trapped outlet. Each cubicle is provided with a dressing room from which it is divided by a gangway. This enables Mr. Kane to put into practice his contention that the room in which a bath is taken should be of a higher temperature than the room in which the bather dresses. At the Bristol baths the bath room is heated to a temperature of 115° F. and the dressing room to 65°. In addition to the advantages claimed for a spray bath over a slipper bath, it is said that not only is the initial cost of the spray bath less but there is only one-third of the quantity of water used. The establishment of these baths in a poor neighbourhood is important and the extent to which they are used will be watched with considerable interest.

Royal Devon and Exeter Hospital.

The 167th report of this institution, which has just been issued, states that 1317 in-patients were treated during 1903, against 1349 in 1902. The out-patients numbered 4970, compared with 5214 in the previous year. The average daily number of in-patients was 150. The financial statement shows that the receipts amounted to £7446 and the expenditure to £9122. The committee urgently appeals for increased support, adding that an additional £2000 per annum are needed to carry out the work of the hospital and unless this is forthcoming some of the invested funds of the institution will have to be sold to meet the deficiency. During the year Lieutenant-Colonel Miller presented a handsome marble bust of the late Dr. Patrick Miller who was an honorary physician for nearly 50 years and Mrs. Bankart presented a large photograph of the late Mr. J. Bankart, a former member of the honorary surgical staff.

University College, Bristol.

A deputation of representatives of university colleges, including University College, Bristol, waited on the Chancellor of the Exchequer on Feb. 17th on the subject of the Government grant. The Chancellor intimated in his reply that he was prepared to double the grant for the present year, so that the Bristol College will receive £2400 instead of £1200.

Feb. 23rd

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Medical Society of Edinburgh.

A MEETING of this society was held on Feb. 19th, Dr. D. O. L. Fitzwilliams being in the chair. Dr. Fitzwilliams referred to the great loss sustained by the society and by the Edinburgh Medical School by the recent death of Dr. Robert Milne Murray, an old member of the society. Dr. H. N. Fletcher showed a male patient, aged 57 years, suffering from Nervous Symptoms There had been gradual atrophy of the intrinsic muscles of the right hand and other evidence of progressive muscular atrophy. In addition the patient had lately developed some ataxia, with well-marked Argyll-Robertson pupil, diminution of knee-jerks, and increased sensitiveness to cold, symptoms pointing to locomotor ataxia. The question of diagnosis elicited considerable discussion. Dr. H J Dunbar read notes of four cases of Intussusception recently successfully treated by operation at the Edinburgh Sick Children's Hospital. The children, whose ages varied from six weeks to 11 months, were all boys and all well nourished, healthy children. In two of the cases the invagination had begun, not at the ileo cæcal valve, but in a small pouch in the wall of the cæcum. Dr. Dunbar attributed the success of the operation in these cases very largely to the comparatively short time which had elapsed between the onset of the condition and the operation. The operation itself was one which every practitioner should be prepared to perform. A dissertation on Anæsthesia in Difficult Cases, by Dr. Sidney Gilford, was read in his absence by Dr. H. D. Shepherd. Dr. Gilford contended that chloroform was the safer general anæsthetic at the extremes of life and in all operations on the head, thorax, and abdomen, and also in all cases of lung disease. In other cases ether should as a rule be employed. Deaths under chloroform occurred most frequently in the prime of life, at which time local anæsthesia could be most safely used; and in very many of the recorded cases local anæsthesia could have been perfectly well employed. Dr. Gilford stigmatsied as absolutely criminal the practice occasionally followed, especially in dental operations, of giving chloroform with the patient in the sitting posture.

The Case of Dr. Lachlan Grant.

At a recent meeting of the Ballachulish Workmen's Medical Society, which was held in the Public Hall, Ballachulish, presided over by Mr. Donald Macmillan, it was unanimously agreed that all legal expenses incurred by Dr. Grant and by the medical club during the recent dispute should be paid out of the appeal fund. The fund received upwards of £900 from the public.

Glasgow Southern Medical Society.

Sir J. Halliday Croom on Thursday, Feb. 11th, delivered an interesting address before this society, of which he is Vice-President, taking for his subject "Moot Points in Cancer." The lecturer was inclined to attach little importance to the influence of heredity in malignant disease.

Feb. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ultra-microscopic Disease Germs.

Professor E. J. McWeeney, M.D., delivered an interesting lecture on Feb 17th in the theatre of the Royal Dublin Society on Ultra microscopical Disease Germs. After showing on the optical screen projections of many well known parasites he dealt with the minute bacteria which cause disease through their parasitic mode of life. He showed the large bacteria in anthrax and the smaller kinds down to the germ of influenza which is, of course, one of the smallest known. He then dealt with the special subject of his lecture and stated that the limit of microscopical visibility was set by the wave-length in white light at 1/43500th of an inch. Particles less than half a [illegible] ll blurred spots c[illegible] nor their structu[illegible] amulating evidence to show that certain infectious maladies, the course of which had hitherto baffled the bacteriologist, were really caused by germs too small to be seen by our best microscopes and yet perfectly recognisable by their effects. One of these was the germ of pleuro-pneumonia in cattle, a veritable scourge until about ten years ago when it was stamped out owing to the labours and discoveries of the late Professor Nocard, the very eminent French veterinarian whose latest researches were carried out in Ireland under the auspices of the Agricultural Department. The lecturer explained the methods by which Professor Nocard made his discoveries without any microscopical aid and concluded by mentioning many diseases the pathology of which is really in the domain of the ultra-visible rays. As regards hydrophobia it is well known that the illustrious Pasteur failed to see its germ but, acting in the belief that it must be existent and fatal, saved thousands of lives.

Shell-fish in Ireland.

Dr. T. J Browne, medical inspector under the Local Government Board, states that periwinkles are collected all round the coast of Ireland to the measure of about 1500 tons per year and are exported to the London, Liverpool, and Manchester markets. For some strange reason they are not consumed in Ireland as food The inspector states that they are not collected in the vicinity of sewer outfalls or in situations liable to pollution. They are boiled before being eaten but Dr. Browne seems doubtful whether they are sufficiently cooked to be safe from pathogenic organisms. He is unable to say whether they are completely sterilised but is of opinion that if they are not properly cooked their consumption might be attended with a certain amount of risk.

Epidemic of Blood-poisoning in Cootehill Workhouse.

Dr. E. Cooy Bigger, medical inspector under the Local

Government Board, has reported in reference to the recent outbreak of septicæmia in the infirmary of Cootehill Workhouse which caused the death of four patients that he found as a result of his investigation that the patients were in charge of two qualified nurses who were present and assisted at the operations. The medical officer sterilised his instruments and dressings and the operations were carried out with the necessary antiseptic precautions. The wards were disinfected biennially. No sanitary arrangements were provided inside the building and drainage and slops were carried off in an open channel situated several feet from the walls. The wards had not sufficient window space and so did not receive sufficient sunlight. A direct and definite cause for the outbreak was difficult to assign but Dr. Bigger reports that the two main wards occupied by patients were re floored some years ago and that the boards, which were not closely joined, were laid on the top of the old floor, which might have contained disease germs. The medical officer was inclined to attribute the outbreak to this circumstance. It has been advised by the Local Government Board that the fever hospital should be enlarged and that better accommodation should be provided for all infirmary patients.

Queen's College, Belfast, and the Ulster Medical Society.

The Ulster Medical Society at a recent general meeting unanimously passed an important resolution having reference to Queen's College, Belfast. The resolution recorded the necessity for the provision of increased facilities for higher scientific teaching in Queen's College, pointing out that the faculty of medicine had always formed one of the most important departments of the College and must ever remain in the closest touch with the progress of investigation and research in the various physical and biological sciences. The resolution also, while recognising and appreciating the manner in which Queen's College had utilised the resources at its disposal in keeping abreast of modern methods of teaching medical science, pointed out that the training of medical students in the subjects of zoology, botany, chemistry, and physics is certain to suffer unless more adequate facilities for teaching these subjects are now provided and drew attention to the necessity for providing the College with the means of taking full advantage of the generous offer of the Right Hon. W. J. Pirrie to build a laboratory for physical science at his own expense. It is undoubted that the absence of sufficient laboratory accommodation and staff seriously interferes with the development of post graduate work in medical science at Queen's College and it is to be hoped the Lord Lieutenant, the Chief Secretary, Lord Londonderry, and the various Members of Parliament to whom copies of the motion have been sent, will take an active interest in the plight of the College.

Feb. 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Diagnosis of Actinomycosis.

AT the meeting of the Academy of Medicine held on Feb. 9th M. Le Dentu referred to the difficulties in the diagnosis of actinomycosis and to the necessity which existed for a histological examination. He himself had just had under his own care a very interesting and deceptive case—namely, that of an old man, aged 75 years, who was suffering from a tumour. The look of the growth and the multiple fistulæ in it led the medical men of Lyons to think that the case was one of actinomycosis. Examination of the pus, however, revealed none of the typical granules, neither did curetting the bone. Histological examination showed the growth to be a typical epithelioma. M. Cornil referred to the possible absence of the characteristic granules. In one case under his care these granules which could not be found at the first examination were afterwards discovered in large quantities in the spongy nodules from the bone. This, however, is by no means always so even in marked cases of actinomycosis. The ray masses, easily stained by violet, are as characteristic as the granules for purposes of diagnosis. On the whole, however, the opinion was expressed that it is impossible to make a diagnosis in actinomycosis without a histological examination.

The Causes of Congenital Dislocation of the Hip joint.

Congenital dislocation of the hip-joint, a fairly common condition and one the explanation of which has often puzzled the medical profession, formed the subject of another communication at the same sitting of the Academy of Medicine. M. Le Damany, professor at the Rennes School of Medicine, brought forward a theory based upon anthropological considerations. On the one hand, the upright position by bringing about a twisting of the femur and, on the other hand, the large size of the head due to the development of the brain with its concomitant development of the pelvis would be the predisposing causes of this dislocation, which is altogether proper to the human species. Owing to the obliquity of the walls of the pelvis the head of the femur, being pushed forward by the twisting of the bone, has a tendency to slip out of the acetabular cavity. As a matter of fact, in those persons who are the subjects of this lesion, either at the time of birth or in whom it develops at a very early age, the observer may note an exaggeration of the normal twist of the femur and an excessive obliquity of the base of the acetabular cavity.

Inspection of the Paris Hospitals.

The authorities of the Assistance Publique have been reckoning up the wastage which occurs in the hospitals of Paris and M. Mesureur has sent to all the hospital directors a circular announcing that he has inaugurated a system of inspection for looking into the expenses of these establishments. Each of the inspectors, who are nine in number, will spend ten days in one of the hospitals to which they will be allotted by the director of the Assistance Publique. At the end of this time they will send in a report upon the working of the hospital, mentioning any particular points which may have struck them. They will, of course, take particular notice of financial extravagances as well as of errors of administration.

Presentation to Professor Bouchard.

On Feb. 21st the ceremony took place at the Academy of Medicine of the presentation of a medal to Professor Bouchard which had been subscribed for by his pupils and friends. Speeches were delivered by, amongst others, Professor Debove, dean of the Faculty of Medicine, M. Liard, the vice rector of the Academy of Paris, and the Minister of Public Instruction who presided. The last named in the course of his speech reminded his audience of the tact and prudence, the farsightedness and goodwill which Professor Bouchard had displayed throughout his career, particularly as regarded the inspections in the faculties of medicine with which he had been charged. Knowing well how to recognise intuitively and to encourage good intentions and how to give timely counsel in such a form that it would be well received Professor Bouchard had been a brilliant representative of French science in foreign countries at various congresses. Only last year he had presided over a congress at Cairo where he had gained the respect and sympathy of all. His luminous and sound opinion together with his accurate and precise speeches had many a time been the determining factor in a decision. The Minister concluded by joining his congratulations to those of the pupils and friends of the master. Professor Bouchard, who laboured under obvious emotion, spoke a few words which were almost inaudible owing to the cheering.

Feb. 23rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Administration of the Holy Communion.

IN the present age even those rites of the Church which the devout regard as being above question or criticism are liable to be scrutinised from the hygienic point of view. The communion cup, for instance, has been looked upon as endangering the bodily health of communicants owing to the risk of disease being conveyed by it and some reformers have therefore proposed to replace the general communion cup by cups belonging to each individual communicant. The subject has been discussed at the last General Synod of the Protestant Church of Prussia but the matter was adjourned The daily papers now state that the vestry of St. Nicolas in Berlin, after hearing an address by the archdeacon, has decided to provide 40 communion cups to be used in taking the sacrament and also to permit any communicant to bring his own cup with him. For those who object to this innovation a cup in common will be provided as hitherto, so that the wishes of all parties, whether belonging to the new school or the old, may be met.

Medical Questions before the Berlin Town Council.

Medical questions were a prominent feature at the recent meetings of the Berlin town council. One of them had reference to the accommodation for venereal patients in the hospitals. This is far from being satisfactory and the attention of the municipal authorities has been drawn to the matter by some unfortunate occurrences which have been recently reported in the daily press. Some years ago there was only one special department for venereal patients—namely, in the Royal Charité Hospital. The female patients were almost exclusively registered prostitutes admitted by order of the police medical officer. In consequence of the increasing number of prostitutes the available beds in course of time were found to be too few and so in 1890 the municipal authorities enlarged the accommodation by establishing a venereal department in connexion with the Municipal Asylum for the Poor. This department, which at first had 60 beds and at present has 200 beds and is under the charge of Professor Behrend, is now insufficient for the patients seeking admission. Some of the female patients complained of their enforced association with the prostitutes sent in by the police and in consequence of this want of classification many women when suffering from venereal diseases preferred to be treated at home rather than to enter the venereal department of the asylum or the Charité Hospital, the result being the extension of such diseases in families. The municipal authorities therefore intend to establish a special hospital for prostitutes exclusively and to abolish the venereal department of the asylum. For male patients and for females who are not prostitutes a special department will be provided in the new Rudolf Virchow Hospital, the largest and most lavishly equipped hospital in Berlin, which is to be opened within two years. At the last meeting of the council, when the municipal authorities were sharply attacked because they had allowed matters to become so unsatisfactory, it was decided that in the meantime a department for syphilitic patients should be provided in one of the existing municipal hospitals by erecting temporary pavilions. Other subjects of discussion concerned the enlargement of the Kaiserin Friedrich Hospital for Children, where the number of beds, especially for children with contagious diseases, has proved to be insufficient. Some of the members were of opinion that the establishment of several small hospitals for children in various districts of the city would be preferable but as this scheme would require several years for carrying it out the council decided to enlarge the existing hospital. A third matter of importance was the establishment of a training school for nurses exclusively for the municipal hospitals. Hitherto the nurses of these hospitals have belonged to certain corporations—some of them religious and some of them secular—which were under a contract to provide a sufficient number of nurses, the municipality paying a certain sum to the corporation. Henceforth the municipal council will have its own nurses trained free of charge for one year in the municipal training school, the condition being made that the probationers shall serve three years as nurses in the municipal hospitals. The nurses will be paid from 360 to 540 marks (from £18 to £27) per annum and the matrons will have salaries varying from 1200 to 1800 marks; they will also have free board, residence, and wearing apparel. They will be entitled to pensions in the event of incapacity from age or ill health. A great number of candidates have already applied for admission to the training school which is to be in connexion with the Moabit Hospital.

Professor Koch.

It is rumoured that Professor Koch intends to resign his appointment as chief of the Royal Institution for Infectious Disease and to settle in South Africa. This conjecture no doubt originated in connexion with the repeated and prolonged visits which he has made to Cape Colony and the other British colonies in Africa on the invitation of the Colonial Governments. I learn, however, from a trustworthy source that the rumour in question is unfounded, that Professor Koch has gone to South Africa by special permission of the Emperor, and that his place at the above institution will be preserved for him till his return. It is true that Professor Koch has no objection to be absent from Berlin, his relations with the medical faculty there not being very cordial for reasons which are of a personal rather than of a professional character and are not of recent date. If he contemplates retirement it is certain that nothing will be decided till his return, which is announced for the end of April.

Appointments.

Two new appointments of ordinary professors in the Berlin medical faculty are announced. The chair of the late Professor Jolly will be taken by Professor Ziehen of Halle, whilst Professor Gusserow, who is retiring from the chair of Gynæcology on the ground of his advanced age, will be succeeded by Professor Bumm, also of Halle.

Changes in the Ontario Board of Health.

Dr. Peter H. Bryce, who for many years has been secretary of the Ontario Board of Health and deputy registrar-general, has entered the service of the Dominion Government at Ottawa, his new office being that of immigration inspector, supervising all the immigration officers at the ports of entry. In addition to this he is to have charge of the sanitary arrangements in connexion with the Indians who are the wards of the Federal Government. Dr. Bryce has been succeeded by Dr. Charles A. Hodgetts who has been connected with the board of health for a number of years, having three years ago been appointed permanently to the position of medical inspector of the province of Ontario.

Vital Statistics of Ontario.

The annual report of the Registrar General for the province of Ontario is now being prepared for 1902. During that year there were 47,796 births registered, compared with 46,061 in the previous year, an increase of 1735, giving a general birth-rate of 21 7 per 1000. The birth rate in the cities is 22 2 per 1000, or 0 5 higher than the general average. Compared with the 1 per cent. increase in population the increase in births is fairly satisfactory. Comparison with the province of Quebec, so long regarded as the possessor of a high [illegible] ecrease in [illegible] in 1898 to [illegible] the same [illegible] numbered 18,072, [illegible] of 37. The total [illegible] ith 29,608 in 1901, giving a death-rate of 12 6 per 1000 compared with 13·6 per 1000 in 1901. The high average of health in Ontario is shown by comparison with other countries, the corresponding rate being 17 1 in the United Kingdom, 14·9 in Norway, 24 2 in Austria, 18 0 in Switzerland, 20 0 in the German Empire, 20 1 in France, and 27 6 in Spain. The deaths from typhoid fever and from tuberculosis show a continued decrease.

Prevention of Tuberculosis.

The British Columbia Association for the Prevention and Treatment of Consumption and other Forms of Tuberculosis was organised at a meeting held in the City Hall, Victoria, British Columbia, on Jan. 20th. The medical aspects of the question were put before the meeting by Dr. C. J. Fagan, the secretary of the Provincial Board of Health, who thought that the Dominion Government should assist more in the way of prevention of the disease, seeing that Canada spends annually some $500,000 to assist 60,000 emigrants to settle here. Sir Henry Joly, the Lieutenant Governor of the province, was elected honorary president; Dr. Proctor of Kamloops, secretary; Dr. Fagan, treasurer; and Mr. R E. Walker and Dr. J. C. Davie members of the executive committee.

Royal Victoria Hospital, Montreal.

The annual meeting of the board of governors of the Royal Victoria Hospital, Montreal, was held in that city in the latter part of January, the medical report being as follows. On Jan. 1st, 1903, there were 188 patients remaining over from 1902. During the year 2911 were discharged, of whom 1397 were well, 914 improved, 165 not improved, 293 not treated, and 142 died. Of the 142 deaths 38 took place within 48 hours of admission. The death-rate for the year has been 4 88 per cent., or if those dying within 48 hours of their admission be deducted 3·57 per cent. The highest number of patients in the hospital on any one day was 230 on Dec. 17th and the lowest was 166 on August 30th. In the out-patient department the total number of patients treated was 4398. The income for the year amounted to $140,368, while the ordinary expenditure amounted to $120 419. The number of patients admitted during the year numbered 2931.

National Sanatorium Association: Sixth Annual Report.

The sixth annual report of the physician in charge of the Muskoka Cottage Sanatorium shows that the past official year ending Sept. 30th, 1903, has been one of progress. The greatest number of patients in residence at any one time during previous years has been 61; last year they reached 69. The number of patients in the sanatorium on Oct. 1st, 1902, was 49—namely, 26 males and 23 females. The number admitted during the year was 164—namely, 99 males and 65 females. Of 115 patients whose cases were reported on 24 were discharged apparently cured and 41 with disease arrested.

Death of Dr. John Herbert Sangster.

A notable figure in the medical life of the province of Ontario passed away in the person of Dr. John Herbert Sangster of Port Perry, Ontario, who died suddenly from heart disease while on a visit to Toronto. He was 72 years of age and was born in London, England. From 1866 until 1871 he was a prominent authority on education in Ontario, being at that time principal of the Toronto Normal School, at the same time acting as professor of chemistry and botany at what was then Dr. Rolph's medical school which subsequently became the Medical Faculty of Victoria, now defunct. It was at that time that he took up the study of medicine and upon his retirement from the Normal School he removed to Chicago, but returning within a short time to Canada he began the active practice of his profession at Port Perry, where he continued up to the time of his death. He was a prominent and valued member of the Ontario Medical Council, to which body he was elected in 1894. Here, upon taking his seat, he began a campaign against the presence on that body of representatives from defunct medical colleges. Many years ago Sangster's Arithmetic was the standard text-book in the public schools.

Western General Hospital, Montreal.

The annual meeting of the supporters of the Western General Hospital, Montreal, was held in January when it was reported that the number of patients in the institution was larger than ever before. The medical report was submitted by Dr. F. R England. It is stated that the number of patients admitted to the hospital during 1903 was 600. The death-rate was 5·16 per cent., but deducting the deaths which occurred within 48 hours of their admission and which numbered 13 the rate dropped to 3 per cent. The average number of days' treatment in the hospital was 18·3. In the outdoor department the number treated amounted to 7560, or an increase of 990 over the previous year.

Protestant Hospital for the Insane, Quebec.

The annual meeting of the supporters of the Protestant Hospital for the Insane of Quebec, situated at Verdun, was held at Montreal in February. A question which caused a good deal of discussion was that of voluntary commitment, the superintendent, Dr. T. W. Burgess explaining that he had been solicited by people who believed they would be mentally benefited by treatment in the institution for admission. Owing to the law which forbids this form of commitment he was, of course, obliged to refuse their requests. The total admissions for the year numbered 152 and the number under treatment 581; 57 were discharged as recovered and 23 as improved. The deaths numbered 44.

Canadian Medical Association.

The thirty-seventh annual meeting of the Canadian Medical Association will meet this year at the extreme western end of Canada, at Vancouver, British Columbia, under the presidency of Dr. Simon J. Tunstall of that city. Mr. Mayo Robson will be a guest of the association.

Toronto, Feb. 17th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Asylums for the Insane in New York State.

THE eleventh annual report of the New York State Charities Aid Association to the State Commission in Lunacy has just been published. The report states that for the year 1903 the total number of insane persons in State hospitals and licensed asylums was 25,934, an increase of 941 over the previous year. Of this total number, 24,187 patients were in the 14 State hospitals, being 918 more than on Oct. 1st, 1902. This increase is much larger than has been customary. One of the most important measures noticed in the report was the Bill introduced in the New York State Legislature of 1903 to provide for the establishment of a reception hospital for the insane through the joint action of the State and the city of New York. This Bill authorised the city to acquire a suitable site and to lease it to the State at a nominal consideration and authorised the State to spend $300,000 (£60,000) in erecting buildings to receive "a limited number of alleged insane and insane patients for the purpose of affording them such speedy and skilled treatment as might be conducive to their more prompt recovery" The annual per capita rate of maintenance for inmates of the public asylums for the insane in New York State showed an increase of nearly $11 (£2 4s) over the rate of the previous year. All the State hospitals of New York are greatly overcrowded and it is recommended in the report that steps should be taken quickly to provide for the accommodation of the rapidly increasing insane population of New York State.

Bellevue Hospital Nurses' Home.

The Bellevue Training School for Nurses, the first of its kind started in the United States, has issued an appeal for aid. Nearly 30 years ago the Bellevue Training School practically came into existence, since which time the work performed by those trained there has been of an exceptional nature. The city of New York pays to the Bellevue Training School a certain sum for the services and maintenance of each nurse supplied, but this sum is not enough to cover the entire cost of educating and caring for these women. The crowded condition of the wards of Bellevue Hospital makes it necessary now for each nurse to care, on an average, for 7·5 patients, while the average of nurses to patients in the best hospitals in the United States not run by cities is 4·9. The city of New York now requires more nurses. To answer this call adequately more room is needed for the Nurses' Home. The present home is filled to its utmost capacity and additional premises must be at once rented and properly equipped. The limit of the private income of the home has been reached and as new arrangements must be made at once the sum of $25,000 (£5000) is asked for to make it possible to embark upon this work. This is the first public appeal made by the Bellevue Training School for Nurses in over a quarter of a century.

Feb. 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Preservatives in Food.

AT the central court, Sydney, an employé of the Concentrated Milk Company was prosecuted for "disposing of a certain article of food—to wit, concentrated milk—containing boric acid, an antiseptic mentioned in the Public Health Regulations, in a proportion exceeding $\frac{1}{100}$th of a grain per pint of the said food." The Government analyst notified that the milk in question contained 14 grains per pint of boric acid, an amount that would be dangerous to health. The case was adjourned.

Duties of Health Officers.

Codes of duties for officers of health under the Health Acts have been issued by the Board of Health of Victoria as follows:—

An officer of health is required to carry out the directions of the board or municipal council and to inform himself respecting all influences injurious to health in the municipal district for which he is appointed. On becoming aware that any person in the district is affected with small-pox, Asiatic cholera, plague, yellow fever, typhus fever or leprosy, or that any article is likely to convey the infection of any such diseases he must [illegible] report the matter to the board and the municipal clerk. S[illegible]fer to a district other than that for which h[illegible]ition to report still holds good. The officer is obliged to investigate any disease of a dangerous nature not included in the above list, also as to any condition injurious to health and to advise as to the closing of schools and superintend the work of inspectors. Another of his duties is to systematically inspect premises used for the production, preparation, storage, or sale of articles of food. In case any article appears to be unfit for human consumption he is to give such directions as may be necessary to have it dealt with according to statute. The officer is obliged to direct inspectors to procure samples of drugs for analysis and must inquire into all offensive processes of trade and maintain careful supervision over water works, drainage, and sewerage. Duties performed by the officers are to be recorded and embodied in an annual report to the council and the board.

Consumptives' Home, South Australia.

The Governor of South Australia has opened the "Gooch" wing recently added to the Kalyra Home for Consumptives at Belair, South Australia. The home is pleasantly situated at the top of the first range of the Mount Lofty Hills. The new wing has been erected chiefly by the efforts of Mr. C. H. Gooch, after whom it is named.

Dismissal of a Hospital Surgeon.

The surgeon to the Junee Hospital, New South Wales, has, according to the *Cootamundra Herald*, been dismissed by the committee in somewhat peculiar circumstances. A maid-servant in his employ was admitted to the hospital and there confined; a few hours afterwards she was removed to the surgeon's private house. She then left his house and went by train to Albury and was admitted to the Albury Hospital in a state of collapse. It is stated that the surgeon in question knew nothing of her condition till after her confinement and had her taken back to his house in the interests of her family to avoid publicity and that "not the slightest suspicion of impropriety rests on" him.

Dental Board, New South Wales.

The first election of members of the Dental Board under the Dentists Act of New South Wales resulted in the return of Sir James Graham, M.D., and Dr. Palmer as medical members.

Balmain Friendly Societies' Dispensary.

The trouble between the Australian Natives' Association and the medical officers to the Balmain Dispensary has resulted in a proposal by the members of the dispensary board to appoint three medical officers, one at £600 and two at £500 per annum, to give their whole time to the members of the dispensary and of the affiliated lodges. The question is whether they will be able to get the medical officers who would be ostracised by their professional brethren.

Brunswick Friendly Societies' Dispensary.

At Brunswick, Victoria, the lodges formed a medical institute and have with great difficulty secured two medical officers. How long they will be able to carry on is doubtful as they are not recognised by the rest of the profession.

Sydney Medical Mission.

The third annual meeting of the supporters of the Sydney Medical Mission was held recently, Lady Rawson presiding. The report showed that the medical superintendent had made 2195 visits to the homes of 495 patients; 2644 patients had made 10,309 attendances at the dispensary. The mission reaches a class unable to attend the hospitals during the day time as they either have to be at work or are women who cannot leave their homes. All the patients were extremely poor. At the meeting the speakers all expressed surprise at the amount of work done and the smallness of the expenditure, and extolled the great self-sacrifice of the medical superintendent, Dr Carlile Thomas, who has been now succeeded by Dr. Stillwell.

Acute Suffocative Pulmonary Œdema.

In the *Intercolonial Medical Journal* for December Mr. H. M. Hewlett describes four cases of a very rare condition—acute suffocative pulmonary œdema—concerning which very little information can be found. The cases are most carefully recorded, with details of the chemical examination of the expectorated fluid and of the blood pressure, and in one fatal case of the post-mortem examination. All the cases occurred in women at or past the prime of life; all showed evidence of chronic cardio vascular and renal disease with very great arterial systolic blood pressure, produced probably by excessive consumption of alcohol. The majority of the attacks occurred at night after some extra exertion. They came on with remarkable suddenness and subsided rapidly when improvement began. The expectoration began immediately and, in Mr Hewlett's opinion, the mechanical obstruction which it causes to the air entry is responsible for the dyspnœa, cyanosis, and laboured heart action. Professor Martin has suggested that the escape of the highly albuminous fluid is due to an altered permeability of the capillaries and alveolar cells; it cannot be a question of increased pressure, for no ordinary pressure would drive almost pure serum through living animal membranes in their normal condition. The treatment which Mr. Hewlett has found effective is the hypodermic injection of a quarter of a grain of morphine.

Jan. 12th.

Obituary.

JAMES SMITH TURNER, M.R.C.S. ENG., L.D.S.

ON Feb. 22nd, after a long illness, Mr. James Smith Turner passed away at his residence in Ealing. He was for many years one of the most notable members of the dental profession and to him perhaps more than to any other man dentistry owes the position which it holds at the present day. He was one of the pioneers of dental reform and with the late Sir John Tomes was primarily responsible for the passing of the Dentists Act in 1878. Born in Edinburgh in 1832 James Smith Turner was at the age of 14 years apprenticed as a mechanic to a dentist in that city. In 1853 he came to London without money or influence and in a short space of time was destined to see two important events occur—the passing of the Medical Act of 1858 which gave to the Royal College of Surgeons powers to grant licences in dental surgery, and the establishment of the Dental Hospital. He joined the Middlesex and the Dental Hospitals, and in May, 1863, became M.R.C.S. and in the following August L.D.S., supporting himself all the time by mechanical work and a growing dental practice. It was during his career at the Middlesex Hospital that he became associated with Mr. (subsequently Sir) John Tomes, and those two ardent reformers with several colleagues set to work to convert what was then the trade of a dentist into an honourable profession. In 1872 he went to the United States to study the conditions of dentistry in that country and on his return the campaign for dental reform was started in true earnestness. The movement met with hostility in some medical quarters but in spite of this a Bill was drawn up and thanks to the labours of Lord Avebury (then Sir John Lubbock) the Act was passed in one session. In the lobby of the House Mr. Smith Turner was indefatigable in his attendance, being always present to answer inquiries and to remove difficulties and there is little doubt that but for his splendid self-sacrifice the Bill would not have so speedily become law. Directly the Act was passed he set to work to found the British Dental Association and was for many years president of the representative board and in 1891 presided at the annual meeting of the association in London, when he delivered a thoughtful and masterly address. In the Royal Dental Hospital he was ever deeply interested and held the position for several years of lecturer on dental mechanics and at the time of his death was one of the consulting dental surgeons and vice-chairman of the committee of management.

At the Middlesex Hospital he held the posts of dental surgeon and consulting dental surgeon. He was for years an active member of the Odontological Society of Great Britain and held office continuously from 1873 to 1884 when he was elected president. A friend closely associated with him for nearly 20 years in professional matters writes that "a very short acquaintance convinced me of his intense devotion to the highest professional interests. His professional instincts were of the highest order and everything that even had the suspicion of loose ethics received from him strenuous and untiring opposition. This integrity of purpose naturally brought him into conflict with those in his profession who had hardly risen from the trade position from which dentistry had only just emerged and consequently his motives were often not [illegible] appreciated." Mr. Smith Turner was a man [illegible] and [illegible] able application. He was an [illegible] to hold his own in any discussion, and though a born fighter he never carried his hostility into private life. A true and loyal friend, an honourable and upright man, all his innate instincts were professional and he was always ready to sacrifice time and pleasure to the good of the profession which he loved so well. Ill though he was he followed with the closest attention the agitation about university degrees in dentistry and some of his last words sent to one of his closest friends who disagreed with their establishment were "Stick to your guns!" He died early on Monday morning and on the Sunday afternoon he had listened with the closest interest to the article in THE LANCET of Feb. 20th on the Future Position of the Dental Profession. He said "things have changed" and he had lived to see the change for which he had given up professional practice and the pleasures of domestic life.

GEORGE NIVEN, M.A. ABERD., M.B. CANTAB., M.R C.S. ENG.

THE death occurred on Feb. 7th of Dr. G. Niven of Manchester at the age of 45 years. The deceased, who originally belonged to Peterhead, had a very distinguished career as a student at Aberdeen, where he took the degree of M.A. in 1877, and at Cambridge, where he took the degrees of B.A. in 1881 and M.B. in 1886; also in the latter year he obtained the diploma of M.R.C.S. Eng. On the completion of his university studies he entered upon professional work at Didsbury, Manchester, where he not only built up a large practice but came to be known in medical circles as one of the ablest practitioners of the time. Dr. Niven married the eldest daughter of Mrs. Knox, St. Ann's, Inverugie, Peterhead, and she and three children survive him. Sincere and widespread regret will be felt at the early death of so promising a practitioner. One of the brothers of the deceased is Sir William Niven, for many years director of studies in the Royal Naval College, Greenwich; another brother is Mr. Charles Niven, professor of natural philosophy in the University of Aberdeen; while a third brother has attained a high position in the medical profession at Manchester.

CHARLES GODSON, F.R.C.S. ENG., L.S.A.

DEATH has just removed from our ranks one of the kindest hearted and most genial of general practitioners, a man whom all other medical men living within seven miles of Barnet respected and whose opinion was highly valued, not only by his own patients, but also by his fellow practitioners who called him in to assist them in the diagnosis and management of doubtful cases. Mr. Godson was 84 years of age and although he was little known to those in active practice at the present time, having retired from the profession about 20 years ago to enjoy a well-earned rest and to lead the life of a country gentleman, he was in his day highly thought of by Gull, Paget, Erichsen, Pollock, and other shining lights of bygone days.

Born in June, 1819, at Heckington, in Lincolnshire, he was apprenticed for the sum of £294 for a term of five years in 1834 to Mr. William Wade of the Westminster Dispensary, Gerrard-street, Soho, for the purpose, as stated in the words of his indenture, of being "instructed in the arts, businesses, or professions of a Surgeon, Apothecary, Accoucheur, or Man Midwife," and he was "to be allowed good and sufficient meat and drink at the table of the said William Wade." During this time he dissected and attended the lectures and practice at his own dispensary and also at St. George's Hospital. He became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries in 1840 and 20 years later he was elected an honorary Fellow of the Royal College of Surgeons. In 1842 he married and he also bought Mr. Morison's practice at Barnet and while there he held various appointments, among which may be mentioned that of surgeon to the 2nd Middlesex Royal Rifle Regiment of Militia, divisional surgeon to the Metropolitan Police, and surgeon to the Great Northern Railway and to the Leathersellers' Company. He was also medical officer to the Barnet union infirmary and a Fellow of the Medical Society and of the Obstetrical Society of London. His memory will always be held dear by those who knew him.

In Vol. XVIII. of the Transactions of the Obstetrical Society of London (1877) will be found "Midwifery Statistics of 35 Years' Practice, compiled by Clement Godson, M.D., from the records of his father, Charles Godson, F.R.C.S.," the result of which showed the death-rate to be as low as 1 in every 460 women confined, or seven deaths in 35 years' practice, 3223 women having been attended. The paper shows how carefully the details of each case were recorded and how satisfactory were the results.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Charles F. France, M R.C.S. Eng., L R C.P. Lond., was on Feb. 18th presented with a meerschaum pipe, a silver match-box (suitably inscribed), and tobacco by the members of the St. Thomas's ambulance class of Wigan as a token of appreciation of his services.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the first examination of the Board at the quarterly meeting of the examiners in the subjects indicated:—

Chemistry.—Joseph Henderson Bulcock, Owens College, Manchester, and Technical School, Blackburn; John Head Burdett, St. Mary's Hospital; William Burton, University of Liverpool and Technical School, Liverpool; Henry Carter, Birkbeck Institution; Henry Robert Cotton and Arthur Downes, St. Bartholomew's Hospital; Cecil Howard Douglas, Guy's Hospital; Arthur Edwin Foerster and José Leighton Houlton, M.P.S., St. George's Hospital; Charles Richard Gardner, Westminster Hospital; John Rhodes Liddell, University College, Sheffield; Arnold da Vesci Gibson and John Harry Meers, St. Mary's Hospital; Thomas Mackinlay Miller, St. Bartholomew's Hospital; Cyril Macdonald Plumptre, Guy's Hospital; Gerald Henry Pridham, St. Thomas's Hospital; Edward John Joseph Quirk, Charing Cross Hospital; Alfred Henry Valentine St. John, Guy's Hospital; Thornley Fretson Skinner, University College, Sheffield; John Startin, St. Thomas's Hospital; Frank Stuart Tamplin, St. George's Hospital; Harold Skarratt Thomas, London Hospital; and Alfred Richardson Wise, Birkbeck Institution.

Practical Pharmacy.—Cecil Crees Austen, Westminster Hospital; Arthur Reginald Beaumont, L.D.S. Eng., Laurence Henry Burner, and George Hammond Cheyney, Guy's Hospital; William Byam, St. George's Hospital; Emil Christofferson, William Thomas Clarke, and Edward James Dermott, University College, Bristol; Howard Dennis Clapham, private study; James Edward Collins, London and Guy's Hospitals; [illegible] Courtney, St. George's Hospital; Her [illegible] University College, Sheffield; Verner G [illegible] holomew's Hospital; James Aubrey Irel [illegible] ol; James Eaton Lascelles, St. Mary's Hospital; Walter Lister, St. George's Hospital and Yorkshire College, Leeds; Alexander Henry McCandlish and George Richard Painton, London Hospital; Herbert Alban Parker, Christopher Trehane Pellow, and Harold Sigismund Sington, St. Thomas's Hospital; James Sydney Pascoe, Charing Cross Hospital; Martin Remers, Owens College, Manchester; Walter Duckett Southern, private study; Maurice Spotswood, University of Liverpool; James Leonard Octavius Tilley, L.D.S. Eng., University College, Bristol, and Charing Cross Hospital; William Tregea and Horace Welshman Ward, Birmingham University; and William Charles Augustus Ward, St. Thomas's Hospital.

Elementary Biology.—Harold Percivall Aubrey, L D.S. Eng., Birkbeck Institution; Herbert George Balls, Middlesex Hospital; Francis Brachi, St. George's Hospital; Ernest Frederic Westmore Buckell, University College Hospital; Henry Carter, Birkbeck Institution; Cecil Howard Douglas, Guy's Hospital; Bertie Cecil Eskell, Merchant Venturers' Technical College, Bristol; George Douglas Gordon Fergusson, St. Mary's Hospital; Arthur Edwin Foerster and José Leighton Houlton, M.P.S., St. George's Hospital; Howell Woodwell Gabe, Middlesex Hospital; Herbert Wilks Heasman, Edward Pierce Llewellyn Hughes, and Victor Patrick [illegible] Toase Jackson, L D.S. E [illegible] k Institution; George L [illegible] ospital; Henry Goff Kil [illegible] esex Hospital; John Rh [illegible] ield; Reginald Arthur [illegible] n Mozumder, St. Bart [illegible] s, Guy's Hospital; Pe [illegible] chard Bancroft Nevel Re [illegible] ls and Arthur Denys R [illegible] el, University College, Cardiff.

The following gentlemen passed the second examination of the Board at the quarterly meeting of the examiners in the subjects indicated:—

Anatomy [illegible] irch, Owens College, Manchester; Walter [illegible] Camb., Cambridge University and St. Geo [illegible] Rowley Bristow and Gustavus William [illegible] Thomas's Hospital; Bevil Molesworth Collard, London Hospital; John Frederic Cutler, Guy's Hospital; Francis Carminon Doble, King's College Hospital; Herbert James Duské, St. Mary's Hospital; Leonard Edwards and Carlton Atkinson Ellis, London Hospital; John Stewart Farnfield, L.D.S. Eng., Guy's Hospital; Rupert Farrant, Westminster Hospital; John Rowland Foster [illegible] College Hospital; [illegible] King's Philip Julius Franklin, Univer [illegible] Philip College Hospital; Edward Slade [illegible] omew's Henry George Gosse and Henry [illegible] Hospital; William Robert Greening, Guy's Hospital; Robert Eugene Vaughan Hale, B A. Camb., Cambridge University and St. Andrews University; Arthur William Hayward, B.A. Camb., and Carl Cornelius Hickey, Westminster Hospital; Reginald Beaumont Heygate, Middlesex Hospital; Cyril John Roby Hoffmeister, Ca [illegible] Middlesex Hospital; Gerald Holroyde, [illegible] le Veil King and James Johnston [illegible] Harold Howard Leeson, St. George [illegible] Middlesex Hospital; John Falconer McQueen, Ki [illegible] Beare Martin, Owens College, [illegible] Milburn, [illegible] Matthews, London Hospital; Oscar Le Fevre [illegible] St Mary's Hospital; College Hospital; William Alexander Owen, University of Birmingham and London George Downing Perry, Stanley Arthur Piper, and Hospital; George Ramsey Phillips, Horace John D'Arcy John Lawson Rankine, Guy's Hospital; Birmingham Gerrard Price and Thomas Reginald St. Johnston, Manchester; University; Felix Rawsthorne, Owens College, Norman Vaughan Hurry Riches, University College, Cardiff; [illegible] Reginald [illegible] Skinner, [illegible] Hospital; [illegible] tratford, [illegible] Bartholo- [illegible] eckshaw [illegible] St. Bar- [illegible] James [illegible] Guy's Hospital.

Anatomy only.—Mr. John William Heekes, Charing Cross Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Members of the Royal College of Surgeons and have received their diplomas:—

[illegible] University and [illegible] College [illegible] erbert [illegible] St. [illegible] Vigors [illegible] B.A. [illegible] James [illegible] St. [illegible] ersity [illegible] dlesex [illegible] Cardiff, [illegible] pbell, [illegible] M.D. [illegible] orman Clifton Carver, Cambridge University and St. Thomas's Hospital; James Hornidge Chauncey and Arthur Allen Foster Clarke, St. Thomas's Hospital; George Russel Haines Chell, Birmingham University; John Wheeler Cleveland, St. Bartholomew's Hospital; George Martin Clowes, London Hospital; Percival [illegible] Claude [illegible] Walter [illegible] King's [illegible] Westminster Hospital; Stanley Trefusis Crump, Yorkshire College and General Infirmary, Leeds; Alan Davidson, M.D McGill, McGill College, Montreal, and University College Hospital; George Brocklesby Davis, M.A. Camb., Cambridge University and London Hospital; John James Davis, M.D West. [illegible] St. Bartholomew's Hos- [illegible] Lond., and John Jones, [illegible] Desmond King, Middlesex [illegible] B A. Camb., Percy Arnold [illegible] yal Infirmary, Liverpool; [illegible] University and St. Mary's [illegible] Ceylon, Ceylon Medical [illegible]

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—R. H. Cooper (Section I.), Charing Cross Hospital; and [illegible] I.), Guy's Hospital; R. H. [illegible] Hospital; W. G. Kinton [illegible] berts (Section II.), Cam- [illegible] S. Zweilack (Section II.), [illegible] Guy's Hospital. [illegible] and St. George's Hospital; and [illegible] anted to the following candidate, [illegible] surgery, and midwifery:—W. G. Kinton.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidate having passed the necessary examination has been admitted a Fellow of the College:—

A. T. Mulhall, L.R C P. & S. Irel.

The following candidates have passed the primary part of the examination:—

T. A. Burke, S. C. Clarke, J. F. Devane, M. D. Healy, J. J. Hogan, J. Prendiville, and J. R. Tobin.

The following candidates having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College:—

C. de Foubert and H. D. Griffith.

The following candidate has passed the primary part of the examination:—

W. Matthew.

UNIVERSITY OF OXFORD.—The Board of Faculty of Medicine has issued a regulation that the *vivâ-voce* examination in the examination in pathology for the B.M. degree shall no longer take place during the practical examination but shall be held as a separate part of the examination. By a statute just passed the University has instituted changes of importance in the final examination for the B.M., B.Ch. degrees. Hitherto, the examination in forensic medicine and public health has been conducted by the examiners in medicine, surgery, and midwifery, but in future there are to be two specially appointed examiners for these subjects and the examination will consist of a three hours' paper and a *vivâ-voce* examination. This examination has also been placed on the same footing as that in pathology, in that a candidate may take it at any time after he has passed the first B M. examination. It has been enacted, further, that a time-table of the days and hours of examinations for the B.M. degree shall be prepared by the Board of Faculty of Medicine in each Easter term for the ensuing academic year and that each examination shall begin on the Thursday of the eighth week of full term (Michaelmas or Easter as the case may be). The medical examinations have also been subject to the same supervision as the other public examinations of the University in that the conduct of the examiners in regard to the examinations is now brought under the control of the Vice Chancellor and proctors. —On the question of exemption from Greek, by very narrow majorities in a largely attended house, Congregation has recently passed resolutions to the following effect: "That members of the University should not be required to have satisfied the masters of the schools in Greek before presenting themselves as candidates in the honour schools of natural science and mathematics provided that they have satisfied the masters of the schools in the matter allowed as a substitute for Greek. That the matter allowed as a substitute grants, I understand, amounted to £4788. No grants have since been made from county sources for building purposes. A further sum of £17,393 has been expended on new buildings since the date of the report, all of which was privately provided.

A Vaccination Case.

Mr. CORRIE GRANT asked the Secretary of State for the Home Department whether he was aware that Mr. Pratt, of Balderton, applied three times to the Newark county petty sessions for an exemption certificate from vaccination for his child and was refused and that on the first two occasions his application was rejected because he had not a medical certificate that his child was unfit for vaccination; and whether in view of the misapprehension among many magistrates as to their duties in this matter he would propose amending legislation, substituting a statutory declaration of conscientious objection for the present application to the magistrates.—Mr. AKERS-DOUGLAS replied: I have been made aware of this case by a letter from Mr. Pratt. The question of amending the Vaccination Acts does not fall within my department.

MONDAY, FEB. 22ND.

Mishap at Portsmouth Lunatic Asylum.

Mr. REMNANT asked the President of the Local Government Board whether his attention had been directed to the recent deaths by poisoning of four inmates of the Portsmouth Lunatic Asylum and to the evidence given at the inquiry by the coroner disclosing want of care in the dispensing arrangements in that public institution; and whether, in view of the danger to life involved in leaving the important duty of compounding medicines to unqualified persons steps would be taken by the department to insure that every dispensary under the control of a local authority shall be in the charge of a person holding the qualification under the Pharmacy Acts.—Mr. AKERS-DOUGLAS answered: The inquest in this case is not yet concluded, but my honourable friend may be assured that the point to which he draws attention will be carefully considered.

Overcrowding of Union Schools.

Sir ERNEST FLOWER asked the President of the Local Government Board whether he was aware that the certificate of the union schools of the West Ham guardians, which in November, 1901, was exceeded by 169 children and in November, 1902, and September, 1903, was still exceeded, is at present exceeded by over 200 children; that the boys are entirely without day-room accommodation; that 144 girls have day-room accommodation of 23 feet 6 inches by 18 feet 2 inches only; that 86 infants have a day room in which they also take their meals of 27 feet 2 inches by 18 feet 2 inches only; and whether, seeing that this overcrowding makes it impossible to isolate infectious diseases and that skin and eye complaints are present in the same dormitory, he would urge on the guardians the necessity of ascertaining if all those children at present dependent on the rates are entitled to such maintenance and of providing temporary accommodation by hiring houses in which small groups of children might be placed.—Mr. LONG replied: I am aware of the overcrowding at these schools and have impressed upon the guardians the serious responsibility which attaches to them in this matter. The guardians inform me that they are endeavouring to make arrangements for boarding out some of the children beyond the union. I am still in communication with them and I have urged them to hire homes in or near the union or to provide temporary buildings in order to remedy at once the present state of things. I have also suggested that they should have a "call over" of the children with a view of ascertaining if the numbers cannot be reduced.

Experiments on Animals.

Dr. J. G. SHIPMAN asked the Home Secretary whether his attention had been called to the statement made by Mr. Bayliss, in his evidence in Bayliss *v.* Coleridge, that the inspector appointed under the Cruelty to Animals Act, 1876, visited University College on an average once a week during the period Mr. Bayliss was conducting his researches and lectures there; whether he would state the exact number of visits paid by the inspector to University College during the year 1902; whether the inspector was officially connected with University College; and how many times the inspector visited each of the other places registered for vivisection in 1902.—Mr. AKERS-DOUGLAS replied as follows: 12 visits to University College in 1902 were reported by the inspector, but I understand that owing to his constant attendance at the College he was able to pay many visits to the laboratory, and these, when he found nothing special to report, were not included in his return. The inspector is professor of anatomy in University College, London. During 1902 the inspector and the assistant inspector paid 106 visits to the other registered places in England and Scotland, making an average of just under two visits to each place.

Dr. SHIPMAN asked the Home Secretary whether, in view of the fact that the inspector appointed under the Cruelty to Animals Act, 1876, only witnessed the whole of one and part of 11 experiments out of the total of 14,906 performed in 1902, he would consider the advisability of increasing the number of inspectors.—Mr. AKERS-DOUGLAS said: It has to be remembered that, of the 14,906 experiments mentioned in the question, 12,776 were of the character of inoculations or feeding experiments. Further, apart from the actual experiments witnessed, large numbers of the animals have been seen by the inspectors and their condition after the initial experiment has been examined. I am satisfied that the inspection is sufficient to keep me fully informed as to the practical working of the Act and the observance of its provisions, but if at any time I come to the conclusion that more inspection is desirable I shall not hesitate to endeavour to obtain the necessary increase of staff.

No Legal Standard for Whisky.

Mr. KILBRIDE asked the Chancellor of the Exchequer whether he would appoint a committee of analytical experts to fix a legal standard in the case of whisky, such as is done in other articles of consumption, in order to protect the public against spurious substitutions.—The CHANCELLOR OF THE EXCHEQUER replied: The Board of Inland Revenue does not think that it would be of any practical use to attempt to fix a legal standard for whisky. There is already a legal standard of strength below which whisky may not be sold without notice and other conditions must necessarily vary according to the taste of the consumer.

Notes, Short Comments, and Answers to Correspondents.

THE ACTION OF SELENIUM, TELLURIUM, AND ARSENIC ON MUSCULAR TISSUE.

THE February number of the *Medical Chronicle* contains a short account of some physiological experiments with selenium, tellurium, and arsenic made by Dr. H. J. Crompton, resident medical officer in the Royal Infirmary, Manchester. He commences with a reference to the increased attention recently given to selenium owing to the suggestion made by Dr. F. W. Tunnicliffe and Mr. Otto Rosenheim that this substance was associated with arsenic in the cases of beer poisoning which occurred in the North of England in 1900 (THE LANCET, Feb. 2nd, p. 318, Feb. 9th, p. 434, and March 30th, p. 927, 1901). In view of this statement Dr. Crompton investigated the action of selenium compounds on the nervo-muscular tissues of the frog by experiments (1) on voluntary muscle and motor nerve trunks, (2) on the involuntary muscles contained in the walls of the blood-vessels, and (3) on the cardiac muscle. At a later date he made similar experiments with compounds of tellurium and arsenic. For the experiments on voluntary muscle the gastrocnemius of a frog was removed from the animal, supported at its ends on brass wires, and immersed in a 0·75 per cent. solution of sodium chloride ("normal saline"), containing also a known proportion of selenate, selenite, tellurate, arsenate, or arsenite of sodium. Electrical currents were passed at intervals and the shortening of the muscle thereby produced was recorded on a revolving drum. Experiments on the heart muscle were made by means of the tonometer described by Roy, in which an isolated frog's heart tied to a cannula through which the solution under investigation can be perfused is placed in a small air-tight vessel filled with olive oil; variations in the volume of the ventricle are indicated by the rising and falling of a piston. The general results of the experiments were to the effect that although the above-mentioned salts are destructive to animal life, solutions of them nevertheless have no directly poisonous effect on either the voluntary muscle, the motor nerve trunks, or the cardiac muscle of the frog.

QUACKERY AND CREDULITY.

THE following advertisement appeared in the *Birmingham Daily Mail* of Feb. 13th:—

> ADVERTISER would sell Cancer, Tumour, and Polypus Cure, price One Thousand Guineas, or would Cure. Personal Testimonials —M. Vernon, 49, Church Vale (Square), Handsworth. At Home, Mondays, 12 till 4.

We cannot congratulate our contemporary upon the insertion of such an advertisement as the above. We have no doubt that M. Vernon will sell, but what he sells will not be a cancer cure but his dupes, of whom there will probably be not a few.

PAYMENT OF MEDICAL WITNESSES.

To the Editors of THE LANCET.

SIRS,—To those who lightly set out to tender evidence in a magistrate's court may I indite a warning. The fee that you will get for a twelve-mile drive and a ruined morning's work is not that which many would have you believe—namely, one guinea and mileage - but depends entirely upon your power of awakening the sympathy of the bench for your sufferings. They have the power to award you anything from a modest ½*d*. up to the stately two guineas. How best to avoid the half-guinea appearance and to assume the guinea deportment I fain would learn. Anyway, a kind word to a magistrate whenever you meet one may, when the subpœna cloud hangs over you, meet with its reward even in this life.

I am, Sirs, yours faithfully,

Castle Cary, Somerset, Feb. 20th, 1904. DAVID PRICE, M B. Lond.

AN OBSERVATION ON THE VALUE OF GARLIC AS A REMEDY.

To the Editors of THE LANCET.

SIRS,—I have read with interest the article by Dr. Giulio Cavazzani and the letter from Dr. W. C. Minchin upon the use of garlic in tuberculosis and I should like to record that it is not only in this disease that it is of service. I have used it with success in bronchial conditions, notably in bronchitis of the finer tubes where the patient complains that his chest "feels stuffed up" and where on auscultation there is heard a large number of sibilant râles. Also in cases where there is much purulent expectoration. In these cases, after the exhibition of the drug, there has been much relief. The active principle, sulphide of allyl, is undoubtedly excreted into the respiratory passages and may very possibly act as an antiseptic. I note that Dr. W. Ewart in Allbutt's "System of Medicine," quoting Dr. G V. Poore's work on Nervous Affections of the Hand and Other Studies, recommends it in the treatment of bronchiectasis. I have given 15-grain doses of the bulb chopped up and administered in cachets three or four times a day.

I am, Sirs, yours faithfully,

Retford, Feb. 19th, 1904. HANWAY R. BEALE, M D. Lond.

THE MICROSCOPE IN INDIAN PRACTICE.

ARTICLES and letters under the above heading have been appearing in recent numbers of our contemporary, the *Pioneer*. The writer of one letter, a medical man, though it is not apparent whether he is a civilian practitioner or a member of the Indian Medical Service, brings a rather strong indictment against some of his professional brethren whom he accuses of being too lazy or incapable to examine the blood of every patient suffering from "fever," even when they have a microscope. The supply of microscopes is doubtless rather limited, but possibly the varieties of climate to be met with in India may be responsible in some measure for this. A one-twelfth inch objective would be difficult to keep in order during the monsoon on the Kanara coast and we fancy that most of the Indian medical men who have the capacity and training to use a microscope for the diagnosis of the malarial parasite do so, the microscope being supplied by themselves.

◆

F R C.S (Eng) has asked us questions to which it is very difficult to give definite answers in the absence of complete local knowledge. We will communicate with him.

Clock will find an extended memoir of Sir Andrew Clark in THE LANCET of Nov. 11th, 1893, p. 1222. The late physician was well known to us.

Interested has omitted to send his name.

FRIDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.)

SATURDAY (5th).—Royal Free (9 A.M.), London (2 P.M.) Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.0 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (29th).—Medical Society of London (11, Chandos-street, Cavendish square W.).—9 P.M. Mr. C. B Lockwood: Aseptic Surgery in Theory and Practice. Lecture III. Environment and Results. (Lettsomian Lecture.)

WE [illegible] x (20, Hanover- [illegible] egnant Fibroid [illegible] Walker (intro [illegible] roscopical and Lantern slides showing Mitotic Changes in Cancer Cells Papers:—Mr. H. Cripps and Dr. H Williamson: Two Cases involving the Question of the Site of Impregnation —Mrs. Boyd: Two Cases of Abdominal Hysterectomy for Fibroids complicated by Pregnancy, with Specimens.

THURSDAY (3rd).—Röntgen Society (20, Hanover-square, W.)—8.30 P.M. Presidential Address:—Some Laboratory Notes of the last Six Months.

Childhood Society (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Lecture:—Prof. W A. Potts: The Protection of Feeble minded Children during and after School Age.

British Balneological and Climatological Society (20, Hanover-square, W.).—5.30 P.M. Discussion on Obesity (opened by Dr. L. Williams).

FRIDAY (4th).—Society of Anæsthetists (20, Hanover-square, W.).—8 30 P.M. Paper:—Dr. D. Buxton Communications by the President (Mr. C. C. Braine) and Dr. Flux. Annual General Meeting.

Laryngological Society of London (20, Hanover-square, W.).—5 P.M. Cases, Specimens, &c., will be shown by Dr. McBride, Dr. F. Potter, Dr. Smurthwaite, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (29th).—Royal College of Surgeons of England.—5 P.M. Prof. L B. Rawling: Fractures of the Skull, including Mechanism, Pathology, Complications immediate and remote, and Treatment. (Hunterian Lecture)

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Practical Surgery.

[illegible] LINIC (22, Chenies-street, [illegible] (Skin.) 5.15 P.M. Dr. [illegible] the Common Forms of [illegible]

University of London.—5 P.M. Lecture:—Dr. A. E Wright: Physiology of Immunisation.—On Anti-tubercle Inoculation.

TUESDAY (1st).—Royal College of Physicians of London (Pall Mall East)—5 P.M. Dr. W. Williams: Deaths in Childbed, a Preventable Mortality. (Milroy Lecture.)

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. C. Williams: High Frequency Currents (illustrated by lantern slides).

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M. Dr. C. Thompson: Clinique. (Medical.) 5.15 P.M. Dr. D. Grant: Some Common Errors in the Diagnosis and Treatment of Diseases of the Throat.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury).—3 30 P.M. Dr. Tooth: Cranial Nerves.

[illegible] Treatment. (Hunterian Lecture)

Post Graduate College (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard: Practical Medicine.

Medical Graduates' College and Polyclinic (22, Chenies-street, W C.).—4 P.M. Mr. A H. Tubby: Clinique. (Surgical.) 5.15 P.M. Dr. F. J. Smith: Cough and its Significance.

Hospital for Consumption and Diseases of the Chest (Brompton).—4 P.M. Dr. P. Kidd: Types of Pulmonary Tuberculosis.

London Temperance Hospital (Hampstead-road, N.W.)—4 P.M. Lecture:—Diseases of the Stomach. (Post Graduate Course)

THURSDAY (3rd).—Royal College of Physicians of London (Pall Mall East).—5 P.M. Dr. W. Williams: Deaths in Childbed, a Preventable Mortality. (Milroy Lecture.)

Post-Graduate College (West London Hospital, Hammersmith-road, W.)—5 P.M. Mr. S. Edwards: Gleet and its Treatment.

Medical Graduates' College and Polyclinic (22, Chenies-street, W C.).—4 P.M. Mr. Hutchinson: Clinique (Surgical.) 5.15 P.M. Dr. F J. Smith: Cough and its Significance.

Samaritan Free Hospital for Women (Marylebone-road, N.W.).—3 P.M. Dr. F. J. McCann: The Treatment of "Irritable Bladder" in Women.

Charing Cross Hospital.—4 P.M. Dr. Bosanquet: Demonstration [illegible] urse.)

[illegible] PTION AND DISEASES OF THE [illegible] P.M. Dr. F. Price: Mitral [illegible] Graduate Course)

[illegible] THE SKIN (Leicester square. [illegible] ycosis (Chesterfield Lecture)

The Hospital for Sick Children (Gt. Ormond-street, W.C)—4 P.M. Mr. Collier: The Surgical Anatomy of the Ear in Children.

Royal Institution of Great Britain (Albemarle street, W.)—5 P.M. Prof. H. L. Callendar: Electrical Methods of Measuring Temperature.

FRIDAY (4th).—Royal College of Surgeons of England.—5 P.M. Prof. L. B. Rawling: Fractures of the Skull including Mechanism, Pathology, Complications immediate and remote, and Treatment. (Hunterian Lecture)

Post Graduate College (West London Hospital, Hammersmith-road, W.)—5 P.M. Dr. Saunders: Rickets and its Treatment.

Medical Graduates' C [illegible] street, W.C.).—4 P.M. Mr E [illegible]

National Hospital fo [illegible] Queen-square, Bloomsbury).— [illegible]

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

For the United Kingdom.				To the Colonies and Abroad.			
One Year	£1	12	6	One Year	£1	14	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westmin [illegible]) should be made payable [illegible] THE LANCET Offices, 42 [illegible]

During the week marked copies of the following newspapers have been received *Western News (Galway), Westmeath Independent, Southampton Times, Aberdeen Free Press, Aberdeen Free Press (Weekly), Westminster Gazette Windsor and Eton Express, South Wales Daily News, Walsall Advertiser, Surrey Advertiser, Reading Mercury, Mining Journal, Local Government Chronicle, Yorkshire Herald, Daily News Daily Chronicle, Standard, Liverpool Post, Westminster Hospital Gazette, &c.*

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Astier, Asnières; Dr. Francis J. Allan, Lond.; Dr. Donald Armour, Lond.

B.—Mr. J. W. Benson, Lond.; Mr. F. E. Bissell, Kingstone; Mr. T. Bell, Lancaster; Mr. E. Baker, Birmingham; Messrs. Brady and Martin, Newcastle-on-Tyne; Messrs. Burroughs, Wellcome, and Co., Lond.; Dr. F. C. Bury, Riverhead; Buntingford House, Buntingford, Medical Superintendent of; Messrs. Burgoyne, Burbidges, and Co., Lond.; Mr. E. H Blake, Lond.; Mr. A. H. Bostock, Chichester; Mr. Bradburne, Ryde; Dr. Geoffrey Bate, Brighton; Dr. H. C. Bastian, Lond.; Mr. C. L Bedford, Lond.; Dr. D. H. Beegling, Huddersfield; Mr. A. Bird, Sidmouth; Dr. Byrom Bramwell, Edinburgh; British Medical Benevolent Fund, Hon. Secretary of; Dr. D. Bower, Bedford.

C.—Mr. R. B. Canning, Lond.; Mr. J. Cantlie, Lond.; Mr. W. Watson Cheyne, Lond.; Messrs. Samson Clark and Co., Lond.; Messrs. Crossley and Co., Lond.; Messrs. Cole and Co., Lond.; Messrs. Carnrick and Co., Lond.; Messrs. J. W. Cooke and Co., Lond.; Cambridge Scientific Instrument Co., Manager of; Chesterfield Hospital, Secretary of; Clayton Hospital, Wakefield, Secretary of; Mr. Digby Cotes-Preedy, South Croydon; Dr. J. Cropper, Chepstow; Dr. Myer Coplans, Lond.; Cancer Hospital, Lond., Secretary of; Childhood Society, Secretary of.

D.—Dr. F. Dittmar, Scarborough; Mr. F. Davidson, Lond.; Dr. T. Donnelly, Dublin; Dr. A. Darier, Paris; Mr. T. Dixon, Lond.; Mr. Robert Debenham, Lond.

E.—Messrs. Elliott, Son, and Boyton, Lond.; Professor T. Crisp English, Lond.; E. W. P. B; Dr. J. Eyre, Lond.

F.—Mr. F. Friedlaender, Berlin; Mr. A. W. Fyfe, Starcross; Dr. F. W. Forbes-Ross, Lond.

G.—Messrs Gale and Co., Lond.; Messrs. R. C. Gooptu and Sons, Calcutta; Dr. T. Guyot, Paris; Dr. A. Stanley Green, Lincoln; Mr. E. Ganse, Cardiff; Messrs. J. Gabriel and Co., Manchester; Messrs. W. and A. Gilbey, Lond.; Dr. James Gilroy, Waterbeck; Mr. J. S. Gaskell, Beckenham; Mr. A. Graham, Southampton.

H.—Mr. P. H. Hammersley, Lond.; Mr. A. Hind, Birmingham; Dr. John Haddon, Hawick, N.B; Hibernicus, Birkenhead.

I.—International Plasmon, Lond.; Iron-Ox Remedy Co., Lond.

J.—Dr. Arthur James, Lond.; Jeyes' Sanitary Compounds Co., Lond.; Messrs. Jewsbury and Brown, Manchester; J. C. R.; Mr. J. Fred Jennings, Lond.

K.—Mr. S. Karger, Berlin; Messrs. R. A. Knight and Co., Lond; Messrs. G. Kelly and Co., Lond.; Mr. S. J. J. Kirby, Lond.

L.—Leith Hospital, Secretary of; Captain G. Lamb, I.M.S., Kasauli, Punjab; Mr. Charles Ling, Keighley; Mr. C. B. Lockwood, Lond.; Legal and General Life Assurance Society, Lond., Secretary of; Dr. R. W. Leftwich, Lond.

M.—Dr. H. C. Mamlock, Paris; Medical Society of Victoria, Melbourne, Treasurer of; Dr. John A. C. Macewen, Glasgow; Dr. W. J. McCardie, Birmingham; Manchester Children's Hospital, Secretary of; Motor Mart, Ltd., Lond.; Messrs. J. Maythorn and Son, Biggleswade; Manchester Royal Infirmary, Secretary of; Manchester Medical Agency, Secretary of; Dr. A. Miller, Warwick; Dr. M. Martin, Glasgow; Medical Graduates' College and Polyclinic, Lond.; Medical Defence Union, Lond., Council of; Mr. A. F. Messiter, Epworth; Mr. U. W. N. Miles, Bewdley; Middlesex Hospital, Secretary-Superintendent of.

N.—Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.; Dr. K. A. Nanavulty, Vankaner, India; Mr. F. D. Nicholson, Lond.

P.—Mr. H. W. Plummer, Asheville, U.S.A.; Protene Co., Lond.; Dr. David Price, Castle Cary; Mr. Y. J. Pentland, Edinburgh; Mr. F. Piggott, Cambridge; Messrs. Peacock and Hadley, Lond.; Plumbers, Worshipful Company of, Lond.

Q.—Queen Charlotte's Lying-in Hospital, Secretary of.

R.—Mr. W. S. Robinson, Moseley; Royal London Ophthalmic Hospital, Secretary of; Royal College of Surgeons, Dublin, Registrar of; Messrs. Reynolds and Branson, Leeds; Professor L B. Rawling, Lond; Rural Housing and Sanitation Association, Lond., Secretary of; Royal Waterloo Hospital for Children and Women, Secretary of.

S.—Dr. J. R. Swanton, Ballydehob; Dr. F. H. Sinclair, Warren Point; Standard Bank of South Africa, Lond., Secretary of; Mr. J. C Smith, Kilpedder; Scholastic, Clerical, &c., Association, Lond.; Messrs. G. Street and Co., Lond.

T.—Captain R. G. Turner, I.M.S., Etawah, India; Mr. J. Lionel Tayler, Lond.; Mr. H. Torrance Thomso, Lond.; Dr. James Taylor, Lond.; Dr. C. Lloyd Tuckey, Lond.

U.—University College, Sheffield, Registrar of.

W.—Surgeon W. A. Whitelegge, R.N., Sheerness; Worthing Borough Association, Secretary of; Professor B. C. A. Windle, Droitwich; Mr. Claude Woakes, Lond.; West London Hospital Post Graduate College, Dean of; Mr J. S. Whitehead, Bradford; Dr. A. Whitfield, Lond.; Dr. F. H. Wiggin, New York; W. G; W. P. K; Messrs. Willows, Francis, Butler, and Thompson, Lond.; Dr. James Weir, Glasgow; Mr. Thomas R. Watson, Nordrach-on-Dee; Dr. T. Jason Wood, Bradford; Messrs. H. Wilson and Son, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Aymard Patent Milk Steriliser Co., Ipswich.

B.—Dr. J. F. Boa, Kildonan; Mr. S. H. Byam, Lond.; Birkenhead Union, Clerk of; Mr. T. Bell, Lancaster; "Brown," Lond.; Mr. G. W. Brown, Hanley.

C.—Mr. G. F. Cotlett, Lond.; Condensed Peptonised Milk Co., Lond.; C. H. P.; Mr. G. W. Collins, Wanstead; Cheltine Foods, Cheltenham, Secretary of; Coachman, Bedford; Messrs. Cassell and Co., Lond.; Mr. E. G. Carter, Chapel-Allerton; Dr. R. Clarke, Lossiemouth.

D.—Messrs. Douglas and Foulis, Edinburgh; Dr. E. A. Doyle, Leigh, Lancs.; Mr. A. Dyett, Sevenoaks; Mr. C. Deck, Bildeston.

E.—Mr. F. K. Etlinger, Stroud; E. E.; Dr. H. L. Evans, Goring.

ABSTRACT OF

The Hunterian Lectures

ON

THE EVOLUTION AND ACTION OF CERTAIN MUSCULAR STRUCTURES OF THE HEART.

Delivered before the Royal College of Surgeons of England on Feb. 22nd, 24th, and 26th, 1904,

By ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, LECTURER ON ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.

LECTURE II.[1]

Delivered on Feb. 24th.

The Movements of the Auricles and Ventricles during Systole.

The manner in which the heart is fixed within the thorax.—The initial difficulty in studying the action of the musculature of the heart is an ignorance of the fixed points or fulcra from which the various parts of the heart act Literature on the heart takes little or no cognisance of such points. A clue to them is afforded by a study of the simple manner in which the heart is fixed in the embryo and in lower vertebrate forms (*Fig. 6*), *for it is out of the* simple condition that the elaborate fixation of the adult heart is evolved. In the embryonic condition the septum transversum (Fig. 6, *s. transv*) which at a later stage forms the central tendon of the diaphragm and basal part of the pericardium, provides a fulcrum for the auricular or venous end of the heart. The auricles are bound to the septum transversum by the venous mesocardium, through which the veins pass to the auricles (Fig 6). The aorta of the simple tubular heart perforates the anterior or cephalic end of the pericardium and is there fixed by the arterial mesocardium. In the adult heart (Fig. 7) these two attachments have become approximated and more extensive but neither in the fœtal nor adult mammalian heart do the ventricles ever obtain an attachment to the pericardial wall, except indirectly through the auricles or aorta. The points at which the great veins or arteries pierce the pericardium serve as fulcra from which the musculature of the heart may act Through the attachment of the cervical fascia to the pericardium the heart is fixed to the upper aperture of the thorax and neck, while below it is attached to the central tendon of the diaphragm by the extensive adhesion of the pericardium to that structure (Fig 7). The diaphragm acts freely on all the fulcra of the heart, as may be seen from Fig. 8 The lungs may be regarded as ligaments which attach the base of the heart to the whole extent of the chest wall. The left auricle is suspended between the roots of the lungs and bound to them by the pulmonary veins and pericardium. The minute that the pleural cavity is opened the lungs collapse and the pulmonary fulcra, on which the base of the heart is poised, are undone. Hence the movements of the heart seen in the opened thorax are not those which take place normally.

Showing the points of fixation of the human heart. a, a, a, Arterial mesocardium. b, b, b, Venous mesocardium.

The production of the negative pressure in the right auricle.—It is admitted by all physiologists that after the systole of the right auricle is over there appears in that cavity a negative pressure which lasts during the opening two thirds of the systole of the ventricles Much of the difficulty which has been found in explaining the suction or negative pressure in the auricle and of its true relation to the ventricle is due to a neglect of the structure and mechanism of the right side of the heart. Burton-Opitz[2] regards the negative pressure in the right auricle as the chief force in filling the heart. He found that over 90 per cent. of the blood that flows during a cardiac cycle in the external jugular vein of the dog passed during the short phase of negative pressure in the right auricle He differs from Dr. Leonard Hill[3] in regarding the auricular negative pressure as [illegible] drawing on the venous blood than that

[illegible] veins of the abdomen The venous hum or bruit heard where the veins of the neck enter the thorax indicates by its loudness the rate of flow of the blood and the degree of negative pressure in the great veins of the thorax. The hum ceases during auricular systole; it is greatest in the opening phase of ventricular systole when the negative pressure appears in the auricle; it is increased

---

[1] Lecture I was published in The Lancet of Feb. 27th, 1904, p. 555.

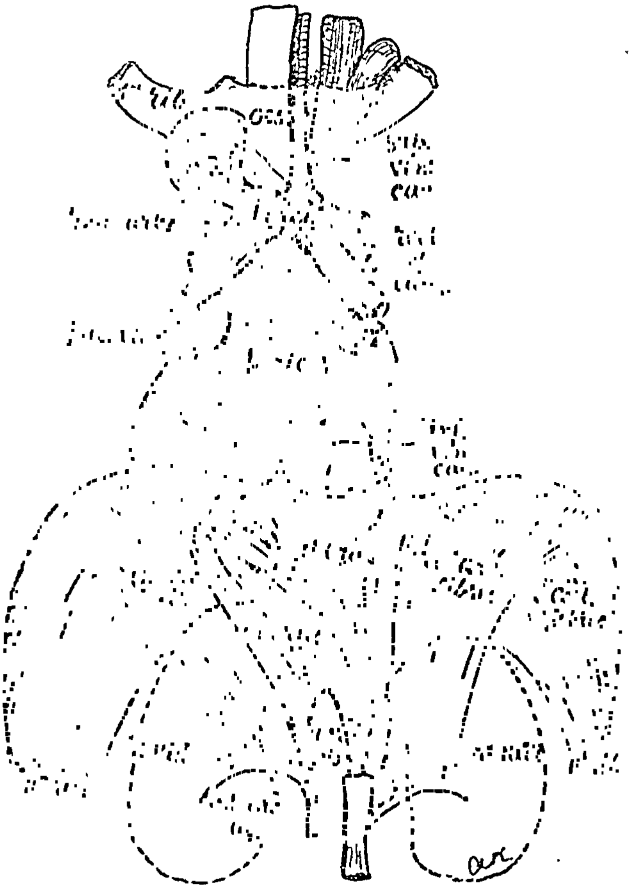
K

during inspiration.[4] John Hunter[5] states that the contraction of the heart by causing a negative pressure in the thorax draws onwards the blood in the veins. Chaveau[6] ascribed the negative pressure in the auricles to the contraction of the ventricle, especially to the pull exerted by the papillary muscles, and Porter[7] accepts a modification of Chaveau's theory. A study of the structure, mechanism, and morphology of the right side of the heart shows that the right auricle is actively expanded by the contraction of the right ventricular wall in all mammalian and avian hearts.

FIG. 8.



The attachments of the diaphragm to the pericardium, heart, and roots of the lungs in the human subject. (From a preparation in which the spinal column has been removed and the parts exposed from behind.) (From THE LANCET of March 7th, 1903, p. 632.)

The constitution of the right auricle.—The right auricle of all vertebrates, and man's is no exception, is made up of two distinct parts, the auricle proper and the auricular canal, each of which plays its own part in systole (Fig. 6). We know from the classical work of Gaskell that the musculature of the auricle proper is more difficult to excite but more rapid in its contraction than that of the auricular canal. The canal represents a primitive part of the cardiac tube on which the auricle proper was developed as a specialised diverticulum. The auricle proper is easily recognised in the human heart by the fact that in it only are the muscle fibres thrown into pectinate bundles. The appendix forms part of the proper auricle. The pectinate bundles arise from the tænia terminalis, which passes, it will be remembered, from the orifice of the superior to that of the inferior vena cava. From that origin they pass on the roof of the auricle to the auriculo-ventricular groove where they turn inwards and fuse with the annular fibres of the auricular canal. That part of the right auricle which forms the auricular canal is sunk within the auriculo-ventricular groove and surrounded by annular fibres; its inner aspect is smo
The inter-auricular septum and the two bands which
across the mouth of the sinus venosus are developed f
and form part of, the auricular canal. Within the sep
the annular fibres of both right and left auricles a
drawing the auricles towards the septum when they cont
The true auriculo-ventricular junction, both in a mor
logical and physiological sense, lies not at the fibrous ring
at the apex of the funnel-shaped tricuspid valve,
auricular canal thus extending to within the cavity of
ventricle. Further, the musculature round the superior
cava and on the coronary sinus is a remnant of that of
sinus venosus, and since it is the most excitable of all
musculature of the heart the auricular systole prob
commences in it.

The manner in which the right auricle contracts.—
wave of auricular contraction, commencing in the mu
lature derived from the sinus venosus, spreads first to
auricular canal, then to the auricle proper. The ann
fibres of the canal act as a sphincter, constricting the ca
and drawing the auriculo-ventricular groove inwards a
backwards, for the only fixed points to which the annu
fibres are attached are the terminations of the superior
inferior cavæ. The pectinate bundles of the auricle pro
draw the base of the right ventricle towards the terminati
of the venæ cavæ, for they arise from the tænia termin
which is attached to, and helps to close, the caval orifi
Thus the pectinate bundles not only force the auricular bl
forwards but also draw the base of the ventricle upwards
to its load. Since the pectinate bundles measure from 35
40 millimetres in diastole and from 15 to 20 millimetres
artificial systole we may infer that the base of the ventri
is drawn upwards to the extent of 15 millimetres or fully h
an inch. That is in harmony with what may be observed
the exposed living mammalian heart.

The diastole of the right auricle and the production of negative pressure.—At the commencement of ventricu
systole the base of the right ventricle moves towards
apex of the heart. That we know from the observations
Haycraft[8] on the heart within the unopened thorax and fr
the records of Roy and Adami[9] and of many others in
exposed heart. The base of the ventricle does not move a
whole; it is rather a hinge movement in which the sept
between the interventricular orifices serves as the axis of
hinge. Now it is to that part of the auriculo-ventricul
canal which is furthest from the septum and undergoes
greatest extent of systolic movement that the pectina
fibres of the auricle are collectively inserted. Hen
as the base of the ventricle swings forwards and for as lo
as it continues to move the pectinate fibres in the roof of
right auricle increase in length and the auricular cavi
increases in dimensions. The elastic tension of the lun
certainly assists in the expansion of the auricle. It
during the period of active expansion by the ventricul
contraction that the venous blood is sucked within
auricle.

Why is it that the base moves towards the apex a
not, as one might expect, the apex to the base? Th
the apex is the part of the ventricles which undergo
the least amount of movement during the natural systo
movement within the unopened thorax is a point on wh
physicians and physiologists are agreed. It is a law whi
runs through the whole vertebrate kingdom, that the apex
rendered an approximately fixed point during ventricul
systole in order that the ventricular contraction may be e
ployed as a means of filling the auricles. The manner
which this effect is obtained in birds and mammals will
shown in a later paragraph to depend on the structure a
manner of action of the left ventricle. Three sets of fibr
take their origin in the apex of the heart and end in t
fibrous tissue of the auriculo-ventricular membranous ri
and by the contraction of which the base is drawn towar
the apex. First, there are the fibres of the superfici
layer which spring from the apical vortex of the le
ventricle and ascend to curve inwards at the base
the right ventricle, terminating on the outer edge of th
membranous ring; secondly, irregular longitudinal band
forming a trabecular meshwork, ascend on the inner aspec
of the lateral wall of the ventricle to end in the membrano
ring at the base; and thirdly, the papillary muscles, whic

also end, through the tricuspid valve, in the membranous ring. All these three sets of muscles act during ventricular systole on the auricle, taking their fixed origin in the apex of the ventricle. Ludwig's statement that the "base apex" diameter of the heart is not shortened in systole of the ventricles has been frequently misunderstood owing to the fact that the base of the heart is made up of two different parts. There is the auricular base of the heart on which the auriculo-ventricular orifices are situated and the arterial base of the heart on which the openings of the aorta and pulmonary artery are placed. The one represents the commencement of the ventricular tube, the other its terminations. Now, if the measurements be taken between the apex and the arterial base during systole it will be found that the distance is but slightly altered, but if the measurements be taken between the apex and the lateral auricular base it will be found that the distance is very materially shortened.

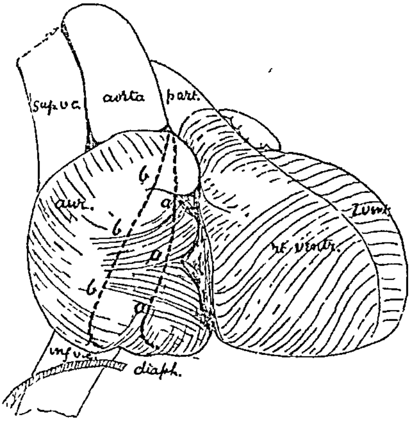
This question remains to be answered: Why is it that the negative pressure within the auricle, if it be due to the contraction of the ventricular wall, does not last throughout the whole period of ventricular systole? During the latter third of that period the pressure rises rapidly in the auricle and the flow of the blood in the great veins is arrested and they swell, giving then an upstroke if a tracing be taken of the vein. Dr. James Mackenzie has named this rise of pressure in the veins the ventricular wave and regards it as due to the back pressure following on the completed diastolic expansion of the auricle. Were the filling of the auricles due to a force which acted independently of the ventricular systole one would find it difficult to account for the very constant relationship which exists between the systole of the ventricle and the auricular negative pressure. The right auricle is attached to only one part of the right ventricle, that part into which the auriculo-ventricular orifice opens, which is rough-walled and contains the papillary muscles. The infundibular part which lies above the level of the auriculo-ventricular opening in the upright position of the body is smooth-walled and its contraction could not affect the auricle in any way. From embryological evidence one would expect the papillary compartment of the ventricle, which is the most capacious, to contract before the infundibular, for the embryonic peristaltic cardiac waves pass from the auricular to the aortic orifice of the ventricles. The triphasic wave of negative variation which Starling and Bayliss observed during systole of the mammalian ventricle can only be understood if one grants that the wave of contraction passes from auricular base to apex and from apex to arterial base of the heart.

Three other phenomena which occur during ventricular systole have to be accounted for. Mackenzie's[10] tracings show that the liver is elevated and the region of the thorax in contact with the right ventricle is drawn inwards during the period in which negative pressure appears in the auricle—that is, during the period in which the papillary compartment of the ventricle is in a condition of active contraction. On the other hand, the inspiratory (cardio-pneumatic) movement[11] caused by the systole of the ventricle reaches its maximum during the latter third of ventricular systole when the infundibular part, which lies in contact with the lungs and cannot draw the auricle into the space it vacates, is in an active state of contraction. In short, the negative pressure set up by the contracting ventricle is expended during the opening two-thirds of systole, when the papillary compartment is in active contraction, in drawing blood into the auricles and in the later third, when the infundibular part is emptying, in drawing air into the lungs.

The second phase of negative auricular pressure.—When ventricular systole is over and the tricuspid valves again open a second and slight phase of negative pressure appears in the auricle and great veins. Burton-Opitz found that it had a very slight effect on the flow of blood in the veins. One would expect that the throwing open of the great ventricular chamber, especially if the negative pressure which occurs in it at the end of systole acted effectively on the venous flow, that there would be marked fall of pressure in the auricle and a rapid flow in the veins. None of these are present because at the end of ventricular systole the base of the ventricle returns to its diastolic position, encroaching on and emptying the auricle. The return of the ventricular base is probably assisted by the elastic tissue which is well developed in the auricular wall.

The effects of distension on the movements of the right auricle.—In Fig. 9 is represented a heart in which the right auricle is greatly distended as a result of mitral and tricuspid stenosis. It will be observed that the lateral part of the base of the right ventricle, even in the diastolic position, is pushed towards the apex of the heart by the greatly distended auricle—that is to say, that it occupies a position in diastole which could not be reached even in the most profound contraction that the right ventricle could make in the natural heart. Hence, in such a heart there can be no forward movement of the ventricular base during systole and no traction on, and dilatation of, the auricle. As the auricle becomes more and more dilated the first negative phase, as indicated in tracings of the pulsation of the jugular vein, becomes less, while the second phase, which occurs when the mitral valves are opened, becomes greater and greater till at last, as shown in Mackenzie's tracings, the second or ventricular wave has completely absorbed the auricular wave. In short, when the walls of the auricle become permanently distended, the contraction of the ventricle can no longer exert its force in drawing onwards the venous blood, because the means whereby it produced the negative pressure in the auricle no longer exist. If Burton-Opitz is right in regarding the negative pressure in the auricle as the chief means of drawing onwards the venous blood when the body is in a state of rest, then one can understand the grave effects which follow the annihilation of this force by the permanent dilatation of the auricle.

FIG. 9



Heart (viewed from the right and in front) in which there was mitral and tricuspid stenosis with great distension of the right auricle and elongation of the auricular canal. Jugular pulsation of the ventricular type was present before death (from one of Dr. Mackenzie's specimens). *a*, *a*, *a*, The normal position of the auriculo-ventricular groove in diastole. *b*, *b*, *b*, Its normal position at the beginning of ventricular systole.

The effect of distension of the auricles on the position of the [illegible] to the left, [illegible] materially alter its position, it is not realised that the alteration is mostly due to the distension, not of the ventricular but of the auricular chambers. The right auricle is fixed to the terminations of the venæ cavæ and to the pericardium between them. It is wedged into the right posterior angle of the heart between the base of the right ventricle in front and the left auricle behind (see Figs. 10 and 11). If it becomes distended it pushes the base of the right ventricle forwards and turns the apex of the heart to the left whether the right ventricle be hypertrophied or not. The left auricle, on the other hand, is suspended between the roots of the lungs and occupies a central position on the posterior part of the cardiac base. If it becomes dilated it pushes the whole heart forwards. When atrophy of the heart is present (Fig. 11), so that there is ample room in the chest to allow the movement to take place, the apex of the heart turns somewhat to the right (Fig. 11) but if there is hypertrophy, the heart exceeding in its base-apex diameter the corresponding measurement of the chest, then this movement is prevented by the apex coming in contact with the chest wall (Fig 10).

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. Tangl has been promoted to the Ordinary Professorship of Physiological Chemistry.—*Iurieff (Dorpat):* Dr. Yarotski has been appointed Extraordinary Professor of Internal Medicine.—*Paris:* Dr. Berger has been transferred from the chair of Operations to that of Clinical Surgery in succession to Dr. Duplay who is retiring.—*Vienna:* Dr Siegmund v. Schumacher has been recognised as *privat-docent* of Anatomy.

ABSTRACT OF

The Hunterian Lectures

ON

THE AFTER-EFFECTS OF HEAD INJURIES.

Delivered at the Royal College of Surgeons of England on Feb. 15th, 17th, and 19th, 1904,

BY T. CRISP ENGLISH, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

LECTURE III.[1]

Delivered on Feb. 19th.

MR. PRESIDENT AND GENTLEMEN,—In the following lecture I shall first speak of that form of traumatic cerebral abscess in which the onset of symptoms is preceded by a period of latency; I shall then refer briefly to traumatic epilepsy; and lastly I shall discuss the surgical aspect of traumatic insanity.

LATE TRAUMATIC CEREBRAL ABSCESS.

In the 400 consecutive cases of fracture of the skull upon which my Jacksonian essay was based were three instances of cerebral abscess. In two of these symptoms were latent, in one for a period of ten years, in the other for a much shorter period—namely, four weeks.

The following are the details of the first case. The patient was a woman, aged 31 years. Ten years before admission into hospital she was injured in a boiler explosion. An operation was performed shortly after the accident and she ultimately returned to her work apparently cured. She remained in excellent health and free from all cerebral symptoms until eight years after the accident, when an attack of acute pain in the left side of the head with great tenderness at the site of the injury occurred. There were tingling down the right arm and vomiting, no paralysis, and no rise of temperature. The attack passed off in three or four days and beyond occasional headaches no further symptoms were noticed until one month before admission; very severe headache now started with frequent vomiting; movements and sensation were apparently perfect and no other disturbances were noted. Such was the history given by the medical man who sent her to hospital. When examined in January, 1901, ten years after the accident, the patient was looking extremely ill and complained of intense pain in the left temporal region; cerebration was accurate but very slow. The left side of the face was marked with bluish scars, the result of the gunpowder explosion. Two inches above and one and a half inches behind the external auditory meatus was a surgical scar, under which the bone was extremely irregular and depressed; the scar was excessively tender. No paralysis was detected. Bilateral optic neuritis was found, being most intense on the left side. The pupils were normal; the deep reflexes were exaggerated; the pulse was 64, regular and full; and the temperature was 98° F. Examination of the ears showed nothing abnormal and hearing was good. A cerebral abscess was diagnosed and operation was performed two days later. The bone was found depressed and presented tattoo marks from the old injury. An abscess in the temporo-sphenoidal lobe was readily found and about one ounce of thin green odourless pus was let out. A silver drainage tube was introduced. A fortnight later she was doing excellently; there had been no return of the headache or vomiting and the optic neuritis was subsiding. Then suddenly symptoms returned and persisted; the brain was again explored on two occasions and a reaccumulation of pus was found, larger drainage tubes being inserted. On the thirty-second day after the primary operation very acute symptoms suddenly supervened, the temperature rose to 104°, and death rapidly occurred. Unfortunately, no necropsy was allowed This case is an excellent example of the latency of a cerebral abscess. That it was traumatic in origin there can be no doubt; there was clear evidence of a severe depressed fracture, both ears were healthy, and the abscess was found under the seat of the injury. Until the end of the ten years there had been practically no symptoms suggestive of the condition excepting during the one short attack of headache and vomiting.

---

[1] Lectures I. and II. were published in THE LANCET of Feb. 20th (p. 485) and 27th, 1904 (p. 559), respectively.

The following are the three stages which occur in the clinical history of these chronic abscesses: (1) early slight cerebral disturbance often unnoticed; (2) latent period, which may be complete or incomplete; and (3) terminal stage, usually developing suddenly, sometimes gradually. The period of latency is explained thus: shortly after the primary injury a small abscess forms but the inflammation remains localised if the virulence of the infecting micro-organism is mild. When the acute process stops a membrane is gradually formed round the abscess, shutting it off from the healthy brain tissue, and if this membrane is complete the abscess may be regarded practically as a cerebral cyst; and as long as there are no acute inflammatory changes in the brain or cerebral membranes surrounding it, it may be a very stationary lesion, causing slight or no symptoms; this is especially the case when it is situated in one of the so-called silent areas of the brain. The latent period varies in duration from two or three weeks to several years; the latency is often imperfect and slight symptoms such as headache and slight mental disturbance, usually in the direction of melancholia, are frequently observed.

It is clear that the early diagnosis presents the greatest difficulty owing to the latency of symptoms. Yet suggestive symptoms and signs will often be discovered if the examination be thorough and complete and in such cases routine inspection of the optic discs must be made. In cases of doubt an exploratory operation should at once be performed. If we wait until the symptoms of abscess become unmistakeable the prospects of successful treatment become remote. Fortunately, in the vast majority of traumatic cases the abscess lies a short distance beneath the seat of injury and exploration is easily carried out. I have the notes of ten cases in which a traumatic abscess remained latent for over six months. The following case is perhaps the most striking. At a necropsy on a patient who died in the London Hospital a penholder and nib (three inches long) were found in an abscess at the base of the brain. The abscess was obviously an old one; there were no traces of injury and it was not known how long these articles had been in the brain, but this must have been a great many years; there had been no symptoms until a few weeks before death.

There are certain cases which suggest that the cerebral membranes are more liable to disease after injuries to the head. In one of my cases the patient died from pneumococcal meningitis 11 months after fracture of the base of the skull and in another tuberculous meningitis proved fatal ten months after an extensive fracture of the skull. These cases may be merely examples of coincidence but the association is suggestive. It is interesting in this connexion to refer to the statement of Beger of Leipsic that injuries to the head under the influence of an epidemic of cerebro-spinal meningitis are very apt to be followed by symptoms of meningitis. Brief details of my two cases may be given. In February, 1899, a man, aged 30 years, was admitted into St. George's Hospital with symptoms of a fracture of the anterior and middle fossæ of the base. He returned to work three months later, some headache and deafness in the left ear being the only after-effects. In January, 1902, he was readmitted and died with what proved to be pneumococcal meningitis. The other case occurred in the practice of Mr. Francis Jaffrey. A child, aged three years, fell 40 feet on to his head and sustained multiple fractures of the vertex and base of the skull; there was free bleeding from both ears. He recovered in a comparatively short time, but ten months later died from tuberculous meningitis. In all other respects the child had been exceedingly healthy and there was no tuberculosis in the family history.

TRAUMATIC EPILEPSY.

I have previously spoken of the vast amount of literature available on the subject of traumatic epilepsy and I do not intend to add much to it at the present time. The cases which occurred in my series will first be referred to and then I shall speak briefly of certain points in its operative treatment.

Epilepsy occurred in five cases in the first series, in two in the second series, and in 14 in the third or miscellaneous series. There were thus 21 cases in all of epilepsy following head injuries; of these, seven were of the Jacksonian type and in one arachnoid cyst without a fracture was found. The remainder were of the idiopathic or essential type of epilepsy and the preceding injuries had been fractures of the base in six cases and injuries diagnosed as concussion in eight cases. In two-thirds of the cases, therefore, the epilepsy which followed was of the idiopathic variety and for these mental shock, which is well recognised as a potent factor in epilepsy, is largely responsible.

Amongst the cases of Jacksonian epilepsy the following is instructive from the point of view of treatment. The patient, a man, aged 19 years, fell seven feet, striking his head against an iron rail; he was unconscious for 36 hours. He was taken into the Antwerp Hospital and discharged three weeks later without operation. Fits commenced shortly after and he was trephined in New York two months after the injury; the bone was replaced and he left the hospital apparently cured. The fits then returned, and 18 months later he was brought into St. George's Hospital, having been found unconscious by the police. The replaced crown of bone was felt over the left Rolandic area as a considerably depressed circle. Further operative treatment was advised but refused. In criticising this case, it is clear that operation should have been performed in the first place —a line of treatment without any possible exception in punctured fractures over the Rolandic area. It is also clear that the crown of bone removed when operation was performed later should not have been replaced, for it was now felt as a depressed circle and the fits were continuing. An arachnoid cyst was discovered in a boy, aged 15 years, who had fallen 40 feet from the rigging of a ship on to the deck and who had later developed focal epilepsy. There were slight paresis of the right leg and a small tender scar over the upper part of the left Rolandic area. Trephining was performed at this spot and an arachnoid cyst containing about two ounces of serous fluid was opened. I am unable to say how long a period of relief followed the operation, for the boy was lost sight of six months later.

The history of the operative treatment of traumatic epilepsy is one long tale of disappointment and we are driven to the conclusion that we cannot cure this disease. The earlier statistics which gave so much hope have been long known to be useless and misleading. There are many fallacies in these figures. It is clear that certain surgeons who published 50 cases or more operated upon in the course of a few years must have included a large proportion of cases totally unsuitable for operation. Further, we know that the word "cure" means nothing but a temporary cessation of the fits, for it is the universal experience that convulsions almost invariably recur sooner or later. In a few exceptional cases a long period of relief follows, as in Sir Victor Horsley's well known case, in which the patient was free for 14 years. In the vast majority the convulsions return within three or more years. Being compelled, then, to admit that at the present permanent cure is out of the question, we must take up an entirely different standpoint. Our best position would seem to be this: if cases are carefully selected and if continued bromide treatment be combined with operation we can reasonably expect to afford the patients relief for a few years. This result will be certainly worth the slight risk incurred in the operation. Freedom from fits for two years or more will mean much to the patient and we shall further postpone the mental deterioration which inevitably accompanies frequently recurring fits.

The selection of suitable cases is a matter of the greatest importance, for indiscriminate operation will not only result in numerous disappointments but will often aggravate the disease. For those forms of epilepsy which conform to the idiopathic type nothing, of course, can be expected from surgery. The cases which are suitable for operation are those in which there is evidence of a definite injury, in which the epilepsy is Jacksonian with localised convulsions, in which the disease has not lasted for more than two years, and in which there is no neurotic family history. When the convulsions are generalised the prospects of success are slight, hence the importance of early operation, for convulsions which are at first local become generalised later. Thus in the case of a scaffolder who fell from the roof of the hospital, the attacks were at first strictly localised to the right side of the face; later the right side of the body was affected, and I found that five years after the injury the convulsions were general and that it was sometimes noticed that they started with twitching of the right side of the face. Although the patient was formerly a

Considerable difference of opinion appears to exist as to the propriety of excision of the cerebral scar and the surrounding unstable portion of the cortex. The majority of surgeons content themselves with the removal of local sources of irritation. Some of the more recent statistics appear to show that the results obtained by cortical excision are better than those in which the superficial structures only have been dealt with, but I have already instanced the dangers of statistics. Each case must be judged on its own merits. We must remember that relief is rarely for long, that the resulting paralysis which the operation causes is not likely to improve much, and that the risks of the operation are considerable. Whatever operation is performed, it is essential that post-operative bromide treatment should be persisted in for years.

The main point, however, in the whole question is this: inefficient surgery is responsible for the great majority of the cases. Fortunately, the incidence of the disease is diminishing with the greater frequency with which primary operations are performed, and when it becomes the routine practice to operate in all cases in which a depressed fracture is suspected traumatic epilepsy will become comparatively rare.

TRAUMATIC INSANITY.

There is reason for believing that mental impairment more frequently follows head injuries than is generally admitted. The only possible way of determining this question is to follow up patients for long periods after the accident, and this I attempted to do, though on a somewhat small scale, in my investigation of the after conditions of the 200 cases of head injury.

In the 100 cases in which there had been a fracture of the skull some degree of mental impairment was observed in 11. One patient, a man, aged 42 years, died in an asylum five years after a fracture of the base; the injury had been severe and when the patient was discharged from hospital obvious mental disturbances were present. Dementia gradually developed, but I have failed to obtain further details of his condition before death. Another patient died four years after fractured base, having suffered from severe epileptic attacks and mental deterioration. Two patients had attempted to commit suicide in melancholic attacks. In two other instances patients who presented marked mental disturbances shortly after their accidents were found to be suffering from dementia subsequently. In one case, one month after a fracture of the base the patient was extremely eccentric in his behaviour, had illusions, was liable to dash suddenly out of bed, and gave a circumstantial account of having done service in the Egyptian and Zulu campaigns, although he had never been abroad. I saw him four years later and found that he presented early dementia, was a chronic alcoholic, and the subject of frequent fits. The other case was that of an old lady who had also sustained a fracture of the base. On the thirty-fifth day after the accident the patient was constantly chattering at everybody passing her bed, was noisy, and could give no rational answer to questions; on the sixtieth day there was much mental improvement but she was still unable to recognise persons or things; on the seventy-fifth day she was discharged, being quiet and fairly sensible, but with much impairment of the intellectual faculties. One year later her mental condition was unimproved.

In the second series there were found one instance of severe mental derangement and three instances in which there was obvious mental deterioration. A boy, aged 18 years, was examined two years after a blow in the right parietal region resulting in concussion; he had been in hospital for 11 days. Mental symptoms had dated from the accident; there was intense depression with frequent attacks of violent and dangerous passion. His memory was extremely impaired; he had delusions and frequently talked wildly and unintelligibly; he shouted and raved in his sleep and had been found sleeping under his mattress. He was previously bright and in excellent health. Nothing was known of his parents.

In my third series of cases, the miscellaneous cases, are four examples of traumatic insanity. The first case was that of a man, aged 38 years, in whom typical and severe melancholia followed slight concussion, the result of a blow in the left parietal region; the patient had previously been confined in an asylum with melancholia, but had been sane for about one year before this accident. The second case was one of mania occurring in a coachman, aged 38 years, ten weeks after a severe cerebral contusion. The condition seemed directly referable to the injury; there had been no previous mental trouble and no apparent predisposition, hereditary or acquired. There has been no recurrence of acute symptoms so far but there is obvious mental derangement. In the third case melancholia followed a shell wound of the head and terminated in suicide. The fourth case was one of dementia seen four years after a fracture of the base in an alcoholic subject. In several other cases there was obvious impairment of the mental faculties but not sufficient to be included under the heading of insanity.

Associated with these cases is that of the boy whom I have brought here to-day. I am showing him not as a case of traumatic insanity, for he is not insane, but as a case which I believe is gradually drifting in that direction. I will briefly repeat his history. Eleven months ago he fell eight feet on to his head and sustained a depressed fracture of the left side of the frontal bone; the primary symptoms were so slight that the parents refused operation for the first 24 hours. He was then operated upon and the depressed fragments were removed; the dura mater was intact. He has been kept under careful observation since. Two months after the accident the child was dull and quiet but somewhat irritable in contrast to his former alertness and cheerfulness; there were frontal headache and giddiness. Four months later there was no improvement; his parents said that he was still dull and strange, that he was more irritable and extremely spiteful to other children and to animals. The child looked sallow and out of sorts, with dark rings under the eyelids; there was still some headache. Last week his father brought him to hospital, being alarmed at his mental condition. The irritability has greatly increased; his parents can no longer manage him. After two or three days' trial he was not allowed to continue attending school owing to his pugnacious habits; he attacked his schoolmaster on the slightest provocation and was continually fighting his school fellows during lesson time. There are other symptoms of mental disturbance; he has lately been attempting to drive knives into his neck and to hang himself with a rope; he appropriates money and other valuables and prefers to take his tea under the table or under a bed. There is no history of nervous trouble in the family and the boy had previously been very intelligent and in excellent health.

There are thus 20 cases in which serious mental disturbance followed injuries to the head; in eight of these the disturbances amounted to actual insanity. A study of the cases as a whole enables one to appreciate certain points in reference to this subject of traumatic insanity.

Comparatively little attention has been paid to the surgical aspect of the condition. The most thorough work on the subject is to be found in an admirable thesis published by H. A. Powell in 1893[2]; to this I shall take the liberty of referring later. Moreover, many operations have been performed for the relief of this condition, but the cases selected have often been unsuitable and the results are frequently disappointing The medical aspect of the question is indefinite and ill-defined, for the difficulties which attend the study of traumatic insanity are very great. There is always a tendency on the part of surgeons and surgical registrars to record carefully the physical symptoms and signs but to pay less attention to the psychical symptoms and the mental condition of the patient. Many patients on discharge from hospital within a few weeks of the accident present symptoms of mental aberration, but no estimate can be formed of the incidence of traumatic insanity from the patient's condition on discharge, for several of these completely recover within a few months. On the other hand, others apparently quite well when leaving hospital develop insanity at some later period. These patients frequently pass through the hands of many practitioners, attend the out-patient departments of one or more hospitals, and finally may drift to the asylums. During this interval between original admission into hospital and the termination in an asylum it is usually extremely difficult to get a connected account of the case.

The relative incidence of trauma to other causes in the production of insanity is variously estimated by different authorities. Thus, Schlager of Vienna states that 10 per cent. of all cases of insanity are traumatic, whilst Clouston found that during nine years at the Royal Edinburgh Asylum less than 1·3 per cent. of the cases of insanity were due to head injuries. Until recent years there has been an evident and widespread aversion to ascribe mental changes to gross lesions and the influence of traumatism has usually been fixed at a minimum by authorities on nervous diseases. Personally I do not think that asylum statistics can give us any accurate idea of the frequency of traumatic insanity. There are undoubtedly a large number of insane persons at large who are never certified as such and this is particularly the case with those who owe their trouble to head injuries, for the duration of the acute attacks is often short and the patients rapidly make an apparent recovery so that removal to an asylum is postponed. In the frequent cases of slight dementia also the symptoms are of a type which do not demand confinement in an asylum, whilst many such patients, and especially the older ones, end their days in the infirmaries and poorhouses.

---

[2] H. A. Powell. The Surgical Aspects of Traumatic Insanity, Oxford, 1893.

The most divergent opinions exist as to the relations between traumatism and insanity and authorities who have studied the question express entirely contradictory views. The matter mainly resolves itself into the answering of two questions: first, can head injuries be the direct cause of insanity? and, secondly, has the insanity which follows head injuries a special symptomatology? In regard to the first question, it will be of interest to refer briefly to the opinions of certain writers. Christien considers that injuries only act by diminishing the resistance of the brain and bringing into play any latent predispositions, and that one sees as a result any one or other of the mental diseases, such as mania, dementia, and general paralysis, not indifferently but depending on the nature and mode of action of other causes. Blanche says that considering the large number of people who do not develop insanity after head injuries it is illogical to consider these as exciting causes but that they should be looked upon as affording heredity and latent predispositions the opportunity of asserting themselves. Tredgold states that in nearly all the cases of insanity due to accidental circumstances, such as difficult labour and conditions occurring after birth, insanity has been present in the ancestors and these injuries can only be considered as contributory factors. Phelps's opinion on this subject is referred to later. He believes that mental disturbances following head injuries are almost invariably due to lesions of the left frontal lobe, but that lesions of the right frontal lobe and other parts of the brain are not followed by insanity. W. W. Keen considers traumatic insanity rare; he says that it sometimes follows accidents more on account of mental shock than of physical brain injury, the cases of true traumatic insanity thus displaying no demonstrable brain lesion. He holds that many of the cases of reported cure are faulty and ridiculous and concludes with the somewhat sweeping statement that the patients either were not insane or still are so. On the other hand, the greater number of authorities hold that insanity may be the direct consequence of head injuries.

To my mind that lesions of the brain may be the actual and direct cause of mental derangement can scarcely be doubted. In certain cases in which there has been gross lesion of the brain or its membranes, and in which insanity has developed immediately or later in connexion with certain symptoms dating from the injury, we are justified in concluding that there is a direct causal relation. This view is strongly supported by the fact that complete and prompt recovery has followed operation in many cases of this nature. As a factor of mental disease, however, injury often acts as a contributory cause. In some cases the operation of this factor is slow, slight, and simply predisposing, or it may lead to the production of a neurasthenia or hysteria on the basis of which may originate a morbid psychosis of traumatic origin. Again the effect of the traumatic factor may be to precipitate a partially prepared or nascent insanity or it may be the direct excitant of an insanity already formed ready to break forth on the stroke. A careful study of a large number of cases brings us to the conclusion that there are two distinct types of traumatic insanity. 1. Direct insanity due to the actual injury to the brain or its membranes and occurring apart from hereditary or other predisposing causes. In four of my eight cases of traumatic insanity the injury appeared to have been the direct cause of the mental symptoms. 2. Indirect insanity—that is to say, any form of insanity occurring as the result of lowered resistance of the brain due to the head injury in patients with a predisposition to insanity, hereditary or otherwise.

Next, there is the question as to whether the insanity which follows head injuries has a special symptomatology. We must clearly differentiate between direct and indirect traumatic insanity. In the indirect form, where the injury is merely a predisposing or contributory cause, it seems clear that it can exert no influence upon the type of insanity which follows. In the direct form, where the injury is the sufficient and exciting cause, the facts are less evident. The larger number of authorities state that there are no characteristic symptoms; some take an intermediate view, suggesting that they were not at all clear in their own minds upon the point. On the other hand, certain authorities state that insanity directly due to traumatism presents special features and that lesions of certain regions will be followed by distinct symptoms.

The etiological importance of injuries to the frontal lobes in the production of mental disease has always been a subject of great dispute both amongst physiologists and surgeons. Every possible variety of opinion has been expressed; for instance, Phelps of New York states that injuries to the left frontal lobe are practically always followed by mental changes and that these changes occur only in injuries of the left frontal lobe. Other surgeons have collected series of cases illustrating the innocuity of injuries to this part of the brain. The results of experiments instituted by physiologists to determine the functions of the frontal lobe have been contradictory or at least variously interpreted. The great majority of physiologists consider the anterior parts of the frontal lobe to be the region in which is located the control of the intellectual faculties. Halliburton, however, and certain others locate the intellectual faculties in the occipital lobes, stating that experimental physiology lends no support to the view that the frontal brain is the seat of the intellect. Crochley Clapham also strongly supports the occipital theory of the seat of intelligence, saying that he considers that the evidence scales heavily in favour of the superior intellectual value of the posterior lobes. Others, on the other hand, such as Schäfer, believe that the intellectual faculties are bound up in the integrity of the brain as a whole, basing their arguments on the experimental results in animals. The diverse interpretations of what must be essentially the same post-operative phenomena are explicable in great part by the difficulty experienced in estimating the changes in the exercise of the imperfectly developed faculties of the lower animals and in part perhaps in distinguishing movements controlled by the higher or lower centres. The weight of authority, however, seems to support the contention that destruction of the prefrontal lobes is followed by mental decay.

Returning to the evidence afforded by clinical observation we find that opinion again is divided. Welt collected 59 cases of injury confined to the frontal region in man. 47 of these (80 per cent) showed no change in intellectual capacity or character and only 12 of the total (20 per cent.) had changes recorded against them. Phelps most strongly upholds the view that injuries to the left frontal lobe alone give rise to traumatic insanity; brained in intellectual faculties His conclusions are founded c frontal lobe, in which the conditions allowed an estimate of the direct results, apart from those due to other intracranial lesions coexistent. He has recently recorded a further list of 18 cases supporting the theory that lesions of the left frontal lobe are followed by mental changes, whilst lesions to the right frontal lobe are innocuous. Analysis of his original 28 cases gives the following results: 1. In 11 cases injury was confined to the left lobe, frontal laceration. Mental aberration or deficiency was present in every one apart from mere stupor or delirium. 2. In seven cases laceration was confined to the right lobe. There were no mental changes. 3. In ten cases both lobes were involved. Mental changes due to implication of the left lobe were present in eight. One patient died too early and in one inexplicable case there were no changes. The resulting mental changes varied somewhat with the situation of the laceration. In subcortical lacerations the patients' con- abrogation of the mental power occurred, dition being sluggish and apathetic; whilst with cortical lacerations there was alteration of the mental powers—per- verted memory, lack of attention and concentration, incoherence, delusions, or the stupor of confusion rather than that due to paucity of ideas. He found further that compression and contusion only exceptionally produced specific intellectual changes and that there was no instance in which laceration in any other part of the brain produced characteristic mental effects.

In regard to my own cases you will notice that the boy shown to-day was injured in the left frontal region. In my four cases of direct traumatic insanity the injury involved the parietal region in two cases and the base of the skull in the other two. In summing up the evidence presented both by physiological experiment and by clinical observation I believe that the question must at present remain unsettled; it is not yet known whether injury to the frontal or pre frontal lobes is more likely to be followed by special mental disturbances than injuries to other parts of the brain and I believe that the problem will ultimately be solved by extended clinical observations rather than by experimental physiology.

Morbid anatomy.—In cases of direct traumatic insanity examined after death or relieved by operation lesions of the most varied kinds have been found. Of the local changes the one which has excited most interest from the surgical point of view is depressed bone, for here is a clear indication for operative measures and greater success has been obtained in such cases. Amongst the other local changes found are adhesions of the membranes to the bone or brain, cysts of hæmorrhagic origin, either on or beneath the dura mater or cortex, thickened and hyperæmic bone, necrosis, adherent pericranium, and unsuspected foreign bodies. The important point is that most of these lesions are superficial and therefore within reach of the surgeon.

With the depressed bone may be associated splinters from the internal table pressing on, or wounding, the dura mater or the brain and osteophytic growths. The latter are not at all uncommon in these cases and are probably the result of local traumatic meningeal inflammation. They may occur when there is no depression of the bone whatever but are most marked when resulting from the constant irritation of depressed fragments. The importance of arachnoid cysts in the etiology of insanity has been long recognised. Quain related a case of a patient who suffered from melancholia, irritability, and fits which were found due to a large loose arachnoid cyst. It has sometimes been found that the moveable cysts were associated with attacks of acute mania, possibly due to the cyst altering its position. Amongst the more general changes we find sclerosis of the brain tissue accompanied by cerebral softening. There is usually a diffuse degeneration of certain parts of the cerebral cortex starting from the point of injury and leading to a true cirrhotic atrophy Powell states the situation of the lesion in 67 cases of operation for traumatic insanity: the parietal and interparietal regions were involved in 41 cases, the frontal in seven, and the fronto-parietal in five. The preponderance of the parietal regions is, of course, mainly due to their large area. A notable point is the relatively small number of cases in which the frontal region, a locality easily accessible to operation, was involved.

Traumatic insanity is frequently associated with traumatic epilepsy and the two conditions present many points of similarity in their etiology, morbid anatomy, and course. Further, just as epileptic convulsions may occasionally be produced by pressure applied to a sensitive scar, so may psychical phenomena such as delusion be called into existence by like pressure. But the relation of the two diseases is not that of cause and effect, they are rather two distinct affections the effects of a similar cause. Where the two coexist insanity most commonly follows epilepsy, but one frequently exists without the other and traumatic insanity may precede, or run concurrently with, traumatic epilepsy. It is now recognised that general paralysis of the insane is due in a certain number of cases to head injuries, but the proportion of traumatic cases is variously estimated by different authors. Thus Crichton-Browne found three traumatic cases in 42. L. Meyer states that 11 out of 60 cases were traumatic and Christien gives 47 in 104 cases In the Devon County Asylum, between 1845 and 1870, there were 344 cases of general paralysis, in 103 of which the cause was ascertained; of these 12 were the result of head injuries. Clouston considers that the cases in which the changes exactly resemble the motor symptoms of general paralysis are not progressive and that he saw only one case of real (progressive) general paralysis following traumatism. Risien Russell states that he believes that injury is a very common cause of general paralysis but only in predisposed persons. He could not recall a single case of insanity due to injury pure and simple which turned out to be general paralysis

I propose to refer somewhat fully to a case reported by Mr. A. Marmaduke Sheild and Dr. T. Claye Shaw, in which symptoms of early general paralysis of the insane followed a head injury and in which the symptoms completely disappeared after removal of depressed bone. The patient, a man aged 30 years, had been thrown from a dog-cart and sustained a scalp wound in the left frontal region below the frontal eminence. He was also concussed but only confined to bed for a short time. The bone was carefully examined and was apparently uninjured. About a month later serious mental symptoms commenced. His wife and friends noticed an alteration in his manner and temper. He exhibited sudden and violent outbursts of temper and became quite unfit to carry on the ordinary business and duties of life. After rest and treatment he became better for some weeks, but on resuming a more active life the old symptoms returned with increased violence. He was examined by Dr. Claye Shaw three months after the injury and the following is a brief summary of his remarks: "The patient wore a confused and demented facial expression and had a considerable amount of facial and general tremor. He was unable to stand firmly with his feet together; reading was *extremely difficult*, and the handwriting *was deciphered* with difficulty owing to the crowding of the letters and the shakiness of the upstrokes. The prominent mental condition was one of dementia, but there was an unwarrantable *bien-être;* no illusions could be elicited. There was no history of alcoholic excess or of syphilis and the symptoms appeared directly traceable to the head injury." Trephining was recommended and was performed by Mr. Sheild on the following day. When the bone had been exposed and examined critically a faint crack was seen. On removal of a crown of bone a fracture of the inner table was apparent and two small pieces of bone which were depressed deeply upon the dura mater were removed. Prompt and complete recovery resulted. The case illustrates the excellent results of early operation in cases where the mental symptoms are distinctly referable to the injury.

Treatment.—Traumatic insanity is the only form of insanity which may be rationally treated by trephining and this only when other causes can be excluded and when localising symptoms are present, such as cicatrices, depressed bone, or a circumscribed area of tenderness. Only a small proportion, therefore, of the cases of traumatic insanity are open to relief by operation, for it is essential that some localising indication of a lesion should be present which can readily be reached to justify surgical interference. The prognosis in any case apart from operation is most unfavourable. The disease may follow one of two courses—it may persist indefinitely or it may steadily progress, ending either in dementia or in inflammatory changes which may ensue suddenly after a long period, causing coma and rapid death.

In suitable cases with obvious injury trephining may cut short the mental symptoms by removing the cause where there is no accompanying deep-seated sclerosis of the cortex. Operation will be contra-indicated when the mental disturbance follows a fracture of the base, as is not infrequently the case, the lesion being then inaccessible; and when there is extensive damage to the brain, so that its functions have been directly and permanently interfered with; and when general intracranial changes have taken place. For such cases as these but little can be expected from operative interference. On the other hand, where we have some local indication in an accessible region, more especially if this be depressed bone or tenderness localised to the neighbourhood of a scar, then operation may be performed with some hope of success. A free opening should be made into the skull and any lesion dealt with according to circumstances. Even if nothing abnormal is found at the seat of injury the operation will not necessarily be unsuccessful, for undoubted cases have occurred in which good mental recovery has followed although no local lesion has been found. This fact, of course, must not prevent in any way a very thorough search.

The prognosis of operative treatment may be judged to some extent by Powell's cases, but, as he mentions, the results so obtained are far too encouraging. In summing up the results in his series of 62 cases in which recovery took place we find that there were 41 cases of mental recovery, 12 of great mental improvement, five of slight improvement, and only four in which no permanent improvement to the mental state was recorded.

CONCLUSIONS.

1. Whilst some degree of mental impairment is comparatively common after injuries to the head the changes are seldom sufficiently marked to be included under the heading of insanity.
2. Insanity may result from injury to any part of the head.
3. Traumatism leads to insanity in two ways: (1) direct insanity due to the actual injury to the brain or its membranes apart from hereditary or other predisposing causes; and (2) indirect insanity—that is to say, any form of insanity occurring as the result of lowered resistance of the brain due to injury in patients with a predisposition to insanity, hereditary or otherwise.
4. Every variety of mental change may be produced by traumatism, although some forms are commoner than others.
5 It is at present undetermined whether injury to the prefrontal region is more likely to be followed by mental disturbances than injury to other parts of the brain.
6. Only a small proportion of the cases of traumatic insanity are open to relief by operation, for a localising indication in an accessible region must be present.
7. The results so far have been encouraging and although the operation must necessarily be exploratory it is fully justified in suitable cases, especially in face of the otherwise hopeless condition of these patients.

THE ANTI-MALARIAL OPERATIONS AT MIAN MIR (PUNJAB).[1]

BY J. W. W. STEPHENS, M.D. CANTAB.,
WALTER MYERS LECTURER ON TROPICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

ALTHOUGH the final report on these operations is not yet issued, this report of Captain S. P. James, I.M.S., enables us to judge of the results achieved and unless the final report is very different in character we shall not be far wrong in summing up on the evidence we possess. My excuse for writing on this subject is that I know Mian Mir well, being at first myself engaged in the preliminary malarial survey previously to the operations subsequently carried out by Captain James. Had I taken any part in the actual operations I should have refrained from estimating the value of the results, but as my connexion with the scheme was only an initial one I am able to take the position of an unbiased observer. At the outstep it is, I think, only fair to point out a misconception that has arisen as to the choice of Mian Mir as a suitable place for *anti larval* operations. When Dr. (now Lieutenant) S. R. Christophers and myself arrived in India and had determined to test the efficacy of anti-larval measures as a means of abating malaria we consulted those in authority as to a suitable station. Our requirements were, first, a station markedly malarial, so that there might be no doubt of the result of the measures if successful; and, secondly, a station which was dry—i.e., one where we should not have to undertake such tedious and expensive measures as drainage. Mian Mir appeared to meet these conditions, but it was only on reaching Mian Mir and inspecting it that we found that this apparently dry station (the rainfall is only 20 inches) was one of the wettest we could have chosen, for the cantonment was covered with a network of irrigation canals; in fact, there was water everywhere. At the last hour we would have withdrawn could we have found the conditions we required but this seemed at the time impossible from the information at our disposal; and looking back I cannot think the choice in some respects was unfortunate, for when we consider this report we shall at least convince ourselves that these measures are not to be undertaken lightly or without an appreciation of the great amount of work involved. What in the case of Mian Mir this actually meant in desperate hard work only those who know the climate of this "terrible" place can fully appreciate.

Before actually discussing this report I may recall what had been the conclusions of Lieutenant Christophers and myself in Africa as to the measures necessary for malarial prophylaxis. We had been convinced that the fundamental method in anti-larval measures was drainage—necessarily an expensive though an effective and permanent remedy. In Freetown, Sierra Leone, this method seemed to us the only one applicable to the suburbs or outskirts of the town where the "endemic index" of the children was high. The central portion of the town situated on sloping ground, with large houses and open streets fairly well drained was, we found, quite free from anopheles, as we showed by the use of "test pools," and in fact we never captured insects in this portion of the town though existing in myriads half a mile away. Tower Hill barracks and Government House are also areas completely free from anopheles, though they abound a quarter of a mile away. These seemed to us most important facts as they showed that even a slight measure of separation or segregation from the huts of the natives was here at least an efficient protection against the anopheles. It is true that the West Indian troops at Tower Hill suffer from malaria but the explanation is simply that the men constantly visit their wives and women folk in the huts of the outskirts where malaria is rife. Two convictions then impressed themselves on us as the result of our observations in Freetown: (1) that protected areas—e g., central Freetown and Tower Hill—may exist in the midst of areas rife with malaria; and (2) that the reduction of the endemic index of outer Freetown—i.e., the true native quarters—would involve extensive drainage works. I may recall also the conditions we found at Accra, Gold Coast, for they were very different from those of Freetown. Suffice it to say that here we were again struck by the protection enjoyed by the officials who for the most part lived in a segregated area—that is to say, their bungalows were well removed from the na
population living amidst
Finally, in Lagos we
measures could be simpl
concluded that by filling
the breeding places in Lagos could be abolished. It does not concern us here to inquire what measures have been taken in these places, but there is one further point which impressed itself upon us very forcibly and that is that before any measures of any kind whatsoever were undertaken it was necessary to know exactly to what extent malaria prevailed in the particular place. For if we know the intensity of malaria in any place we can then ascertain if it decreases as the result of prophylactic measures. Now the intensity of malaria, or, as we called it, the "endemic index" of a place, can be easily and accurately determined. It is only necessary to examine a number of blood films (25 is sufficient) taken from the children (under ten years of age) from any district to give us the percentage of those with parasites in their blood—i e, the endemic index. We have in this figure a true test of the intensity of malaria in any place and, knowing this, we are in a position to determine exactly the result of prophylactic measures.

Turning now to Captain James's report we find that he rightly claims that these operations are the first where not only were all other conditions first determined by an exhaustive "malarial survey" but in addition the malarial index of all the native quarters (bazaars) was determined before the commencement of operations. These figures, as we shall see from this report, form a most valuable and sensitive test of variations in malaria. Not only was this done but these experiments were characterised by the care taken to have adequate controls. How essential this is will be seen later where entirely false conclusions might have been drawn had not this been the case. Before commencing operations, then, a minute survey was first made of all breeding grounds, of the species of anopheles present (a very important matter), and of the particular breeding ground of each species. It was found that *M. culicifacies*, which is the carrier of malaria in Mian Mir, bred almost exclusively in the irrigation canals and it was the destruction of the larvæ of *M. culicifacies* in these canals that was the most important part of the operations. But in addition all breeding grounds were so treated by filling up with earth, draining, baling out, "oiling," &c, that it could be safely said that after a time no possible source of larvæ had been overlooked. The operations were commenced in April, 1902, and were prosecuted with such vigour by Captain James that a distinct decrease in the number of anopheles occurred during the summer. They still could be found in November but in December they had completely disappeared. A satisfactory result, one would at once say, were it not that Captain James had made control observations and in the *untreated* areas a similar disappearance occurred, so that the operations could not be credited with the result. This was in December, 1902. Adult anopheles had vanished but still larvæ could be found here and there in the canals "hibernating"—i.e., alive but not growing and changing to pupæ. It was Captain James's aim now to destroy these hibernating larvæ by the use of oil and other methods, with the result that at the end of the winter no larvæ could be found within a radius of two miles of the centre of operations. This happy result could not, however, be maintained, for with the onset of the hot weather in April, 1903, larvæ were again found. What was the origin of these larvæ? Captain James is of opinion that they were brought into the area of operations by the flowing water in the canals. That larvæ are so washed in we had early observed at Mian Mir. Here, then, was a serious difficulty in having always a fresh supply of larvæ washed down the canals from outside. This was one method by which the anopheles were increased, but it appeared also that insects came in by flight from outside districts and possibly by flying as far as one to two miles; and thirdly, there was a gradual and increasing filtration into the area from house to house and breeding place to breeding place. In these three ways the anopheles may have increased but to apportion to each of these its right value is a matter of great difficulty. This increase by flight and by "filtration" is difficult to understand and appears to be exceptional, for our experience in Freetown and Accra was the opposite and, indeed, in this report an experiment is recorded where a "segregated" camp was established three-quarters of a mile from any breeding ground with the result that there was a complete absence of anopheles in the camp. To the flow of the water in the canals I should be inclined to attribute a greater part of the increase, but Captain James's views as to flight and "filtration" cannot be lightly passed over. Anopheles were also constantly introduced in carts, wagons, and conveyances of various kinds. In April, 1903, then, anopheles had reappeared in that portion of the cantonment in which operations had been conducted for the space of a year. The operations were, however, continued for yet another year with all the advantages gained from a year's experience and in July, 1903, Lieutenant Christophers took charge of the proceedings. The measures were of the same kind but were now extended to a distance of three-quarters of a mile from the Royal Artillery bazaar, practically the centre of the area under treatment. Although the effect on the larvæ was distinct yet the increase in the adult insects could not be checked, due again apparently to "filtration" from outside the area. We think that the result may be fairly summed up by saying that the anti-larval measures were to a certain extent successful but that no check could be placed on the number of adults.

rt of the anti-malarial
operati
P. James, I.M.S. Our
review

Let us now turn to the effect upon the malaria of the cantonment. As regards the effect on the malaria of the troops one must admit that the result was extremely disappointing. Without entering into details it will suffice to say that though at first there was some check as the result of these measures, yet as the "fever season" advanced malaria became rife and the practical outcome of two years' persistent work as measured by this test was *nil*. Let us now turn to the malaria in the bazaars. The figures for 1903 are not yet published but those of 1902 are of extreme interest as showing what a sensitive test the endemic index is and in this connexion we may consider also two most interesting experiments made in prophylaxis—viz., (1) the administration of quinine to the native children and (2) segregation of an infected community of native children. The results will be evident from the following table:—

Bazaar.	Measures carried out.	Endemic index, October, 1901.	Endemic index, October, 1902.
British Infantry	None (control).	52·0	42·3
Royal Artillery...	Destruction of larvæ.	35 0	20 0
Syce lines A ...	Segregation.	56·5	4·0
Syce lines B ...	Administration of quinine.	20·0	0·0

We see that the endemic index of the Royal Artillery bazaar in October, 1901, was 35 per cent. In October, 1902, it was 20 per cent.—a considerable reduction and at first sight due to the operations; the control observation, however, showed that in an untreated area there was likewise a reduction due to unknown factors, but a closer comparison shows that in the area of anti-larval operations the decrease was greater than in the control area, 1·75 to 1 in the first case, 1·23 to 1 in the latter, a difference which may fairly be attributed to the credit of the anti-larval measures. In the last line of the table we have the result of the administration of quinine throughout the year, a reduction of 20 per cent to 0 per cent, a most striking and satisfactory result. Equally striking was the result of removing the whole of the "Syce lines A" to a distance of three-quarters of a mile from the nearest breeding grounds. The great decrease from 56 per cent. to 4·0 per cent shows in a convincing way the beneficial effects of segregation and in this method—viz., the removal of an obvious source of infection—we have a valuable means of ameliorating the condition of a cantonment, for it is obvious that the risk to the troops must be less if a constant infecting focus—viz., a number of native children—is at a distance of half a mile or a mile instead of a stone's throw away. The experiment was also tried of administering quinine to the troops under the strictest medical supervision to insure that the quinine was really taken. The result was striking. Only two out of 82 who had taken the quinine were admitted for malaria, while out of 360 who had not taken it there were 67 admissions. The experiment was then extended to the whole of the British infantry; a diminution also resulted but it was not nearly so marked.

To sum up, then, we may say that we agree with the opinions expressed by Captain James that (1) in quinine administration to the children in the bazaars and (2) in the segregation (or abolition) of infecting sources, a method first advocated by Lieutenant Christophers and myself when in Africa, we have valuable means at our disposal for improving the health of the troops. Finally, with regard to the anti-larval measures which it was the special object of these experiments to test, it must be admitted that in this case they have not succeeded in reducing the number of mosquitoes, but the test has been exceptionally severe owing to the unfortunate presence of the irrigating canals in the cantonment. Under the existing conditions in Mian Mir anti-larval measures have proved futile. The malaria problem in Mian Mir must then be attacked in other ways. By quinine administration to the children of the bazaars and by removal to a distance (segregation) of the bazaars (and we understand that this latter is now being carried out) much can be done But finally we should imagine that some fundamental change will also be necessary in the system of irrigation, for, in a word, it is the canals that are responsible for the malaria of Mian Mir. Abolish the canals and Mian Mir would become a sun-parched desert. If this is an impossible plan some radical change in the construction of the canals, so as to permit of their being emptied rapidly and completely as suggested in a footnote by Captain James, would appear to be the only other alternative.

What, then, is the conclusion to be drawn from these experiments? Not as would at first appear natural, that anti-larval measures are useless, for the evidence—e.g., of the operations at Ismailia and, indeed, of this report—by no means supports this conclusion, but that great care should be taken in the choice of a suitable station. Finally, in attacking malaria where anti-larval measures are for any reason impossible, we still have two powerful measures at our disposal—viz., quinine and segregation.

ROYAL PORTSMOUTH HOSPITAL.—The fifty-fifth annual meeting of the supporters of this hospital was held at the town-hall, Portsmouth, on Jan. 23rd, Sir John Baker presiding. The total number of in- and out-patients treated during the year was 11,784, as compared with 11,564 in 1902. It was stated that owing to the energetic efforts of the ex-mayor, Major Sir W. T. Dupree, donations amounting to £2672 8*s.* 7*d.* (thus wiping out a bank overdraft of £1921 5*s.* 6*d.* and adding £751 3*s.* 1*d.* to the income for the year) and new and increased subscriptions amounting to £616 4*s.* 6*d.* had been received. Notwithstanding these amounts obtained through the mayor's fund there was a deficit of £637 on the working during the year. A proposal was made to proceed with the rebuilding of the hospital by the erection of a new block of wards.

MOTOR SYMPTOMS OF MANIA AND MELANCHOLIA;

WITH A THEORY OF THEIR ORIGIN AND OF THE ORIGIN OF DELUSIONS ARISING IN THESE CONDITIONS

BY W H B STODDART, M D, M R C P LOND,
ASSISTANT MEDICAL OFFICER BETHLEM AND BRIDEWELL ROYAL HOSPITALS

"EVERY phenomenon is best studied where it exists in the greatest intensity It is there that the effects which either depend on it, or depend on the same causes with it, will also exist in the greatest degree It is there, consequently, and only there, that those effects of it, or joint effects with it, can become fully known to us, so that we may learn to recognise their small degrees, or even their mere rudiments, in cases in which the direct study would have been difficult or even impossible Not to mention that the phenomenon in its higher degrees may be attended by effects or collateral circumstances which in its smaller degrees do not occur at all, requiring for their production in any sensible amount a greater degree of intensity of the cause than is there met with" Thus wrote John Stuart Mill in Book IV of his "System of Logic" The
able than in th
investigation c
it is there that we shall find characteristic symptoms most marked Knowledge gained by such investigations may then be used for the study of milder cases of the same kind

Some years ago I drew attention to the fact that melancholiacs suffer from paralysis and rigidity of the muscles of the spinal column and of the large proximal joints, the movements of the wrists, fingers, ankles and toes being comparatively unimpaired It appears that a certain amount of scepticism still exists in the minds of some observers with regard to the accuracy of my observations and I venture to suggest that such scepticism has arisen from neglect of the above principle of investigation Observers have endeavoured to discover paralysis and rigidity in the milder cases of melancholia and have failed to do so because these symptoms are very slight in mild cases Indeed, in the lesser degrees of melancholia slight paralysis has to be inferred from the patient's slowness of movement and from his inability to occupy himself in any way It is only in the severest cases that there are obvious well marked paralysis and rigidity, but these are the cases which should be studied first

The coexistence of paralysis and rigidity is a common occurrence in disease of the nervous system Paralysis and rigidity coexist in melancholia but the rigidity is more easily investigated than the paralysis To recapitulate my previous observations, rigidity is most marked in the muscles of the trunk and neck, less marked but strikingly present in the shoulders and hips again less marked at the elbows than at the shoulders, less marked at the wrists than at the elbows and usually absent from the fingers Similarly, rigidity is less marked at the knees than at the hips, very slight at the ankles and usually absent from the toes The rigidity affects flexors more than extensors and adductors more than abductors, hence the attitude of the melancholiac is one of general flexion and adduction, the shoulders being raised owing to the rigid contraction of the upper part of the trapezius I have called the condition *proximal* rigidity in contradistinction to *peripheral* rigidity such as occurs in hemiplegia where the fingers and wrists are most affected

In making observations on the above points voluntary resistance to, or assistance in movement of the limb must be discounted, and it is further to be observed that, as in paralysis agitans, rigidity disappears from a joint after three or four passive movements For this reason it is difficult to demonstrate the rigidity to a class of students The paralysis is most easily studied where it is most intense—viz, at the large proximal joints. It is difficult to detect at the elbows but it is easily observed at the shoulders by asking the patient to hold the hands straight above the head In a severe case the patient cannot raise the elbows above the level of the shoulders In severe cases of melancholiac stupor the patient stands in an attitude of general flexion with adduction and there is complete absence of voluntary movement (Fig 1) But if there is associated with the melancholia some degree of restlessness or agitation, this naturally shows itself in those movements which are least paralysed—viz, in movements of the wrists and fingers, ankles and toes In other words the patient stands (for the rigidity at the hips renders sitting an uncomfortable posture for melancholiacs) rocking the body from foot to foot by alternate flexion and extension of the ankles while constantly picking the skin of the fingers or fumbling with the clothes, the fingers are in constant movement (Fig 2) I

FIG 1

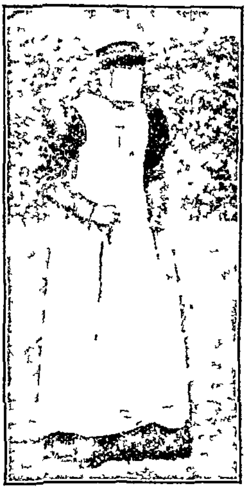

FIG 2,

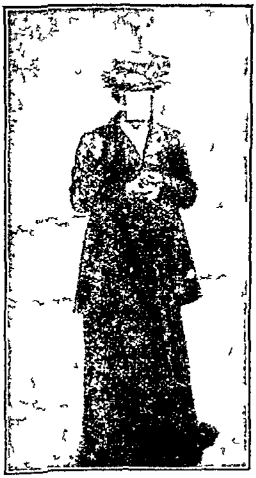

the agitation is yet more marked it shows itself in grosser movements of the hands and feet, the the
ht
hands and some cl

movement at the knees may contribute to the rocking movement. In a few cases of melancholia in which the rigidity is sufficiently slight to allow the patient to sit with comparative ease, a to and fro rocking movement takes place at the hips as well as at the small joints. In all these cases, however, it is to be observed that the restlessness shows itself most in peripheral activity.

The movements of mania contrast very strikingly with those above described. Observations on movements of the insane in general and of maniacs in particular are best made on female patients in the airing court, because females react more readily than males to ordinary stimuli and because movements are less restrained when the patient is in the open air. The movements of a maniac in a state of motor excitement[1] take place for the most part at the large proximal joints (Fig. 3). The trunk sways freely as the patient walks and when she runs there is exaggerated movement at the hips, whereas in the running of a sane woman there is little movement at the hips. In the waving of the arms, which is a frequent occurrence in mania, the greatest movement takes place at the shoulders and there is little movement of the wrists and fingers. The maniac shakes hands from the shoulder (Fig 4), the melancholiac from the wrist (Fig. 5). In the maniac the attitude of prayer is with the hands upraised to heaven, in the melancholiac the attitude of prayer is with the hands clasped in front of the sternum. The typical attitude of the melancholiac is with the elbows close to the side, that of the maniac is with the elbows away from the side.

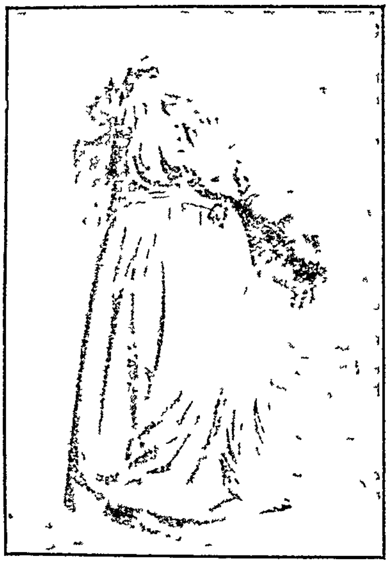

FIG. 4.

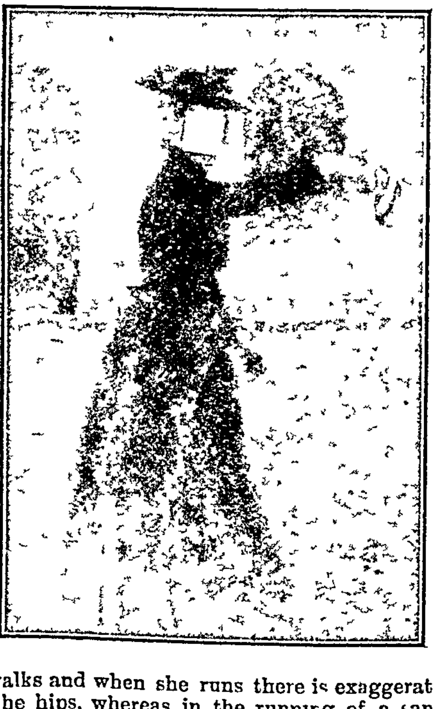

FIG. 5.

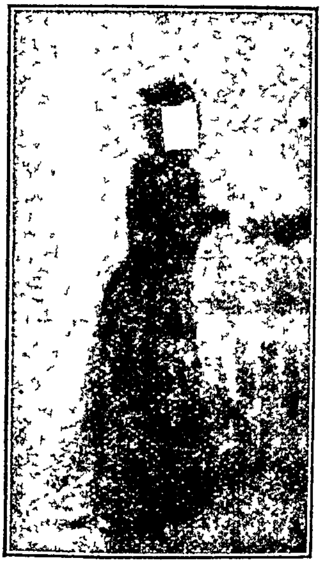

Correlated with these observations, there is an interesting one in the domain of experimental psychology. If the arm of a normal individual in an indifferent mood be allowed to rest upon an automatoscope (an instrument of the nature of a planchette but of more convenient shape), it is found that the instrument records on the paper a slight normal tremor of the arm. If now the individual receive an unpleasant stimulus—e.g., the smell of assafœtida—slight *adduction* of the arm is noticed and recorded by the instrument. If, on the other hand, the experimenter give a pleasant stimulus—e.g., the smell of heliotrope or white rose—slight *abduction* of the arm is noticed and recorded by the instrument.

I have so far attempted to demonstrate that characteristic movements of melancholia occur at the small peripheral joints and that characteristic movements of mania occur at the large proximal joints. I must, however, here call attention to a special variety of mania which does not at first sight appear to fall in line with the cases of mania above referred to. Some cases of acute mania have peripheral movement as well as proximal. These cases are not very frequent but they are usually very severe. The patient is, as a rule, too ill to be allowed out of his room. He crawls about on all fours and persistently polishes the floor with his fingers. If the patient lies on his back the arms are abducted and the legs are extended. Movements when present may be observed in both proximal and peripheral joints. Many of these patients die They appear to be unable to withstand the most trivial intercurrent physical disease an acute sore throat or a trifling attack of diarrhœa being in some cases sufficient to carry the patient off I have however, seen several such cases recover with very little dementia Although these patients, have both large and small joint movements the large joint movement is in excess, so that there is no difficulty in recognising them as cases of mania.

Having regard to the generally accepted view that insanity is due to some nutritional disturbance of the cortical neurons, I think that the observations above described suggest a possible explanation of the phenomena of mania and melancholia This explanation depends upon Dr J Hughlings Jackson's hypothesis that the slow proximal movements of large joints are represented in the cortical motor areas in large nerve cells and the rapid peripheral movements of small joints in small nerve cells Now the nutrition of a cell may be disturbed in one or more of four different ways: (1) the cell may contain an irritating stimulating body; (2) the cell may contain a depressing paralysing body; (3) the plasma surrounding the cell may contain an irritating stimulating body; and (4) the plasma surrounding the cell may contain a depressing paralysing body. Now it is to be observed that, with regard to their cubical content, small bodies have a large relative surface and large bodies have a small relative surface. The large cells of the cortex representing proximal movements have a smaller relative surface than the small nerve cells representing peripheral movements. Let us now consider how these cells would be relatively affected by the four above-mentioned conditions of disturbed nutrition. If an irritating stimulating product were formed within the cortical neurons the result would be general motor activity affecting the proximal movements most, because the large nerve cells in which proximal movements are represented have a relatively small surface by which they may get rid of the deleterious substance, while the small cells would readily excrete it from their relatively large surface. If, on the other hand, a depressing paralysing product were formed within the cortical neurons the result would be weakness or paralysis affecting the proximal movements most, for similar reasons. The same argument applies if the depressing influence within the nerve cell be deficiency of nutrient matter (trophoplasm); the large cells again suffer most because they have the smaller relative surface by which they may absorb nutrient matter [illegible] ma [illegible] a [illegible] nts [illegible] most, [illegible] pheral [illegible] the de [illegible] r similar reasons, if the plasma contained a paralysing body or its equivalent (deficiency of normal nutritive and stimulating bodies) there would result a paralysis affecting the peripheral movements most. The first condition (general motor activity affecting the proximal movements most) is, I have submitted, that which occurs in mania. The second condition (proximal weakness or paralysis) occurs in melancholia, especially in the more stuporous forms. The third condition (peripheral activity) is met with, as above stated, in cases of agitated melancholia and is also occasionally superimposed in mania upon the typical proximal activity. The fourth condition (peripheral weakness) is rarely, if at all, met with in cases of insanity except as a result of coarse brain disease.

---

[1] A maniac is not always in a state of motor excitement, he has his periods of rest But here, as elsewhere, symptoms are to be studied when and where they are most intense.

The above considerations appear to suggest that we may form the following *conclusions*: (1) that in mania an irritating product is formed within the cortical neurons—such a view is further supported by the frequency of hallucinations in mania; (2) that in melancholia a paralysing product is formed within the cortical neurons; (3) that in agitated melancholia there is a combination of *deleterious influences*—viz, a paralysing product within the cortical neurons and also an irritating body in the plasma which bathes the nerve cell; and (4) that in a few cases of mania there is in addition to the irritating body within the nerve cell an irritating body in the plasma which bathes the nerve cell Whether we are to imply from the above considerations a new formation of cytotoxins or an increased formation or deficient elimination of substances which normally occur in the *organism* there is at present no evidence to show, but as regards melancholia it may be well to bear in mind the old observation that in that disease there is a general tendency on the part of the cells throughout the organism to fail in the excretion of their normal metabolic products.

Origin of the delusions.—When once the fact is grasped that melancholia is a special form of paralysis it is easy to see in what way many of the more common delusions of melancholiacs arise. Although the melancholiac suffers from paralysis he does not realise that he is suffering from paralysis; he only realises that he is unable to do things which formerly were easy to him, and he naturally begins casting about for a reason for this change If he comes to the conclusion that his condition is of the nature of an illness he does not suffer from delusion and is accordingly a case of "simple melancholia." If the patient is a spiritualist, if he believes (as most people do) that there is an immaterial ghost pervading the organism, a ghost spirit, or soul, which is not mind and which initiates all his actions, then when he finds that he is unable to perform those actions his natural conclusion is that his soul is lost. Following up this train of thought he gets the idea that he is deserted by God, eternally damned, and *cannot recover—that he has committed the unpardonable sin.* In this *frame* of mind the patient may fix upon some past peccadillo as the cause of all the mischief, or by a process of simple paramnesia he may even falsely accuse himself of some dreadful crime. He may, for instance, *falsely* accuse himself of having swindled his firm, &c. Other patients, starting with the same premiss, regard their *inactivity* as a loss of vital energy and so come to the conclusion that they are dead Others, again, with less definite ideas, at first merely believe that they are altered in some way; these patients subsequently develop most grotesque delusions about the nature of the change. For example, one female patient at present in Bethlem Hospital has come to the conclusion that she is a chicken. At first she merely thought that she was changed, but one morning two of the symptoms of melancholia so forced themselves upon her that she there and then concluded that she was a chicken. These *symptoms* were (1) the harsh dryness of the skin and (2) the position of the arms which were rigidly adducted to the side and flexed—a position roughly suggesting that of a chicken's wing. *Occasionally the peripheral movement gives* rise to delusion, as in the case of a male patient whose ankle movements were so gross as to give him the feeling of being thrown forwards on to his head; hence he has developed the delusion that he is upside down. If I take hold of his foot and ask, "What is this?" he replies "My head"

With another class of patients (hypochondriacal melancholiacs) the weakness, although general, appears to attract the patients' notice locally. For example they exaggerate the weakness of the legs and develop the delusion that they are unable to walk or to stand, or that their legs are brittle and hence made of glass. Other patients of the same class suffering from the epigastric sensation in addition to their paralysis get the idea that their breath has all gone or that their bowels are permanently blocked up. The obstinate constipation, which is caused not only by the weakness of the abdominal muscles but also by the lack of intestinal secretions, also assists in the development of this last delusion. Closely allied to the ideas of bowel obstruction are such *ideas as that of the throat being blocked up* and of the food going up into the head.

In all the above cases the patient merely takes account of his own weakness and blames nobody but himself for his condition But if he is normally of a suspicious nature, or if he suffers also from hallucinations or illusions, he is apt to ascribe his condition not to his own weakness but to the increase of resistance in his environment. Hence arise all kinds of delusions of persecution. Such patients believe themselves to have been changed by some hostile person or persons by means of some occult influence [illegible] More usually they have delusions of [illegible] ions from [illegible] into their [illegible] their food [illegible] hallucina[illegible]tion), and so forth. Most of these patients are cases of dementia paranoides. Cases of true paranoia must be excluded from this category; the delusions of the paranoiac [illegible] different manner [illegible] show that most of the [illegible] rise from his feeling of [illegible] exaltation of the maniac arise in a corresponding manner from the feeling of activity which arises from the stimulation of his cortical neurons. The maniac during an attack of motor excitement feels strong and capable of the most wonderful athletic feats. Hence arises the general idea of power and the patient develops the delusion that he is a duke, lord, king, or God, or that he is possessed of untold wealth The development of delusions of this kind, however, is very often disturbed by the frequent occurrence of hallucinations, so that the feeling of activity is thrown into the background by perversions of the senses.

The above outline *of the mode of origin of delusions* in mania and melancholia is not intended to be a complete account. It is only intended to draw attention to the fact that a large number of these delusions are to be explained by the feelings of activity and inactivity which I submit to be the most important characteristics of the two conditions.

Bethlem Royal Hospital, S E.

FOUR CASES OF TETANUS TREATED BY INJECTIONS OF ANTITOXIN INTO THE SPINAL THECA.

BY CUTHBERT S. WALLACE, M.B., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE EAST LONDON HOSPITAL FOR CHILDREN;
AND
PERCY W. G. SARGENT, M.A., M.B, B.C. CANTAB., F.R.C.S. ENG.,
RESIDENT ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL.

THE treatment of tetanus, especially in its acute form, is so unsatisfactory that any new departure, however slight, is of interest and value. We have therefore thought it worth while to put the following cases on record. For permission to make use of Cases 3 and 4 we wish to acknowledge our thanks to Mr. H. H Clutton and Mr. G. H. Makins, under whose care they were admitted.

The method adopted was the injection of antitetanic serum (supplied by the Lister Institute) into the spinal theca The strictest aseptic precautions were observed and the serum was injected by means of an antitoxin syringe, provided with a specially long needle, introduced between the third and fourth lumbar laminæ. In no case were any illeffects observed, either immediately or at a later period. This method was first practised by Professor von Leyden.[1] In his case two injections of ten cubic centimetres each were given, a corresponding quantity of cerebro-spinal fluid being withdrawn. The patient recovered. Penna[2] records five cases treated in this manner, with three recoveries. The injections varied from a total of from 100 to 240 cubic centimetres of serum, as much as 60 cubic centimetres being used at one sitting, and a corresponding quantity of cerebrospinal fluid being always withdrawn. The three cases that recovered had daily injections and the symptoms subsided in from five to 17 days. In the two fatal cases the patients died from pneumonia but the spasms had ceased and the limbs were relaxed and could be moved. In no instance were any bad effects noticed.

The numbers are too small for any definite statement to be made as to the efficacy of the procedure; indeed, it is still doubtful if the intradural method will show any better results than the subcutaneous. Leaving out of consideration for the present any comparison between these two methods there can be very little doubt that the lumbar injection is to be preferred to the intracranial. For the performance of the latter the head must be shaved and the cranial vault perforated with some instrument, whether it be a trephine or a drill. This is very much more complicated than the simple skin incision required for lumbar puncture. The fact that lumbar puncture is frequently used as a means of diagnosis is a sufficient proof of the innocuous nature of the procedure and no bad results have been observed in our cases or in those of other observers.

The incubation periods of the cases here described were respectively three to six, six, nine, and 11 days. Two may therefore be considered to have been acute and two subacute or chronic. Three patients recovered and one died, the fatal case being second in order of severity both as regards incubation period and the character of the symptoms.

CASE 1.—The patient, a female, aged 43 years, fell and cut her head 17 days before admission Nine days later she noticed "stiff neck" and four days after that the jaw began to feel stiff On admission there was a suppurating wound over the posterior part of the right parietal bone. The muscles of the neck, the back, the abdomen, and the face were in a condition of tonic contraction. The temperature was 99° F and the pulse was 100 She complained of a good deal of pain in the back. The first general convulsive attack occurred during administration of chloroform when the scalp wound was freely excised and ten cubic centimetres of antitetanic serum were injected into the spinal theca. Five hours after operation a second convulsive attack took place in which the back was strongly arched and marked cyanosis occurred. There were three more convulsive attacks during the same evening at intervals of two or three hours, similar to, but not so severe as, the first. Urine was voided during the spasms. On the second day four more such attacks were noted in the forenoon, after which no further ones occurred. Owing to the difficulty of introducing food into the mouth, and of swallowing, rectal feeding was employed for the first five days. On the second day she began to swallow milk in small quantities. On the third day chloral and bromide of potassium, ten grains of each, were given every four hours and were continued for several days. Improvement began on the second day and continued without interruption. The temperature varied from normal to 100° for the first six days with one rise to 102° which occurred on the fifth day. 20 days after admission there was still some stiffness in the muscles of the neck. The patient was discharged well on the twenty-fourth day.

CASE 2.—The patient was a male, aged 38 years, 17 days before admission he had torn the nail of the left middle finger. The laceration healed satisfactorily and on admission appeared to be quite healthy. 11 days after the injury he began to have pain and stiffness in the back, which soon spread to the neck, then to the jaws, and later to the face. There had been no convulsive attack. When admitted he was suffering a good deal of pain, particularly in the back. Trismus and risus sardonicus were well marked and there was some degree of opisthotonos, the erector spinæ standing out most prominently. The recti abdominis were tense and hard. The limbs were not affected and the temperature and pulse were normal. Shortly after admission chloroform was administered and the finger was amputated, a small abrasion on the dorsum of the hand being excised at the same time. Ten cubic centimetres of antitoxin were injected into the spinal theca. 14 hours afterwards a second injection of serum was given and a third seven hours later, the same dose being employed each time. Chloral and bromide of potassium, 20 grains of each, were given for the first two days, after which the dose was gradually diminished. Two hours after the first injection there was a slight spasmodic attack in which the back was arched and the jaws were tightly clenched. The patient sweated profusely and complained of difficulty in breathing. Consciousness was not affected. There were two similar spasms during the night and another on the second day. No further spasm occurred until the third day when the passage of a catheter occasioned one. On the evening of the fifth day another spasm was noted, after which there were no more until the ninth day, when four short attacks followed one another at intervals of about an hour. On the tenth day there were two more, of which the second was fairly severe. This was the last that occurred. There was no elevation of temperature throughout, nor did the pulse-rate exceed the normal. Retention of urine demanded the use of a catheter for the first nine days and constipation was obstinate. Food was taken by the mouth throughout. During the third and fourth days hiccough was a marked and troublesome complication but was controlled by small doses of cocaine. The muscular rigidity gradually passed off in the following order—the face, the jaws, the back, the neck, and lastly, the abdominal muscles. When discharged on the twenty-eighth day there was still some slight tenseness of the abdominal muscles. He was seen six months later in perfect health.

CASE 3.—The patient was a male, aged 31 years, who came to St. Thomas's Hospital complaining of trismus of 24 hours' duration His hands were very rough and presented several healed cuts and scratches, all of which had been sustained whilst gardening during the past week. Four days before admission he had driven a splinter of wood beneath the nail of the left forefinger. It was therefore impossible to say how long the incubation period really was or which was the point of inoculation but the time could not have been longer than six days and might have been only three. On admission there were well-marked trismus, retraction of the head, and difficulty of swallowing, but there had been no convulsive attacks. Shortly after admission chloroform was given and the finger was amputated, two healed cuts on the same hand being freely excised at the same time. There was a general convulsive attack at the commencement of the administration of the anæsthetic. Ten cubic centimetres of antitoxin were injected into the spinal theca and 12 hours later a second dose of ten cubic centimetres was given. On this occasion also there was a general convulsive attack as the chloroform was being given. On the evening of the second day the back was more arched, the jaws were more tightly clenched, and well-marked risus sardonicus was present. Chloral and bromide of potassium, 20 grains of each, were now given every four hours and they were continued for 12 days, after which they were reduced in amount and were finally omitted on the twenty-second day. From the third to the sixth days there were frequent slight general spasms in which the limbs remained rigid whilst the back was suddenly arched, the jaws were clenched, and the facial muscles were contracted, each spasm lasting but a few seconds and gradually diminishing in severity. After the sixth day there were no actual spasms but rather momentary twitchings. Food was taken by the mouth throughout, though at times with difficulty. There was no retention at any time, but from the seventh to the eighteenth days there was incontinence both of urine and fæces. The pulse-rate never exceeded 118 and was usually about 90. The temperature ranged from 99° to 101° F. for the first 17 days, on one occasion reaching 103°, but this was fully accounted for by the suppuration of the finger wounds. Profuse sweating occurred during this time. For 26 days the respiration rate varied from 28 to 20 and cough was troublesome, a good deal of viscid material being expectorated, but no physical signs were found in the lungs. From the sixth to the twelfth days he was noisy and delirious and at times quite unconscious, but after the twelfth day the mental condition gradually improved. Muscular rigidity gradually passed off and when the patient was discharged on the forty-second day there was but slight stiffness in the neck and jaws. Seen three weeks later he was in perfect health and showed no muscular rigidity anywhere.

---

[1] THE LANCET, August 31st, 1901, p. 623.

[2] Journal of the American Medical Association, 1902, p. 602.

CASE 4.—The patient was a male, aged 42 years. Six days before admission he sustained a contused wound of the foot with the point of a pickaxe. He was treated at once, the wound being washed out with carbolic acid and dressed with cyanide gauze. Two days later the wound was suppurating. On the sixth day after the injury he noticed some stiffness in the neck and jaws and pain in the back. When admitted there were marked trismus and retraction of the head, the muscles of the neck and back being particularly rigid. The limbs were not affected. The temperature and pulse were normal. Chloroform was given, the wound was excised and swabbed out with 10 in 11 carbolic acid, and a dose of 20 cubic centimetres of antitoxin was injected into the spinal theca. The first general convulsive attack occurred at the commencement of the chloroform administration. On the following day the muscular rigidity was more marked; he complained of a good deal of pain and sweated profusely. There were no general spasms but on attempting to swallow the jaws became more tightly clenched and the head was retracted. He was very restless and slept but little. There was no retention of urine and the bowels acted naturally. The temperature did not rise above 99° F. 12 hours after the first injection of serum a second dose of 20 cubic centimetres was given in the same manner. Death occurred about eight hours later. At the necropsy there was no inflammation of the spinal membranes. No visceral disease was found.

THE ANATOMICAL CHARACTERS OF THE SO-CALLED FILARIA PERSTANS AND ON THE MODE OF INFECTION THEREBY.

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN UNIVERSITY COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC

IN THE LANCET of Jan. 30th, p. 286, I suggested that the so called *Filaria perstans* might really be a species belonging to the genus Tylenchus, while in THE LANCET of Feb. 13th, p. 420, Dr. George C. Low seeks to show that the supposition is not well founded. I further suggested that some such nematoid might be taken into the body either in or with food and that it was not by any means necessary that infection should be favoured by some insect acting as an intermediate host. This view also does not find favour with Dr. Low. He is not correct when he says that my suggestion was "based on a statement made by Christy that the distribution of Filaria perstans in East Equatorial Africa corresponds almost exactly with the area of distribution of the banana and of clothed people, and also on the fact that Bancroft has found a species of Tylenchus infesting the roots of this plant in Queensland, Australia." This statement only covers one-half of the ground on which I based my suggestion. The most important point of all he omits—namely, the alleged fact that the embryo of Filaria perstans as met with in the blood is provided with an oral exertile body which I thought might be similar to that occurring in representatives of the genus Tylenchus and in two other genera of the free nematoids only. There was also the further fact that the members of this genus Tylenchus are capable of surviving prolonged desiccation, so that if present about the banana leaves which are used by the natives of East Equatorial Africa in such *various ways (and especially for plates and* dishes) infection might readily be brought about.

It may be true that the banana is not the source from which infection by Filaria perstans comes. That it cannot be the only source is clear from what Dr. Low tells us, and I am sorry that I should have overlooked his previous paper[1] containing important facts concerning the distribution of the disease. He now says: "In the virgin forests of British Guiana, in areas where there are no bananas, it exists in 50 per cent. of the aboriginal Indians," while speaking generally in his previous paper he said: "So far Filaria perstans has only been found in or near the equatorial belt, where the temperature is high and the atmosphere saturated with moisture, examples of those places being the tropical forests of the Congo and Uganda, where tropical forests alternate with enormous swamps and open ground." These are just such situations in which free nematoids would be sure to occur in the greatest profusion in the earth and about the roots and the lower leaves of plants. It does not, therefore, by any means follow that Dr. Low is right in his supposition that the disease is so prevalent in these tropical forests because there is a "proper intermediate host" for Filaria perstans in the form of some insect which inhabits these areas. This, in fact, is the real point of importance towards which my former note was directed and to which I would again call attention. Must we look for an intermediate host or may no such host be necessary?

Before dealing further with this question, however, a few words must be said concerning the other point to which I directed attention—viz., the anatomy of the worm and the question of the genus to which it belongs.

On the scanty information existing concerning the anatomy of Filaria perstans.—To call this worm a Filaria means nothing. This name is admitted to cover a mere heterogeneous mixture of nematoids. In order to ascertain the genus to which a nematoid belongs we want descriptions of the adult worms containing, in addition to mere size and external form, particulars as to the nature of the mouth and pharynx, the relative length of the œsophagus and the *number of swellings*, if any, in its course, together with the situation of the anus, the character of the ovarian tubes, the situation of the vulva, the shape of the male spicules and accessory pieces, as well as any other details that may be recognisable. Particulars of this kind will be found concerning the 100 new species of free nematoids described in my "Monograph of the Anguillulidæ."[2] The figures of Tylenchus obtusus which I reproduced in my previous note were figures taken from adult worms, and yet Dr. Low says I have "fallen into a misconception respecting the anatomy of the adult and embryonic forms." The misconception is, however, really on his side in supposing that my figures were those of embryonic forms.

In attempting to put together the very scanty details given by Dr. Low and by Sir Patrick Manson concerning the anatomical characters of Filaria perstans the one fact that comes out clearly is that next to nothing is known concerning the internal anatomy either of the embryos or of the adult worms. The drawing of the embryo given by Manson in Quain's "Dictionary of Medicine," as well as the figures reproduced in the columns of THE LANCET by Dr. Low, show nothing more than the general shape and size of the worm. Manson says: "From time to time a minute, tongue like organ is rapidly protruded and withdrawn at the extremity of the cephalic end"; while Dr. Low says: "The cephalic armature as seen in fresh specimens consists of a non-serrated *prepuce*, difficult to make out, and the little fang first described by Manson." The word which I have put in italics is difficult to understand in this relation, and the "tongue-like organ" is now spoken of as a "fang," while nothing is said about its being retractile. There is no representation of it in the figures of either writer. It was Manson's description of this organ which made me think of the possibility of Filaria perstans being really a species of Tylenchus. My extensive acquaintance with free nematoids has only revealed three genera in which anything answering to a minute tongue-like organ that can be "rapidly protruded and withdrawn" exists—viz., Tylenchus, Aphelenchus, and Dorylaimus. And in the search which I have made through the works of Davaine, Eberth, de Man, Schneider, and other writers on nematoids, free and parasitic, nothing at all similar has been discovered in the species of other genera.

---

[1] Brit. Med. Jour., March 28th, 1903.

[2] Transactions of the Linnæan Society, vol. xxv., 1865.

In the paper published last year Dr. Low gave only rough outline drawings of the posterior extremity of the adult female and male specimens of Filaria perstans (the spicules of the latter not being represented), though in his communication in your columns there is what appears to be the reproduction of a photograph of the anterior extremity of an adult worm. It is difficult to say from this figure where the œsophagus ends, and whether the dark mass represents a portion of the ovary or the commencement of the intestine. No description is given. Speaking in his former paper of the adult worm he says: "The alimentary canal begins with a simple circular mouth and extends almost throughout the entire length of the worm." There is no description of the œsophagus and there is no mention of the "fang" or "tongue-like organ." It is absolutely contrary to all my experience with nematoids, either free or parasitic, that anatomical structures should exist in embryos and then disappear in adults. The "fang" or "tongue-like organ" therefore remains a mystery, and it must also be said that almost all internal anatomical details concerning the adult forms of Filaria perstans appear up to the present to remain unknown.[3] It is quite probable that the exertile "tongue-like organ" may not be comparable with the little exertile spear of Tylenchus or Aphelenchus. We must look for more definite information concerning it and also concerning the internal anatomy generally of the adult worms before any positive conclusion can be expressed as to the genus to which this worm belongs. Search for it in the external world also cannot be profitably carried out so long as such details are wanting.

Mode of infection.—In regard to the question of an intermediate host Dr. Low in his paper last year wrote as follows: "Analogy leads one to suppose that the embryo filariæ must be sucked out of the blood by some insect in which they may undergo the *metamorphosis*[4] necessary to enable them to become once more adult worms, and the peculiar distribution of the parasite and its association with dense tropical forests suggests some insect with a similar distribution." He admits that his rather extensive researches in this direction have hitherto yielded negative results; while Dr. Christy has expressed the opinion that available evidence does not favour the notion that mosquitoes are agents concerned with the causation and distribution of this filarial disease in Uganda. Manson also seems disposed to negative the supposition of the need in regard to this species of blood-worm for the existence of an intermediate host.[5] I am well aware that Dr. Low's argument from analogy is similar to, and probably in part based upon, views which were long ago expressed by Sir Patrick Manson in reference to another of the human blood-worms. It is, however, an argument which seems to me in this case to be more than usually fallacious. Of the common nematoids found in man—viz., Ascaris lumbricoides, Oxyuris vermicularis, Trichocephalus dispar, Ankylostomum duodenale, and Trichina spiralis—no intermediate host is known or supposed to exist and there is excellent reason for believing that ova or young embryos of each of these worms may be taken into the body directly with food or water and may go through all their developmental stages in the body of man.[6]

An "intermediate host" has, however, been predicated as necessary for two remaining nematoids—namely, the guinea-worm and the Filaria sanguinis hominis nocturna. In regard to the former worm, as I said in my previous communication,[7] all the most cogent evidence is opposed to this view; while in regard to the latter organism, notwithstanding all the painstaking researches of Sir Patrick Manson, nothing approaching proof exists.[8] Embryo guinea-worms, when brought into close relations with specimens of Cyclops, may be able to bore their way into the bodies of these organisms and live there for a time, and yet this may have nothing to do with the mode in which human beings contract guinea-worm disease. Similarly, when a mosquito sucks the blood of a patient swarming with embryo filariæ such embryos may live and advance slightly in development therein before the fourth or fifth day on which the mosquito dies and liberates them into the water, and yet no such temporary residence in the mosquito may be in the least necessary to enable these particular nematoids to undergo their customary development.[9] All embryo nematoids develop regularly by means of slight successive changes and at no period, when developing within their own proper environments, is there ever anything answering to what could be called a "metamorphosis," such as has been spoken of by Manson and by Low. At first the internal substance of an embryo seems simply granular and undifferentiated, then traces of the œsophagus appear followed by the rest of the alimentary canal, while later still the genital organs begin to appear. But the countless numbers of nematoids that may be found in all stages of development about algæ and other water plants, in almost all kinds of damp earth, as well as about the roots and lower leaves of many land plants, show that from the time they are born they are sufficiently "equipped for an independent life," and that it is wholly unnecessary for any of their early stages to be passed within the body of some intermediate host.

Sir Patrick Manson's arguments are, however, of this nature.

1. There is no evidence of growth or development of the embryos taking place in the blood. This, of course, must be freely granted. But supposing, as I am suggesting, that these organisms are facultative parasites which, getting into the human body with food or water, make their way from the intestinal canal into this or that site amidst the slow currents of the lymph stream, they may be perfectly capable of developing and producing swarms of young in such situations. This is what Sir Patrick Manson must suppose to happen to some of the partially developed embryos which have been liberated into water from the body of the mosquito. The subsequent passage of swarms of embryos into the blood stream may be regarded as a kind of accident and their perpetual involuntary movements in that situation may be sufficient to prevent their development. They have got into the wrong place and the majority of them are sacrificed. Some of them, it is true, may as a result of further accidents be thrown off in the urine and other excretions (even in tears, according to Lewis) and thus make their way into the outside world just as Manson supposes to be the case with those embryos that have been temporarily harboured in the body of the mosquito. In each case, therefore, they could only infect man as stray bodies existing in, and coming directly from, the outside world. It may well be asked, therefore, what is the good of assuming this temporary residence in the mosquito? Absolutely none, as I believe. There is abundant evidence to show that any such residence is wholly unnecessary to enable young nematoids to develop. Manson does not indeed postulate the necessity, as we have seen, for Filaria perstans, though he does postulate it for the nocturnal form of the blood worm. There would in any case be a prodigious waste of life, as is so often the case in nature. How small must be the percentage of the total number of embryos in the body of a patient that could be abstracted by mosquitoes; and then how small again, as Manson shows, is the percentage of such selected specimens which survive and become liberated into the water from the dead body of the mosquito.

2. Next we get a teleological argument. The fact that

---

[3] The vagina is said to "open externally some distance behind the head," that is, in a very unusual situation. The tube opening in that region in the figure of Tylenchus given by me is that of a large ventral gland and has nothing to do with the ovary.

[4] No italics in original.

[5] See the conclusion of his article on "Filaria Sanguinis Hominis" in Quain's Dictionary of Medicine.

[6] The case of Trichina spiralis is only an apparent exception to this rule.

[7] THE LANCET, Jan 30th, p 286.

[8] See his paper in the Journal of the Linnæan Society, 1878, vol. xiv. (Zool.), p. 304, and his more elaborate memoir in the Transactions of the Linnæan Society, second series, vol. ii. (Zool.), 1884, p. 367.

[9] Figs. 17–25 illustrating the memoir above cited are wholly unlike anything that is ever seen during the ordinary development of a nematoid and are rather suggestive of some morbid condition of the embryos.

the embryos of this particular parasite appear in the general blood stream only during the night is regarded as an adaptive provision enabling them to be swallowed by what are to be their temporary hosts, the mosquitoes. This is a kind of argument as to the cogency of which opinions are likely to differ much. Have we really to do with an essentially unimportant coexistence of phenomena or must we regard this coexistence as the result of some subtly wrought design, howsoever produced? Those who take the latter view would apparently have to suppose that these senseless [illegible] enabled to select [illegible] lood stream in [illegible] This surely is one of the many difficult problems still unsolved in reference to the life-history of these blood-worms. It would seem, however, that Sir Patrick Manson must be strongly influenced by this latter view. Otherwise he would scarcely believe a temporary residence in an intermediate host to be necessary in the case of Filaria sanguinis hominis nocturna and not for Filaria perstans.

Briefly, then, what I have been [illegible] this: (1) that we know next t[illegible] internal anatomy of Filaria persta[illegible] unable to say to what genus it belongs; (2) that it is practically an error to say that nematoids pass through one or more "metamorphoses," since they invariably (so far as is known) attain maturity by a process of steady and progressive development; (3) that nematoids stand in no need of being harboured by "intermediate hosts" but are from the time of their emergence from the egg or the parent perfectly capable of maintaining an independent existence; and (4) that, as a consequence, plants or vegetables in use as well as water may be the real sources through which nematoids obtain an entry into the human body, where they may be capable of developing as facultative parasites without having to pass through the body of any intermediate host.

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.[1]

BY EDMUND CAUTLEY, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN AND THE METROPOLITAN HOSPITAL.

THE case which I am recording presented many unusual features. It illustrates the difficulties sometimes found in making a diagnosis and in deciding on the appropriate treatment. It also shows that the affection may be easily overlooked and why such oversight occurs. That the affection is not uncommon is proved by the number of cases recorded in recent years and by the number which have come under the notice of individual observers. In a paper read before the Royal Medical and Chirurgical Society in November, 1898, although I only recorded 20 cases, including my own and those published by others, I ventured to state that in my opinion "the condition is not so rare as might be supposed" and that it is distinctly the cause of that symptomatic disease—marasmus—in some babies. In a joint paper with Mr. Clinton T. Dent on the affection and its treatment by pyloroplasty, read four years later before the same society, in December, 1902, it was mentioned that the total number of recorded cases exceeded 50. In other words, more than 30 fresh cases had been published in four years. Since then three more cases have come under my care and altogether I have seen ten cases in less than seven years. It is clear that the affection cannot be very rare and that the more the attention is attracted to it the more frequently it will be recognised. Such recognition is a most important matter, seeing that operative treatment has proved curative, while in the absence of such treatment the prognosis is almost hopeless.

The patient, who was born on June 22nd, 1903, was admitted to the Metropolitan Hospital on Sept. 22nd and died on Oct 3rd, aged 14 weeks. He was the first child of healthy parents and though supposed to have been born four or five weeks prematurely was said to have been a very large and fine baby. He was nursed for six weeks, then fed on Allen and Hanbury's No. 1 food, and after that on humanised milk up to August 11th, when he was brought to my [illegible]sence from town for my [illegible] weighed 6 pounds 11 [illegible] from vomiting and wasting. He was ordered a mixture of cow's milk and barley water. On August 18th he weighed the same, had vomited occasionally, and had had rather frequent stools. On August 25th he had gained one ounce. On the 28th he had lost an ounce, had developed thrush, and still vomited occasionally. On Sept. 1st he had lost two ounces, weighing 6 pounds 9 ounces. During the next week he gained seven ounces and a further six ounces in the following week, a noteworthy gain. On the 22nd I saw him for the first time and after careful examination admitted him as a case of congenital hypertrophic stenosis of the pylorus. He then weighed 6 pounds 14 ounces.

The important points in the history and course of the disease were as follows. According to the mother the vomiting began at the age of three weeks, had steadily persisted, and had become more frequent. It did not possess the usual characteristic that several meals might be kept down and then a large quantity of food brought up at once. The bowels had been costive and the stools small. The child had steadily wasted, except from Sept. 1st to Sept. 15th, when he gained 13 ounces. On physical examination it was noticed that he was very wasted, the fontanelle was depressed, the tongue was clean, and the breath was sweet. The abdomen presented a fulness in the epigastric region and the outline of the stomach was ill-defined. The stomach was hyper-resonant, a little dilated, and exhibited visible peristalsis passing in a wave from the fundus to the pylorus. A moveable lump of the size of a filbert could be felt in the region of the pylorus. He was put on a diet of equal parts of peptonised milk and water every two hours. On Sept. 23rd he vomited four times, immediately after food, up to 4.0 A.M. The amount vomited was small and consisted simply of the food. On the 24th there was no more vomiting and he took food well. The bowels were opened but the stools were small. There was no loss of weight. On the 25th the patient vomited twice during the night. He passed a large yellowish stool in the morning containing a few curds. On the 26th there was a loss of three ounces. He vomited once rather a large amount. He had two stools. On the 28th there was a gain of six ounces. There was no more vomiting. On the 29th four stools were passed during the night; they were green and contained some curds. On the 30th there was a loss of six ounces. He vomited once slightly. He passed seven stools containing little fæcal matter. The stools were green; there were no curds. On Oct. 1st he had only one stool and vomited once. On the 2nd there was a loss of seven ounces. He passed four stools during the day. He vomited once, about one and a half ounces, while the stomach was being examined. The pylorus was still felt. There was no increased dilatation of the stomach. On the 3rd he passed two stools and vomited once. He died from exhaustion, due to marasmus, in the evening. The temperature ranged between 97° and 99.6° F. throughout.

On post-mortem examination, 18 hours after death, nothing abnormal was found except the condition of the stomach and pylorus. On opening the abdomen the distended stomach was seen to occupy the left hypochondrium and the epigastrium down to the level of the umbilicus. The pylorus [illegible] cylindrical or sausage-shaped tumour about [illegible] one and a half ounces of dirty fluid, a little [illegible] and a moderate amount of gas. It was not found possible to squeeze any of the contents of the stomach through the pylorus although a probe could be passed through. On longitudinal section the pylorus showed the changes usually seen in this affection—[illegible] of the circular muscular [illegible] The [illegible] large [illegible] yellow fæces.

I wish to draw attention to the difficulties in making a diagnosis in this case. Previous experience had led me to form the opinion that as a rule the diagnosis is fairly obvious in a case under observation for a few days. In a typical instance we find progressive wasting, vomiting unaccompanied by nausea and characteristic of pyloric obstruction, absence of bile from the vomit, constipation, clean tongue, a sweet breath, a dilated stomach, visible peristalsis, and a palpable pylorus. Palpation of the pylorus is difficult on account of its deep position and one is apt to hesitate in stating with absolute confidence that it can be felt. I have felt it in the last five cases I have seen. Other tumours in this situation at an early age are very rare. An enlarged gland, if present, is not as definite and does not give rise to similar symptoms. Gastritis can generally be excluded on account of the clean tongue and sweet breath. In the present case the vomiting was certainly not characteristic. Although it had persisted for a long time and had become more frequent there was no history of a few meals being retained and then all brought up at once. During the 12 days the child was under observation in hospital the vomiting was not marked and had not the typical character. The bowels were stated by the mother to be costive. While under observation they acted fairly often and contained a considerable quantity of fæcal matter. On one occasion, eight days before death, a large, almost normal, stool was passed—conclusive evidence against very serious obstruction. Dilatation of the stomach was not very marked and did not increase while the child was under observation. Peristaltic movements in the stomach were noted on one occasion but were never present to the marked extent seen in some cases.

---

[1] A paper read before the Society for the Study of Disease in Children on Nov. 20th, 1903.

Another unusual feature was the extraordinary gain of weight which took place twice in the course of the illness, instead of the usual steady progressive loss. During one fortnight while attending as an out-patient the child gained 13 ounces. During two days, while an in-patient, he suddenly put on six ounces. If a child can gain weight like this there does not seem to be any urgent need for operation. Nor does there appear to be any reason why such improvement in nutrition should not continue. The affection was diagnosed from the wasting, the vomiting, the dilated stomach, and the palpable pylorus. On the absence of characteristic vomiting, on the presence of the considerable amount of fæcal matter in the stools, and on the two periods of gain in weight, I decided that the obstruction was only partial, that food could get through and at times in sufficient quantity for perfect nutrition, and that under such conditions the operation might be postponed. The child was very wasted and I hoped it might be possible to get him into a better state of nutrition or that he might be cured without operative interference. Even when he started to lose ground rapidly food was still passing through the pylorus, the vomiting was not marked, and the general indications for operation did not seem particularly urgent, looking at them from the point of view of relieving an obstruction.

Now note the peculiarity of the conditions found at the necropsy. The pylorus would not permit the passage of even fluid. No doubt this was due to post-mortem contraction. Note, too, that the intestines contained a considerable quantity of normal fæces. Clearly food had passed through the pylorus within a few hours of death and the degree of stenosis found at the necropsy is no measure of the obstruction present during life. The absence of characteristic vomiting during life is suggestive of the absence of spasm during life, the obstruction being due to a mere hypertrophy with secondary contracture of the hypertrophied muscle. The child's life might have been saved by operation. Four out of my last five cases have been operated on by Mr. Clinton Dent and life has been saved. In the present instance no operation was done and the child died. He died from marasmus, induced by starvation, from insufficient food passing through the pylorus. At the time he came under my care it is more than probable that he would have died from the marasmus in spite of surgical treatment, though the latter would have undoubtedly given him a better chance.

From this case it is clear that the affection can exist apart from typical symptoms, that an apparently mild case can induce severe wasting, and that operative treatment is indicated although food can pass through the pylorus. There is little doubt that the extent of the condition may vary in different cases and that both the diagnosis and the decision as to the necessity for operation may be matters of very great difficulty. I believe that mild cases may exist; that the symptoms may not be of much moment and may be limited to dyspepsia and occasional attacks of vomiting; and that such cases may terminate in later life from dilatation of the stomach and hypertrophic stenosis of the pylorus. Such cases have been recorded at five years (Hezekiah Beardsley), at six years (Sonnenburg), and at 11 years (Hansy). Probably hypertrophic stenosis of the pylorus in adults is simply due to a persistence and an exaggeration of a mild type of the affection in infancy.

Upper Brook-street, W.

RED LIGHT IN THE TREATMENT OF SMALL-POX.

(A FRAGMENTARY CONTRIBUTION.)

By J. T. C. NASH, M.D. Edin., D.P.H. Cantab.,
MEDICAL SUPERINTENDENT, BOROUGH OF SOUTHEND-ON-SEA SMALL-POX AND FEVER HOSPITALS; MEDICAL OFFICER OF HEALTH, SOUTHEND-ON-SEA.

WHILE awaiting results of the treatment of small-pox by light on a sufficiently large scale it is, I think, permissible for individual observers to record their results even when dealing with small numbers of cases, particularly if the cases have all occurred during the same epidemic and provided that some of the cases have been submitted to ordinary and others to red-light treatment. I further think that it is important to state in connexion with each case the apparent type of the disease, condition as to vaccination, and so on. Fully bearing in mind that the cases I have to record are too few in number to draw absolute conclusions from, I will content myself with just stating the facts. It is, however, important to mention that 25 of these cases occurred during one and the same epidemic in 1902.

In Table I. the last case of variola nigra may be eliminated as the fatal result was inevitable under any treatment. In all the rest suppuration occurred in the majority of the pocks. In the fatal unvaccinated cases the confluent eruption was very copious, even the abdomen in each instance being covered with pocks.

The Southend-on-Sea town council in February, 1902, on my advice, provided a new block with accommodation for eight additional beds. I had red-glass panes inserted in all the windows. Table II. gives the particulars of the cases admitted into this ward after its erection.

It will be noted that in each series there was one fatality from hæmorrhagic small-pox (variola nigra), death in each instance occurring within 48 hours of admission to hospital. As is well known, this type of small-pox is invariably fatal. Omitting these two cases (one in each series) as uninfluenced by treatment we have in the first series (Table I.), where the cases were treated in wards lighted by ordinary windows, 11 cases with three deaths, while in the latter series (Table II.), where the cases were treated in wards lighted with red-paned windows (at any rate until the pocks began to dessicate), 12 cases without a death. These are the bare facts as to the number of cases and the fatality in each series. But we must inquire more closely into the relative severity of the cases in each series before drawing any conclusions, bearing in mind, however, that the number of cases is too small to warrant absolute conclusions and that this paper is merely a fragmentary contribution towards the subject. Prior to making further remarks I will give in tabular form corresponding with Tables I. and II. the history of five cases of small-pox which have occurred in 1903 all of which have been treated in the "red-light" ward (see Table III.).

All the cases in Table III. were members of one family, vaccination of "contacts" after the first case being refused on religious grounds. Cases 2 and 3 were, however, still considerably protected by vaccination in infancy, but it is my impression that had these two persons been treated in a ward lighted by ordinary daylight some few of the pocks, at any rate, would probably have gone on to suppuration. In the unvaccinated cases, which were all well-marked typical cases with copious eruption, the vesicles became fuller and rounder towards the ninth day. A few were pricked with a needle and there exuded a thin semi-puriform fluid but no actual pus. Secondary fever was quite absent. Medicinal treatment was practically confined to acetozone, about six grains a day. Though I do not think that any of these cases would necessarily have been fatal if they had been treated in wards lighted with ordinary daylight I cannot but feel that the suppurative stage was considerably modified and rendered less severe and dangerous by the beneficial influence of the red rays, or rather by the exclusion of the other elements of light.

TABLE I.—GIVING PARTICULARS OF 12 CASES OF SMALL POX OCCURRING AT SOUTHEND-ON-SEA IN 1902 WHICH WERE TREATED WITH ORDINARY LIGHT.

Case.	Age.	Type of disease.	Vaccinated in infancy.	Revaccination.		Unvaccinated at the time of infection.	Suppuration stage modified by vaccination.
				Before infection.	After infection.		
1	21 years.	Copious eruption; semi-confluent; varioloid.	Yes.	—	—	—	Yes.
2	16 ,,	Very mild, discrete.	,,	—	Yes, but only unsuccessfully *after the eruption appeared.*	—	,,
3	59 ,,	Astacoid; confluent.	—	—	—	Yes.	No.
4	36 ,,	Mild, discrete.	Yes.	—	—	—	,,
5	36 ,,	,, ,,	,,	—	—	—	Yes.
6	21 ,,	,, ,,	,,	—	—	—	,,
7	41 ,,	Semi-confluent.	,,	—	—	—	,,
8	2 months.	—	Not before infection.	—	—	Yes, but vaccinated only one week before eruption, five days after infection.	,,
9	4 years.	Confluent.	—	—	—	Yes.	No.
10	11 ,,	,,	—	—	—	,,	,,
11	7 ,,	,,	—	—	—	,,	,,
12	18 ,,	Hæmorrhagic.	—	—	—	,,	—

Summary of the above Table.

	Vaccinated before infection in infancy only.	Revaccinated.	Unvaccinated at time of infection.	Total.
Cases	6	0	6	12
Deaths	0	0	4	4

One of the four deaths was from hæmorrhagic small pox. Of the six cases unvaccinated at the time of infection one was successfully vaccinated a week before the small pox eruption appeared, with the result that the infant escaped with a modified attack.

TABLE II.—GIVING PARTICULARS OF 13 CASES OF SMALL-POX TREATED WITH RED LIGHT DURING THE LATTER PART OF THE OUTBREAK (FROM APRIL TO JULY, 1902) AT SOUTHEND-ON-SEA.

Case.	Age (years).	Type of disease.	Vaccinated in infancy.	Revaccinated.		Unvaccinated at the time of infection.	Suppuration stage modified by red light.
				Before infection.	After infection.		
1	12	Semi-confluent; sequelæ axillary abscesses.	—	—	—	Yes.	Yes.
2	42	Semi-confluent.	No marks.	No.	No	?	,,
3	36	Semi-confluent on the face. This patient was early exposed to sunlight; the face took a long time to clear.	Yes; one poor mark.	,,	,,	—	,,
4	11	Semi confluent.	No.	,,	,,	Yes.	Yes, and by vaccination after onset.
5	35	Hæmorrhagic; fatal in 48 hours.	Yes.	,,	,,	No.	—
6	21	Discrete; in pustular stage when admitted.	Yes; good marks.	,,	,,	,,	—
7	2½	—	No.	,,	,,	Yes, but successfully vaccinated a week before eruption for the first time, 5 days after infection.	Modified by both vaccination and light.
8	36	Semi-confluent; epileptiform seizures.	Yes.	,,	,,	—	,,
9	37	Discrete.	Yes; good marks.	—	—	—	,,
10	56	Semi-confluent.	Yes, but no marks.	—	Vaccination did not take; no mark of vaccination at all.	—	,,
11	25	Very mild, discrete.	Yes; good marks.	—	—	—	,,
12	17	Confluent, severe.	No marks.	Certified, but no true vaccination cicatrix.	Yes; successfully after invasion.	—	,,
13	25	Confluent.	No.	No.	No.	Yes.	Yes.

Summary of the above Table.

	Vaccinated in infancy only.	Revaccinated.	Unvaccinated at time of infection.	Doubtful.	Total
Cases	6	2	4	1	13
Deaths...	1	0	0	0	1

The one death was from hæmorrhagic small-pox. It will be noted that the two cases under "Revaccinated" showed no evidence of any vaccination. They were stated to be vaccinated but really were unvaccinated in the proper sense of the term. Careful distinction must also be made between primary vaccination after infection and revaccination.

TABLE III.—GIVING PARTICULARS OF FIVE CASES OF SMALL-POX OCCURRING AT SOUTHEND-ON-SEA DURING MAY AND JUNE, 1903.

Case.	Age (years).	Type of disease.	Vaccinated in infancy.	Revaccination.		Unvaccinated at the time of infection.	Suppuration stage modified by red light.
				Before infection.	After infection.		
1	10	Confluent.	No.	No.	No.	Yes.	Yes.
2	35	Mild, discrete.	Yes; 4 marks.	"	"	—	Aborted.
3	33	" "	" 3 "	"	"	—	"
4	7	Confluent.	No.	"	"	Yes.	Yes.
5	3½	"	"	"	"	"	"

Summary of the above Table.

	Vaccinated in infancy only.	Revaccinated.	Unvaccinated at time of infection.	Total.
Cases	2	0	3	5
Deaths	0	0	0	0

I am aware that Dr. Schamberg[1] has recorded two unvaccinated cases of small-pox treated in a red room apparently complete in its appointments and that the result was such as to lead to the abandonment of this method of treatment. But I ask was it not rather premature to abandon altogether this form of treatment because the first two unvaccinated cases were apparently unmodified? The question of disfigurement, though of importance, is inconsiderable when compared with the question of recovery. If the mortality from small-pox, whether or not modified by vaccination, can be reduced at all by the use of red light is it not our obvious duty to give the matter the fullest possible trial? While fully recognising that prior vaccination undoubtedly plays the principal part in lessening the virulence of the disease in vaccinated persons, my experience hitherto justifies me in the belief that the red-light treatment is of distinct benefit. My record shows 18 cases treated with red light with only one death from hæmorrhagic small-pox (moribund on admission to hospital).

Seeing that in any particular epidemic the character of the prevailing form of small-pox, whether mild or severe, is a matter of great importance in determining both mortality and disfigurement, the question of the part played by red light is one which can be settled only by prolonged observation with careful records which must then be subjected to sound, calm, discriminate judgment: (1) by the observer himself; and (2) by others whose experience with variola and varioloid is sufficient to lend weight to such judgment. It is therefore clear that the present record is but a small item of evidence which weighs in favour of the red-light treatment of small-pox. I shall be content if this contribution is felt to be of any value, however small.

A disadvantage about a red-light ward is that the physical appearance of the small-pox eruption cannot be appreciated or demonstrated in the same manner as by ordinary daylight, but this disadvantage attaches only to the observer and not to the patient.

Southend-on-Sea.

ON THE DISTRIBUTION OF BACILLUS COLI IN NATURE.

PRELIMINARY NOTE.

BY J. W. H. EYRE, M.D. DURH., F.R.S. EDIN.

(*From the Bacteriological Laboratories, Guy's Hospital.*)

THE findings of the Commissioners, contained in the Fourth Report of the Royal Commission on Sewage Disposal (Pollution of Tidal Waters, with Special Reference to the Contamination of Shell-fish), which has recently appeared, although expressed in somewhat cautious language, are eminently suggestive. Perhaps the most important point raised is the paucity of our present knowledge as to the distribution of the bacillus coli in nature. For many years the presence of this organism in certain food-stuffs submitted to them for examination has been considered by some bacteriologists as proof positive of contamination by human excrement; and the fact that the bacillus coli leads a saprophytic existence in the intestinal canal of many mammals other than man appears to have had but little influence in modifying their views. In this connexion some of my own observations may be of interest.

For some years past, intermittently it is true, in the intervals of other work and as opportunity afforded, I have examined fæces obtained from various animals, with a view to the detection of the bacillus coli and allied forms of bacteria. In my earlier experiments the method I adopted was to emulsify small quantities of fæces in sterile broth, then to inoculate tubes of MacConkey's bile salt broth with the emulsion, to incubate anaerobically at 42° C. for 24 hours, and afterwards to pour gelatin plates from such of the tubes as exhibited growth accompanied by the production of an acid reaction and the formation of gas. For nearly two years now I have substituted plates of nutrose agar (prepared with some modification from the formula of the Drigalski and Conradi medium) for the gelatin plates, as this medium greatly facilitates the isolation of the bacillus coli from associated intestinal bacteria. Occasionally, too, I have smeared a few loopfuls of the suspension of fæces directly on to the nutrose agar plates—thereby cutting out the 24 hours' preliminary cultivation in bile salt broth.

In order to eliminate those bacteria allied to the bacillus coli, which are often loosely referred to as "coliform," I have refrained from classifying as bacilli coli any bacillus which did not present the following characters: short bacillus with rounded ends, feeble motility, not retaining the stain when treated by Gram's method; a non-sporing, non-liquefying, facultative anaerobe, giving characteristic colonies on gelatin, growing well on agar at 37° C.; producing an acid reaction when grown on milk, accompanied by clotting of the medium; producing indol in peptone water within three days; fermenting dextrose, lactose, maltose, saccharose,[1] galactose, mannite, glycerine, inulin, and dextrin, with production of acid and gas; reducing nitrates in nitrate broth to nitrites; and forming a moist, raised, fawn coloured to brown growth upon potato.

Like MacConkey I found that it was an easy matter to isolate the bacillus coli from the contents of the intestinal canal (obtained immediately after killing the animal) of the small rodents of the laboratory—the mouse, the rat, the guinea-pig, the rabbit, and also the cat and the dog. Examination of the fæces of larger animals—the sheep, the goat, the horse, and the cow—all likewise gave positive results. Specimens of the common fowl, the duck, the pigeon, and the sparrow, killed and examined immediately, also yielded abundant evidence of the existence of the bacillus coli in considerable numbers in the lower portion of the alimentary tract. In this connexion, too, it may be noted that Kern (1896) demonstrated the presence of bacilli coli in the intestinal tract of birds of prey. Recently, through the kindness of Dr. H. T. Bulstrode, I have had the opportunity of examining the bodies of two freshly killed sea-birds—a black-headed diver and a common gull—which were shot three miles from land (Boston Deeps, off Benington). The birds were carefully opened and some of the contents of the large intestines emulsified in sterile broth and plated on nutrose agar. After incubation the bacillus coli was found to be the predominant organism in the resulting growths. Still more recently, again thanks to Dr. Bulstrode, the inspector of the eastern sea fisheries (Mr. Donnison) sent me a batch of fish, freshly caught (off the Lincolnshire coast to the north of Marblethorpe) by means of a trawl net at a distance of about two miles from land and in a depth of four fathoms, the tide being half flood. The species represented were the sprat, the smelt, the mullet, the dab, the sole, the plaice, the John Dory, the dog-fish, and the skate. On receipt each fish was washed with sterile water, roughly dried with sterile cotton-wool, and tacked out on a piece of board. The skin of the ventral aspect over the situation of the alimentry tract was thoroughly seared with a red-hot cautery iron and the stomach and intestines were dissected out by means of sterile instruments. Some of the intestinal contents was then aspirated into Pasteur pipettes and thoroughly mixed with sterile broth. The mixture was then employed to establ [illegible] After incubation bacilli [illegible] from the sets of plate [illegible] endeavour was made to guard against the obvious objection to these observations by taking portions of the flesh from different parts of the body of each fish, dropping these pieces of tissue into tubes of bile salt broth and incubating at 37° C. With a few exceptions these cultivations remained sterile, the exceptions showing growth due to accidental contamination, the bacillus coli being absent from all.

---

[1] See also the Journal of the American Medical Association, vol. xli., No. 4.

[1] The original bacillus coli of Escherich, by the way, does not ferment saccharose.

Without going so far as to say that these results point to the presence of the bacillus coli as a normal inhabitant of the intestinal canal of fish in general—such a contention, of course, is neither warranted nor justified by these few observations—I would point to the necessity for further experiment in the directions which I have indicated before assuming that the presence of bacilli coli is synonymous with "sewage" contamination.

Guy's Hospital, S.E.

A CASE OF PAROXYSMAL LABYRINTHINE VERTIGO ASSOCIATED WITH SPECIAL OCULAR SYMPTOMS AND ALLEVIATED BY SETON.

BY T. WILSON PARRY, M.A., M.B., B.C. CANTAB.

THE patient was a Derbyshire man, aged 43 years when he first came under my care. He was of very temperate habits and before his first attack of vertigo which occurred now nearly four years ago he had never had any illness of any kind whatsoever. When he first came under my notice he was a general overseer on a gentleman's estate, had to superintend farm work, to attend himself to the horses, and also to do some office work. His father is said to have died at the age of 80 years from "pneumonia," while his mother died from the result of a second apoplectic seizure at the age of 74 years. I could discover no history of gout, syphilis, epilepsy, fits, migraine, or insanity. A paternal uncle suffered with "deafness." The patient's first attack occurred in March, 1900. He was writing at his desk in the office, when, without any warning whatever, he was suddenly seized with violent dizziness. So great was it, indeed, that he tumbled over on to some harness that was lying on the floor at his feet. He did not lose consciousness. The dizziness lasted about one and a half hours. He described the attack as commencing by his seeming to see everything go round and this in the reverse direction to that in which the hands of a clock turn. He made a great effort to master the illusion by fixing his eyes on some object but found that will power was incompetent to control the attack. He immediately felt sick and vomited. From this moment, firstly, a "singing" began in his right ear. Sometimes this was of a "sighing" nature, like "the fall of water in the distance," sometimes of a "buzzing" character, and again at other times of a "shrill" sound, "like an engine whistle going off." Secondly, sudden attacks of giddiness began to occur at certain times. These varied in character from the slightest vertiginous feelings, lasting only one or two seconds, to the most intense and violent paroxysms that threw him unawares on the ground, leaving him in a confused and dazed condition which lasted sometimes even several hours. Thirdly, he began to be troubled by a thing he had never had before—namely, "specks floating before his right eye." Sometimes these floated from side to side and at other times from above downwards. So realistic, indeed, did these "specks" (and often it was limited to one only) become that he used sometimes to imagine that a piece of soot was flying in the air in front of his face and he has found himself more than once sweeping his hand in front of his eyes to brush it aside. Fourthly, he began gradually to lose the sense of hearing in his right ear until he, in the space of 18 months, became stone deaf. This first attack naturally very much alarmed the man and he came to me with the tale that he thought there must be "something very seriously wrong with his liver." I examined him and found him to be a particularly well-made and well-nourished man, a total abstainer, and a moderate smoker only. I found no evidence of any organic lesion whatever and his urine, too, was free from both albumin and glucose. His knee-jerks were normal and there was no apparent arterial degeneration. I syringed away a small quantity of wax from his right ear and found the tympanic membrane quite normal. He was not entirely deaf but my voice appeared to him to be distant and muffled. I then directed my attention to the throat and nose. The throat was quite normal and I could find no evidence in the nose of ethmoidal disease or of any growth or morbid condition of the Schneiderian membrane to cause reflex irritation. Examination of the eyes elicited the following information: (1) both pupils were equal and reacted normally to light and to accommodation; (2) by the "ring" test I found that he used his right eye more than his left; (3) by rough tests he did not appear to be either myopic or hypermetropic to any extent; (4) there was no paralysis of any of the eye muscles; and (5) the discs were normal.

The treatment I adopted was free evacuation of the bowels by occasional powders of subchloride of mercury at night, followed by a dose of sulphate of magnesium the first thing the next morning. The chief drugs I employed for alleviating at the onset were quinine combined with bromides [illegible] I prescribed every four hours. [illegible] d vegetable bitter for stomachic purposes. For the first few days after the initial attack he had as many as three or four attacks in the day and then for three weeks he had none. At the end of this time he had two decidedly bad attacks. This brings me to the end of the month after his primary attack and from that time to August 6th, 1901, he was not under medical treatment, although, as he afterwards told me, he was conscious of the following symptoms during that period though they were not sufficiently aggressive to prevent him from undertaking his ordinary occupation. The symptoms referred to were: (1) singing in the right ear; (2) increasing deafness in the right ear; (3) occasional slight vertiginous attacks; (4) intermittent occurrence of muscæ volitantes flitting before the right eye; and (5) occasional frontal and occipital headache. During this quiescent interval I once met him in the street and he told me that although he had had no severe attack since he had last seen me he lived in apprehension of one occurring and asked my advice about his changing his employment as he was becoming afraid of dealing with, and managing, horses. I strongly advised him to give up his present occupation and to seek [illegible] did r [illegible] losing [illegible] chose, then, as I afterwards found out, the post of blacksmith for sharpening the men's picks in connexion with a quarry. On August 6th, 1901, that is to say, 17 months after his first attack, he was sharpening a pick on the forge when a sudden violent attack of vertigo came on and he was immediately obliged to lie flat on the ground. It took one and a half hours at least for the effects of this attack to pass off. Notwithstanding this he went to his work the next day and continued this till August 9th, when he had a slight attack which was succeeded on the next day by a particularly violent one. He was now obliged to relinquish work altogether as a series of attacks followed this last one which prevented him entirely from continuing his employment. The attacks were all on the same plan. There was no aura to usher them in. They began with dizziness, everything revolving in the direction aforementioned. During an attack he usually kept his eyes closed, not that this in the least diminished or retarded the sensation of vertigo, but, as he himself expressed it, it seemed "less confusing to him," as he did not then witness the appearance of things revolving. Then came a "coldness and sickness in his stomach" and he "sometimes felt quite faint." He then retched violently or even vomited, after which he broke out into a profuse clammy perspiration.

On Sept. 6th, 1901, Dr. R. H. Cole, who was staying with me at the time, kindly met me in consultation over him and we then elucidated the following definite points. 1. He was now stone deaf in the right ear, not being able even to hear a loudly-vibrating tuning-fork placed close to the auricle or, again, immediately upon the mastoid process. When both ears were closed with the fingers the sound was heard in the left ear. 2. He was repeatedly having paroxysmal vertiginous attacks which took him always suddenly, no warning whatsoever being given. Sometimes these were slight, while at other times they were so violent as to cause him to fall. The directions in which he had fallen were once forward, several times backwards, and again, at other times, as he himself described it, "all of a piece." 3. He was never without some kind of "singing" in his ears. On Sept. 14th a new symptom first made its appearance after an attack that occurred on that day. He had photophobia which remained persistently with him, always being worse after a fresh attack. Early in December I sent him to Mr. E. Collier Green of Derby to have my own diagnosis of the eyes being free from disease confirmed. The following was his report. "I examined the man —— at the infirmary to-day (Dec 6th). He has some very slight myopia in the right eye and some slight astigmatism in the left eye, otherwise his vision is perfect. His discs are normal. He needed glasses for reading which I have ordered. I did not discover any disease in either eye." I now quote short extracts from my case-book to give an outline of the further course of this disease.

On Dec. 13th the patient first began to wear glasses and as he had no attack for a fortnight (from Dec. 10th to 24th) he thought they were doing him good. On Christmas Eve he had an exceptionally bad "fit" and the retching after it was so severe that he told me he had brought up "about a tablespoonful of blood." This "fit" occurred just as he was intending resuming work again, as he had felt so much better. On Christmas Day he had another attack, but then no more for a fortnight. On Jan. 7th, 1902, he went to work until the 14th although he had slight attacks on the 9th, 10th, and 11th. He thought he had put on flesh during the last fortnight; before that he had lost considerably in weight. On the 14th he only saved himself from falling backwards by stretching out his arms and catching hold of the bellows' handle and tongs which were hanging up in the smithy shop. On the 18th I put him on ammonium chloride (12 grains to commence with) and lent him a pair of blue spectacles. On Feb. 1st he had had no attack since he had been wearing the blue spectacles. He found them to be a great relief from the glare of the snow and the lamp-light. He said that he could hear much better in his right ear. I again placed the tuning-fork on the right mastoid process and found that he could hear as well as when it was placed on the left one. He could also hear me speak with the affected ear in fairly low tones. He told me it had been getting gradually better during the past two months. He had three attacks with sickness on the 23rd; he had had none previously to this since Jan. 14th (six weeks). Photophobia was as bad as ever on the 23rd, 24th, and 25th but was better on the 26th. He had made up his mind to go to work on the 24th but was obliged to stay at home. Before these attacks the photophobia was much better but the attacks definitely increased it. He told me on the 26th that "his eyes had never been so that he could face the lamp-light properly since the very first attack." Before that time they were all right. I still kept him on ammonium chloride (15 grains). He could hear better. On March 2nd he had sickness and dizziness. He vomited his breakfast. His eyes were more photophobic after the attack. On the 9th he had a slight attack which left him with "smarting of the eyes, so that he could not go out to face the light and kept in his room with the blind only half drawn up." His hearing was improving.

With regard to the relationship of light to attacks, the patient felt that strong sunlight made his head "go light and a bit dizzy." He felt that a bright day was more predisposing to an attack than a dull one. After attacks the eyes were always more sensitive to light, sometimes more so than others. On March 28th he had had seven or eight attacks since he was last seen, and in the morning he had had one in bed. He said "it seemed as if the foot of the bed suddenly rose up." He had had no more attacks after getting up. The eyes ached a great deal more than usual. The ammonium chloride was continued. On April 6th he had had attacks innumerable lately. He never seemed to be free from them. His life seemed to be getting a perfect misery to him on account of them. I inserted a large seton in the nape of the neck. The first attack since the seton was put in occurred on April 10th. He tumbled down in a neighbour's garden, but the attack and the after-effects only lasted five minutes altogether. His eyes troubled him on the 11th by aching and photophobia. On April 16th no "bouts" had occurred since the last one mentioned. There were still aching of the eyes and photophobia. There was no conjunctivitis or any other special reason to account for this. He said that a certain "swimming in his head is brought on by his eyes." I left Derbyshire on April 25th, 1902. My successor (who modestly declines the publicity of print) kindly continued to advise me concerning the patient. On Sept. 17th, 1902, he wrote me the following: "—— had no fit after you saw him, resumed light work at the end of May and went back to his own work in the second week in June. On June 23rd I removed the seton. On July 26th he had a severe attack of vertigo and three days later he had two severe attacks with one of which he vomited. I introduced a fresh seton on July 30th and since then he has had no severe fit and latterly none at all; he has now resumed light work." This was very encouraging news and at this stage in the treatment we have a right to feel that the insertion of the seton did produce marked alleviation of the distressing symptoms, and if there had been no return of the attacks we might have considered that it had brought about a cure, but this unfortunately was not to be. On March 10th, 1903, I had word to say that after freedom from attacks for some time "he went to work again with the seton *in situ* and after a short spell had to give up owing to recurrence of the vertigo. These attacks were very severe for a time after this and I took out the seton and did not re-introduce it. About Christmas time he was again much freer from giddiness and I noticed that he was becoming much more deaf on the right side; he could not hear a watch tick until placed in contact with the ear. He again went on the club for a short time in February for giddiness but was soon at work again."

It will be noticed from the above that after each introduction of the seton the attacks of vertigo were either diminished or entirely checked so long as the patient remained away from his work, but that when he recommenced work the attacks returned also, from which I think one may deduce, as far as any single case may be considered conclusive, that when drugs fail to do good in the treatment of severe and distressing cases of Ménière's disease, one may get marked alleviation by giving the patient complete rest from his work and by inserting at the same time a good-sized seton in the nape of the neck. Boerhaave once wrote, "Vertigo est omnium morborum capitis levissimus et facillime curabilis."[1] I can only wish that this eminent physician had had an opportunity of confirming his hypothesis on this case. A list of the drugs employed throughout the first two years of treatment may be briefly summarised. Powder of subchloride of mercury, sulphate of magnesium, bismuth, and vegetable bitters for stomachic purposes and to exclude, by elimination, any doubtful diagnosis about the vertigo being "a stomacho læso" in origin; bromides (the potassium and ammonium salts) and hydrobromic acid given in conjunction with quinine and also without it; iodide of potassium given during a short course, but discontinued early as there was not the slightest apparent benefit; and ammonium chloride which seemed to do the most good of anything, or whether it was merely a case, while giving this drug a trial, of benefit being received *post hoc* and not *propter hoc* I am naturally a little diffident about dogmatising. Arsenic and salicylates I did not try, but apart from these I think that the above list includes all the important drugs of the British Pharmacopœia which are expected to do any practical good in Ménière's disease. The two points, therefore, that seem to me to be of special interest in this case are as follows: 1. The very unusual ocular symptoms occurring in a clearly defined case of Ménière's disease. We know that ocular vertigo of "erroneous projection" origin caused by paralysis of a single eye muscle may occur, the vertigo resulting being caused by

---

[1] Praelectiones de Morbis Nervorum, p. 475.

"confusion" of vision Mr Collier Green's careful examination of the eyes revealed no trace of muscular asthenopia Added to the easily recognisable auditory vertigo (vertigo ab aure læsa) of Ménière s disease was therefore superimposed an ocular vertigo of what one is obliged to call of "idiopathic" origin, which not only appeared to accelerate the onset of an attack of vertigo but definitely aggravated the ocular symptoms themselves at each successive vertiginous attack. 2 The distinct alleviation by the insertion of a seton in the nape of th
and—to the patient, I may
these sudden and violent attac
above mentioned had entirely failed to produce any adequate salutary effects It seems to me that surgeons at about the beginning of last century must have sometimes had recourse to this method of treatment in obstinate cases of Ménière s disease, although I have no doubt but that "bleeding would have been the first treatment to be adopted, and even this it seems to me, by unloading the intracranial sinuses would tend to relieve any hyperæmia there might be in the labyrinth and possibly procure excellent temporary results The very fact of this disease not having received a name till after 1861, when Ménière's classical case was published, is quite sufficient a reason for there being obscurity as to both diagnosis and treatment of this disease in times gone by Curiously enough, I have been through the titles of every published case of importance on this subject in the "Index Catalogue of the Surgeon General s Library, U S A" which brings one up in the literature of the subject to 1894 and again, I have looked over a number of the later volumes of the "Bibliographia Medica' and "Index Medicus," but can find not a single case whose title justifies the conclusion that the seton has been tried as a remedy in the treatment of Ménière's disease At any rate, whether it has been employed before or not I feel that as the results above enumerated have taken place in the present recorded case, which was, it will be admitted, of an exceptionally severe and persistent type, one has reasons for thinking that a slighter case would naturally yield much more beneficial results and, in any case, the treatment by seton in Ménière s disease is well worthy of a trial.

A CONTRIBUTION TOWARDS THE ETIOLOGY OF ALOPECIA AREATA

BY ARTHUR WHITFIELD, M D, M R C P LOND,
ASSISTANT PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT KING S COLLEGE HOSPITAL PHYSICIAN TO THE SKIN DEPARTMENT GREAT NORTHERN CENTRAL HOSPITAL

ALOPECIA areata, though merely a disfiguring disease rather than one causing pain or ill health, is sufficiently annoying to make sufferers from it extremely anxious to find an efficacious treatment At the same time, I think it will be admitted that the results of treatment directed against it are very often extremely unsatisfactory and any additional knowledge of its cause, though only applicable to a few cases, is of unquestionable value As is well known, the two main theories as to the causation of alopecia areata are the parasitic and the trophoneurotic, a great impulse having been given to the former by the publication of Sabouraud s careful work on seborrhœa oleosa and its bacteriology While admitting the presence of the organisms described by Sabouraud in every case where there is excessive formation of grease I have failed to find sufficient evidence that the bacilli are the cause of the symptoms Moreover, Sabouraud found himself forced to give up his contention that seborrhœa was the cause in all cases and to differentiate a special variety in children, which he called ophiasis and stated to be due to some cause other than invasion by the micro bacillus of seborrhœa More recently Jacquet has called attention to the frequency of disturbances of dentition—either abnormal eruption of the teeth or caries of existing teeth—in such cases and has credited the nerve irritation thus produced in patients whose general health is not quite up to the normal with the production of the bald areas. It is too soon to criticise this theory since, as far as my knowledge goes, his results and observations have not yet been carefully controlled by others but if it be correct it is probable that other causes of nerve irritation may determine the disease Some time ago I was struck, as I suppose many have been, by the frequency of headache and localised neuralgias in such cases and this led me to turn my attention to the sight as a possible cause of irritation The result was in some cases very striking, as the following will show

CASE 1—A woman consulted me for a large patch of alopecia areata on the vertex which had persisted for over a year in spite of careful local treatment On reading her prescriptions I found that she had used almost all the forms of local stimulants and antiseptics which are usually recommended for such cases Her health was not of the best and her occupation necessitated much close application near a lamp in a somewhat vitiated atmosphere Headache was a marked symptom and on inquiry I found that she had an error of refraction which had been corrected by a well known ophthalmic surgeon some five years before As her age was about 35 years I thought it possible that her glasses were no longer suitable and advised her to consult the ophthalmic surgeon again This she did and the glasses were altered, with the result that in six weeks' time the whole patch was thickly covered with new hair This patient suffered from marked seborrhœa oleosa and the micro bacillus was found by examination of the scales and by cultivation

CASE 2—Another woman came to me for a patch of alopecia areata over the left ear She had a great deal of work in selecting materials necessitating very close examination of the texture Headache again was a marked symptom but no seborrhœa oleosa was found. Her age was 38 years I had already treated her very unsuccessfully for some time when the possibility of eyestrain occurred to me and I got a friend of mine to examine her refraction His report was that she had well marked hypermetropia which had been latent and was becoming effective and that he had ordered her glasses Again the hair grew rapidly but this case was not quite so satisfactory as she came to me a year later with another patch and more headache Her health is still poor, as she has violent migraine, though she has lost the persistent headache from which she suffered before her vision was corrected

CASE 3—I was asked to see a student for a single patch of alopecia areata on the vertex His age was about 20 years and he already wore glasses for myopia, but the prescription for them had been given him a long time ago I sent him to the ophthalmic surgeon who found his glasses unsuitable and some curious changes in the fundus, so other glasses were prescribed The hair grew rapidly and remained healthy

CASE 4—While discussing this with another student recently he informed me that while reading hard for one of the examinations of the University of London he suffered severely from headache and developed alopecia areata After a couple of months his headache led him to have his eyes tested and his vision corrected, and the alopecia, which had so far resisted treatment disappeared in a very short time He did not connect the two and consequently his history is not very full of detail

Acting on the results of my earlier cases I had the vision tested in a large number of cases of children with alopecia areata The disease is very common in the earlier school years and I thought it quite possible that the strain of reading might determine it In one or two cases marked error was found but in by far the greater majority the eyes were evidently not the cause of the trouble and I wish it to be understood clearly that I do not claim to have discovered the cause of alopecia areata At the same time in this troublesome disease it appears that there is a certain percentage of cases in which the nervous irritation consequent on an undue effort to focus fine objects determines the onset of the symptoms in people whose health is not the most robust At all events, an inquiry into the correctness of the vision can do no harm

NOTE ON THE ACTION OF RADIUM AS AN ANALGESIC AND NERVE TONIC.[1]

BY DR. A. DARIER.

(*Translated for* THE LANCET.)

ON Oct. 6th, 1903, I described a case of cancer of the face which had been rendered painless by means of radium, an observation which has since been confirmed by other authorities. I have also noted the rapid and penetrating analgesic action of radium in certain cases of cyclitis and iridocyclitis and I have been able to reproduce these phenomena in other conditions with the same success for the last four months. It therefore appears certain that radium preparations of low intensity applied to a painful part are often capable of rapidly removing the pain.

The action of radium on the psycho-motor centres is still more remarkable. In two cases of convulsive neurosis in which the attacks occurred every day in one patient and three or four times a week in the other radium applications to the temples for two or three days were followed by cessation of the attacks. In a case of neurasthenic pseudo-ataxia radium brought about complete recovery in three days (probably by suggestion). In a case of acute facial paralysis of quite recent origin radium effected a cure in the course of the following day. Without attempting to explain these remarkable and novel effects, the observed instances of which are as yet but few, I think it right to make them known so that other observers may be induced to study this interesting question.

The activity of the radium preparations which I employed was tested in the laboratory of M. Curie and was found to vary from 10 to 7000 in terms of the accepted scale ("uranies"). For low activities I allowed the tubes containing the radium to act from two to four days and even for as long as 15 days, the pain sometimes reappearing shortly after the applications were stopped. With preparations having intensities from 1000 to 7000 the application was continued for two or three hours a day. In the above-mentioned case of facial paralysis I used high intensities of this degree. Preparations having a low intensity are moderate in price and recent experiments permit me to hope that similar therapeutic results may be obtained even with substances merely rendered radio-active by induction. If that proves to be so the cost of the treatment could be brought within the means of all patients.

Paris.

A CASE OF TRAUMATIC TETANUS TREATED WITH ANTITETANIC SERUM.

BY H. HOWARD MURPHY, M.D. CANTAB.

THE patient was a boy, 12 years of age, and usually healthy and strong. While at play on July 18th, 1903, he slipped off a plank and struck his left leg, causing a wound over the tubercle of the tibia; a triangular flap of skin with the apex downwards and the sides each about two inches long was torn upwards and bled freely. He was attended by a medical man who put in two sutures and applied an antiseptic dressing. The upper part of the wound healed but at the apex a little skin died. On July 27th the boy did not feel very well, his symptoms being malaise and headache. On the 28th he complained of stiffness of the jaws and neck and the masseters were noticed to be rather hard. Tetanus had therefore set in after less than ten days' incubation. On the 31st he was admitted to St. John's Hospital, Twickenham, with decided tetanus. The masseters were stiff, the mouth could not be opened beyond a quarter of an inch, there was slight risus sardonicus, and the muscles of the neck and back were somewhat stiff. The boy walked rather slowly and stiffly, his tongue was clean, and his bowels had been fairly opened. He was given a dose of calomel and a mixture containing bromide and chloral. A telegram was also sent to Messrs. Allen and Hanburys for a supply of antitetanic serum. The wound on the leg was healed, all but a very small spot healthily granulating. On August 1st there was more stiffness of the muscles, the limbs were somewhat affected, and the spasms of opisthotonos occasionally occurred. He was given a hypodermic dose of ten cubic centimetres of antitetanic serum in the right flank. The bowels were well opened by the calomel and the boy took liquid nourishment well. Towards the evening the spasms and pain were worse, so the mixture was given every two hours. His temperature was now 99° F. and his pulse rate was 100. On the 2nd it was noted that he had had a bad night, screaming frequently, with painful spasms and opisthotonos. A second injection of ten cubic centimetres of antitetanic serum was given and the medicine was continued every two hours. The temperature was 100° and the pulse-rate was 116 On the 3rd there were much less pain and spasm and the boy had short periods of sleep. The mixture was pushed till drowsiness was produced. A third injection of antitetanic serum was given. The temperature now went up to 102° and the pulse-rate to 120. On the 4th the boy was obviously better; he slept more, had less pain and spasm, could move his arms and legs a little, and could open his mouth slightly. His temperature was 100° and his pulse-rate was 105. He continued to improve slowly and steadily. The temperature and pulse fell to normal on the 6th and the movements of the muscles gradually improved. On the 9th he was given a dose of liquorice powder; this caused him griping pains and a return of spasm and stiffness for a few hours in the face, neck, and limbs. After this he slowly and steadily improved but had still some little stiffness and soreness of the limbs. After three weeks he was allowed to get up but could not walk because of stiffness and weakness of the legs and ankles, so he hobbled about with sticks. After another week he was discharged well.

In THE LANCET of Oct. 17th, 1903, a case was reported which seems to have been even more acute. My patient was no doubt much benefited by the antitetanic serum and even if the recovery is not to be ascribed entirely to it the result is an encouragement to use the serum in every case.

Twickenham.

RENAL HÆMATURIA PRODUCED BY TEREBENE.

BY ROBERT JOHN MACKEOWN, M.D. R.U.I.,
SURGEON, R.N.

THE attack now to be described was not the first of the kind which the patient had experienced, for at Wei-Hai-Wei in July, 1902, he suffered to a slight extent from the same symptoms after taking three minims of "terebene" out of the same bottle. He did not pay much attention to the matter and the effects passed away in a few days.

The history of the present attack was as follows. The patient, aged 34 years, got wet through at Shanghai on the night of April 27th, 1903. On the evening of the 28th he felt ill, took five minims of "terebene" on a piece of sugar at 8.30 P.M., and slept well. On the morning of the 30th he passed the usual amount of urine and towards the evening he noticed his urine turning red. Since the 30th the urine was red and it was worst on May 3rd. He came to see me on the morning of the 4th. His temperature was then 99 8° F. and his pulse-rate was 94. He complained of pain in the small of the back and the neck of the bladder, with frequent micturition. The urine after standing for five minutes was of a fairly bright colour throughout. The deposit at the bottom of the glass consisted of numerous tiny bright-red blood clots. It contained albumin and under the microscope numerous blood corpuscles were seen.

After standing for six hours the urine showed three layers in a glass six inches high. The lowest layer, one inch deep, consisted of a thick pinkish-white deposit containing numerous blood cells; the middle layer, four inches deep, consisted of a turbidity of a pinkish white colour, also containing numerous blood cells; the top layer, one inch thick, was of clear red-stained fluid, with very few blood cells. On the 5th his temperature was normal and he passed

---

[1] Read at the meeting of the French Academy of Medicine on Feb. 16th, 1904.

43 ounces of urine from 6 P.M. on the 4th to 6 P.M. on the 5th. The urine was now not nearly so bright as before; it contained less deposit and no clots.

From the 6th onwards he passed plenty of urine, the blood in which steadily diminished. He remained in bed and on low diet until the evening of the 9th when his temperature rose to 99·6° and his pulse-rate to 100. His face, trunk, and extremities were thickly covered with a most pronounced urticarial rash, the wheals being exceedingly large. The dermatitis caused œdema of the eyelids and face, so that it might at first sight have been taken for the onset of an acute attack of Bright's disease. I could not trace this attack to any error in diet; it lasted two days and then entirely disappeared. On the 13th there was no albumin in the urine. On the 15th the urine was alkaline, with no deposit, no phosphates on heating, and no albumin. The patient was then discharged to duty and as some anæmia was present an organic salt of quinine and iron was given On the 21st the urine was alkaline and of a bright amber colour; it deposited phosphates on heating but there was no albumin.

The treatment consisted of rest in bed and milk diet without solid food. Barley water was also given and ice was applied to the perineum.

It is difficult to say whether this was a case of renal hæmaturia or what is called "strangury" (hæmorrhage from the neck of the bladder). As the blood was uniformly mixed with the urine and as the urine was of a bright red colour and contained clots I think that the hæmorrhage was from the kidneys. The pain at the neck of the bladder might have been due to irritation from the urine. The drug which produced these effects was clear in colour with a taste of turpentine but scented and of a syrupy consistence. It was purchased at Brompton, near Chatham, and was labeled "pure terebene." The dose to be taken was not mentioned on the label. There was no return of the symptoms during at least the ensuing three months.

ST. MARY'S HOSPITAL.

A CASE OF SEPTICÆMIA WITH INTERESTING COMPLICATIONS.

(Under the care of Dr. W. B. CHEADLE.)

FOR the notes of the case we are indebted to Mr. F. Dering Nicholson, house physician.

A woman, aged 36 years, was admitted to St. Mary's Hospital on Dec 6th, 1903 under the care of Dr. Cheadle. Six weeks previously she had been confined, the labour being easy; she had had a good deal of pain in the abdomen afterwards, which was regarded as after-pains, and she got up on the tenth day. Bleeding from the uterus began and four days after became so severe that a medical man was called in who removed some clots, and three days later a piece of retained placenta which did not smell offensively. The hæmorrhage stopped, but about a week later thrombosis of the right femoral vein took place and the patient had a "white leg." She had several rigors since the removal of the retained secundines. Her past history showed that she had always been a healthy woman except for a cough of some months' duration; she had had eleven confinements, the labours being usually difficult and instrumental. Five of the births had been premature.

On admission she was seen to be very thin and anæmic; the nose was pinched, the extremities were cold, the temperature was subnormal (96·4° F.), and she looked extremely ill. The pulse was 124, small and of low tension but regular. There was no morbus cordis. Cough was frequent, loose, and harassing; the lungs showed signs of general bronchitis with congestion of the bases, but there were no pneumonic crepitations. Nothing abnormal was found in connexion with the alimentary system and a vaginal examination showed the uterus to be well contracted and freely moveable, there being no signs of old or recent inflammation in the surrounding tissues. The urine had a specific gravity of 1012, was acid in reaction, and contained no trace of albumin. She was given a mixture containing iron, digitalis, and magnesium sulphate three times a day. For the next fortnight she continued to be desperately ill; the pulse was about 120 and the temperature chart showed excursions from 97° to 103°, the variations occurring at all hours; rigors were frequent and severe, leaving her prostrate and bathed in sweat. The bases of the lungs showed no im-

she developed a severe pleurisy in the right axilla which did not go on to effusion; an icebag relieved the local distress but on the next morning it had to be discontinued as large petechial spots appeared at the points of contact which eventually ulcerated and slowly healed. Intense pain was felt in the hypochondrium but the gall-bladder could not be felt and there was no jaundice. In the evening she became much worse, was cyanosed, and had to be propped up in bed; she was too weak to cough and a low muttering delirium set in The pulse was 140. There were distinct signs of double basal pneumonia and larger quantities of alcohol with hypodermic injections of strychnine were resorted to. Examination of the blood revealed a staphylococcic infection and accordingly ten cubic centimetres of anti-staphylococcic serum were injected subcutaneously. On the next day she was better and continued to improve for four days; the lungs became freer of crepitations, the pleuritic rub disappeared, cough diminished, and she had no further rigors. The temperature gradually fell to 99°. A second and similar injection was made on the 28th, but her respirations rose to 40, the temperature to 102°, and she had another rigor. A third and last injection of ten cubic centimetres was given on Dec. 31st; no marked improvement followed and she had three rigors in the next two days. On Jan. 4th, 1904, she complained of aching pain in the right knee with some œdema of the leg and foot. The temperature rose to 103° and remained high for the next four days. Rapidly each extremity, and finally the neck, became implicated, the pain being intense and the tenderness so exquisite that she could not bear the lightest touch or movement There were no sign of phlebitis and no further œdema and the complication was diagnosed as influenzal neuritis. (N B.—There were several cases of influenza in the ward at the time.) This condition cleared up as rapidly as it appeared and proved, in fact, the crisis of the disease. The temperature fell on Jan. 7th to normal and has remained so ever since; all other symptoms rapidly disappeared, she began to sleep well, and evinced a hearty appetite. She is now up and about, is putting on flesh daily, and except for a little not unnatural weakness there is nothing to remind her of her severe illness.

Remarks by Mr. NICHOLSON.—One or two points are of especial interest: 1. Did she become infected from the retained secundines or a few days later on their removal? 2 The uterus and its surroundings showed no sign of recent inflammation. 3. The first serum injection was attended by marked improvement which was not the case with the two subsequent ones. 4. The onset of influenzal neuritis, interesting in itself, proved the woman's salvation and one can only suppose that the staphylococcus was no match for the bacillus of *Pfeiffer*.

CRUS HOSPITAL, NABLUS, PALESTINE

A CASE OF CLOSURE OF THE JAWS DUE TO CICATRICIAL BANDS.

(Under the care of Dr. J. CROPPER.)

A PEASANT boy, aged 12 years, was admitted to the Crus Hospital, Nablus, on Nov. 30th, 1903, with firm closure of the jaws of one year's duration due either to cancrum oris or ulcerative stomatitis of the right side of the mouth. There were three cicatricial bands, the foremost coming almost to the level of the canine tooth—i.e., to the angle of the mouth. So tightly were the teeth clenched that only the smallest fragments of food could be introduced through a gap on the left side caused by irregularity of the canine teeth. The finger could not be introduced between the teeth and the cheek and there was a most fœtid discharge from the mouth, the teeth being covered with tartar and pus from the ulceration of the cheek. An abortive attempt was made to cleanse the mouth with strong permanganate of potassium lotion.

Under chloroform the mouth was forcibly opened by carefully inserting a small gag on the left side, two teeth being dislodged during the process, all being more or less loose. When sufficiently opened to admit a knife the bands above mentioned were cautiously divided by Dr. David Katibah, then in temporary charge of the hospital; the cheek was also divided where it was adherent to the gums of the lower jaw. Hæmorrhage, which was free, was controlled by firm pressure from within and the mouth was cleansed as thoroughly as possible and the patient was sent to bed with the gag in his mouth and a cork between the teeth.

On subsequent occasions tartar was removed from the teeth and a variety of antiseptic lotions was used to bring the mouth into a tolerably healthy condition, the only really successful application being pure carbolic acid dissolved in the least possible quantity of glycerine, as is used for injection of hydrocele. This was swabbed on the ulcer every other day for a fortnight before the mouth was tolerably clean, after which time picric acid (saturated solution) was found to be sufficient. During this period and subsequently the patient, being old enough to appreciate the advantages to be derived from the treatment, luckily consented to keep the cork between his front teeth both by day and by night, removing it only for meals and syringing. The pressure of the cork on the already loosened teeth necessitated change in its position from time to time.

At the present time (Jan. 28th), two months from admission, the ulceration of the cheek is entirely healed, the part being covered with healthy mucous membrane. The cicatricial bands can still be seen and felt from the outside but are less prominent than before and the mouth can be opened to the extent of 2·3 centimetres (nearly one inch) between the incisors; the cork is now only worn occasionally at night but there seems to be no tendency to contraction.

Remarks by Dr. CROPPER.—The above case may possibly be an encouragement to some of the readers of THE LANCET who have had these very difficult cases under their care. Jacobson in "Operations of Surgery," remarks, "Division of bands inside the mouth is absolutely futile," but in the case related it is hard to see how effective treatment could have been otherwise carried out and in the event of future contraction the mouth is now in a sweet and healthy condition.

The good result in this case may be attributed first of all to the age of the patient and to his willingness to help in the treatment by day as well as by night, and not less to the assiduous care of the sister of the ward on whom devolved most of the treatment. In a younger patient such treatment would very likely be much more difficult, but on the other hand any operation such as that of Esmarch would have quite left untouched the fœtid condition of the mouth not seldom found in these cases; nor is it possible to avoid the conclusion that many, if not most, of the cases of relapse after division of cicatricial bands have been due to unhealed or half-healed ulcers in the mouth and to want of sufficient perseverance on the part of the patient or nurses.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Action of Adrenalin on the Metabolism of the Bird.—A Survey of the Recorded Cases of Hæmatoporphyrinuria not due to Sulphonal.

A MEETING of this society was held on March 1st, Dr. W. D. HALLIBURTON, Vice-President, being in the chair.

Dr. D. NOEL PATON read a preliminary communication on the Action of Adrenalin on the Metabolism of the Bird. He said that the object of the investigation was twofold. First, to determine if adrenalin produced a glycosuria in birds as it did in mammals. Herter maintained that it acted through the pancreas and as von Mering and Minkowski found that removal of the pancreas from ducks and pigeons was not followed by diabetes it was therefore evident that in these animals the organ did not play the direct part which it did in dogs in regulating the metabolism of sugar. Hence if Herter's view was correct it was to be expected that the injection of adrenalin in birds would not be followed by glycosuria. Secondly, to determine if adrenalin had an action on the proteid metabolism in birds similar to that which Dr. Paton had observed in mammals, since if such a disturbance was produced it might be expected to throw light upon the relationship of ammonia and urea to the production of uric acid. In mammals the ammonia nitrogen increased while the urea nitrogen was diminished. Was a similar decrease to be found in the uric acid in birds and, if so, was there increase of ammonia or urea nitrogen or of both? The following method had been employed. Geese were used and were prepared by making an artificial anus by cutting the gut above the cloaca and bringing it out on the abdominal surface at the posterior border of the sternum, while the opening into the cloaca was carefully closed by stitches. They survived the operation for many weeks and remained in good health. Throughout these experiments the preparation used was the adrenalin 1 in 1000 of Parke, Davis, and Co. The following results had been obtained. First it was found that the subcutaneous injection of large doses of adrenalin—about 0·6 cubic centimetre per kilogramme—caused a glycosuria in birds as it did in mammals. This observation seemed to militate against Herter's theory that the action of adrenalin was through the pancreas. Secondly, there was found a marked decrease in the proportion of uric acid nitrogen and other bodies precipitated by phosphowolframic acid. Of these, uric acid constituted about 90 per cent. The analyses of uric acid were not yet completed. Along with this there was a distinct decrease in the proportion of ammonia nitrogen and in one experiment a decrease in the urea nitrogen. It thus appeared that adrenalin influenced the metabolism in birds as it did that in mammals by interfering with the synthetic processes in the liver by which the characteristic end products, uric acid in the one case and urea in the other, were produced.

Dr. A. E. GARROD gave a survey of the recorded cases of Hæmatoporphyrinuria not due to Sulphonal. He pointed out that whereas hæmatoporphyrinuria was usually due to the taking of sulphonal there were a few cases on record in which similar urines, red or nearly black in tint and rich in hæmatoporphyrin, had been passed by patients who had never taken that drug. He referred briefly to 12 such cases, including one recorded by Baumstark in which there was some doubt as to the nature of the pigmentation. He drew a distinction between such cases and the very common ones in which there was merely an increased excretion of hæmatoporphyrin above the normal trace and in which the colour of the urine was not materially affected. It was shown that whereas hæmatoporphyrinuria due to sulphonal was hardly ever seen in males, of the non-sulphonal cases the majority occurred in males. Again, it was pointed out that in a large proportion of the cases not due to sulphonal the condition was of long standing and in some had persisted for many years, whereas in others it had occurred at intervals, and had in one instance simulated paroxysmal hæmoglobinuria. Except in Ranking and Pardington's cases the grave associated symptoms which accompanied hæmatoporphyrinuria due to sulphonal were wholly wanting and no specially evil prognostic significance appeared to be attached to the symptom. In the 12 cases discussed the patients suffered from a variety of maladies which had no obvious connexion with each other, but in three cases—viz., those recorded by Baumstark and by McCall Anderson, it was associated with a bullous eruption recurring each summer and leaving grave scarring of the face and hands. It was mentioned that the evidence forthcoming was opposed to the view that hæmatoporphyrinuria implied excessive hæmolysis and rather pointed to a perversion of hæmoglobin catabolism as its cause. However, although the study of the slight excesses of hæmatoporphyrin so often excreted in disease appeared to connect them with diffuse changes in the liver it could not yet be definitely stated that the profound disturbance of pigment metabolism which resulted in hæmatoporphyrinuria, with dark red urine, was wholly due to disease of that organ, although serious degenerative changes in the liver had been observed in some fatal cases in which the phenomenon was due to the taking of sulphonal.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 26th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Mr. F. J. STEWARD exhibited a case of Moveable Knee-joint three and a half years after operation for extensive tuberculous disease in a girl, aged five years. Primary healing was obtained and the limb had remained in a plaster-of-Paris splint for two years.

Dr. H. BATTY SHAW showed a mother and an infant daught [illegible] ity of the Hands and Fe [illegible] When the hands were at [illegible], flexed, the index fingers [illegible]; to be separated more t [illegible] gits. The inter-osseous spaces were wasted. Movements of flexion and extension were satisfactorily performed, but those of abduction and adduction of the digits were greatly reduced. There was also complete paralysis of the frontalis muscle. The child, aged two months, presented a similar deformity of the hands and feet. Radiograms of the mother's hand showed that beyond the slender character of the fourth metacarpal bones and the prominence at the base of the third the bones were normal.

Dr. BERTRAM L. ABRAHAMS showed a Sporadic Case of Friedreich's Disease in a boy, aged 13 years, the third of eight children, of whom the others were perfectly healthy. The illness began five years ago and the ataxy had rapidly increased during the past three years. There was slight lateral nystagmus. The pupils were widely dilated but re-acted briskly to light and accommodation. Romberg's sign was well marked. The speech was slow, nasal, slurred, and monotonous. There was considerable ataxy of the hands. Both knee-jerks were lost and the plantar reflexes were of the extensor type. Pes cavus was present on both sides and there was distinct dorsi-lumbar scoliosis. Treatment by Fraenkel's method was proposed.

Dr. J. P. PARKINSON exhibited an unusual case of Morbus Cordis in a girl, aged nine years, who since the age of seven had had repeated attacks of acute rheumatism. The cardiac impulse was best marked in the fourth inter-space just inside the nipple, and on admission to hospital she had epigastric pulsation and extension of the cardiac dulness to the right of the sternum. At the apex were double mitral murmurs and at the base were systolic and diastolic murmurs, heard best at the second left interspace. There was no abnormal arterial pulsation and the pulse was 70, small, regular, and compressible.—Dr. BATTY SHAW thought the proofs that the case was one of aortic regurgitation were incomplete. He could not help thinking that the condition was due to high tension in the pulmonary artery which gave rise to the murmur which had been described by Dr. Graham Steell.—Dr. ALEXANDER MORISON considered that the absence of a thrill negatived the diagnosis of pulmonary endocarditis and he was inclined to agree with Dr. Shaw that the condition was more functional in character than organic.—Dr. W. HALE WHITE believed that the presence of the systolic murmur indicated the existence of some endocarditis of the pulmonary valves.—The PRESIDENT observed that the murmur in question was heard very distinctly high up on the left side of the sternum. He would hesitate to pass an opinion without further examination.—Dr. PARKINSON, in reply, commented upon the great rarity of pulmonary endocarditis and considered that the condition was probably due to dilatation of the orifice from incompetence of a normal valve.

Dr. W. G. STONE showed a lad, aged 18 years, with Enlargement of the Bones of the Cranium, Jaw, and Thorax. The evidence was very strong that the lesions were syphilitic. The mother had had 12 children, five of whom had died under six months of age.

Mr. O. R KEYSER exhibited a male infant, aged 15 months, the subject of Achondroplasia with Spinal Curvature. The head was large and the fontanelles were widely open. The nasal bridge was depressed. There was marked disproportion between the length of the body and that of the limbs, the bones of which were only slightly curved. The fingers showed the typical appearance of the disease, the index and middle fingers curving to the radial, and the ring and little fingers to the ulnar, side. There was no lordosis nor was bony tenderness marked. There was a prominent antero-posterior curve in the dorsi-lumbar region. The lower rib were everted and the abdomen was prominent. The father was only 4 feet 8 inches in height.—The PRESIDENT inquired if anything unusual was noticed about the child at birth, and Mr. KEYSER replied that shortness of the limbs had been observed. He considered that there were several features in the case, especially the spinal curvature, which resembled those met with in ordinary rickets.

Mr. EDRED M. CORNER showed a case of Pyo-pneumothorax due to pulmonary tuberculosis in a man, aged 32 years, for the cure of which operations on the principle of Estländer's (thoracoplasty) were performed. Complete healing had taken place excepting for the formation of an aerial fistula through which air could be expired.—Mr. W. G. SPENCER referred to a case under his own care in which a bronchial fistula had resulted and which had remained stationary for three years.

Dr. WILLIAM HUNTER and Mr. STEPHEN PAGET showed a lad, aged 17 years, the subject of Progressive Myositis Ossificans. The disease began at the age of four years and since then had steadily advanced. Ten years ago he was seen by Sir James Paget and reported on by Mr. Stephen Paget at the time. There was a definite family history of rheumatic fever. The muscles chiefly affected were the pectoral, the latissimus dorsi, and the teres muscles, all of which were firm, rigid, and contracted, so that both the arms were fixed to the chest at the shoulder-blades. There was a deposit of bony growth around the angle of the left scapula. A considerable degree of scoliosis of the spine was present, with great wasting of the muscles of the back. Radiograms exhibited well-marked shadows at the attachment of the pectoralis major to the humerus.

Dr. O. GOULD MAY showed a female child, aged six years, with Multiple Exostoses on the bones of the limbs which had been first noticed six months before. There was no history of rheumatism, nor was there any pain.—Mr. W. H. BATTLE asked if there was a family history of a similar condition and if any effect had been produced upon the growth of the bones.

Mr. DONALD J. ARMOUR showed a man, aged 20 years, who had a Cyst arising in connexion with the organ of Giraldès, the origin of which was unknown. The swelling, which was at the upper end of the right testis, had been first noticed six months ago.

Mr. T. H OPENSHAW exhibited a female patient, aged 31 years, in whom he had treated Contractures of the Right Hip and Knee-joints by Elastic Traction. The condition had lasted for 15 years as a result of infantile paralysis. In July, 1903, she was placed in a Hessing's apparatus with elastic traction. Considerable improvement had resulted and power in walking was increased.

Mr. BATTLE showed a woman, aged 55 years, the subject of a large Femoral Hernia on the right side. The hernia had been present for 17 years; it was as wide as the patient's thigh and extended downwards as far as the upper margin of the patella. It contained intestine and the skin over it was somewhat eczematous in parts. He proposed to operate upon it when the general condition had improved.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Public Health Problems.—Modern Education.

A MEETING of this section was held on Feb. 12th.

Sir JOHN W. MOORE, the President of the section, delivered an inaugural address, taking for his subject Some Public Health Problems in Ireland. He instanced the dying out of opposition to the principle of compulsory notification of infectious disease as a substantial advance in preventive medicine. A second great advance had been the official recognition of diplomas in State medicine or public health. As to the prevention of tuberculosis, he considered that it was necessary to have compulsory notification of the disease, verification of the diagnosis by bacteriological examination, hospital treatment of the patients, and periodical disinfection of their homes. The President severely criticised the Poor-law system of Ireland, stigmatising the internal economy of the workhouses as a grave scandal and a national disgrace. In conclusion he dwelt upon the very unsatisfactory state of what may be called the "Home Medical Service"—namely, the Poor-law medical service—particularly in relation to the sanitary organisation of the country. In Dublin, as throughout Ireland, the dispensary medical officers acted as the medical officers of health for their respective districts and he contended that this hard-worked body of public servants should be properly recompensed for their services under the Public Health Acts. If the suggestions for the betterment of the health of the people made by the local medical officers were carried out intelligently and in a generous spirit the dawn of a brighter day for the Irish race would at last be near at hand.

Dr. R. B. McVittie read a paper on the Attitude of the Profession towards Modern Education from a Physical and Mental Standpoint. He pointed out that the great progress made in Denmark, Sweden, and Germany of late years was mainly due to the control exercised by the medical profession over primary education. He said that in the schools in Sweden and Denmark the children were only allowed to stay in one class for about 45 minutes; they then stood up and did exercises tending to correct the cramping from sitting down, after which they went out to the playground for some minutes. He considered that as man was a living and growing being only those who had made a life-study of physiology and biology were fit to be intrusted with this development, while, unfortunately, in the United Kingdom the only qualification which appeared necessary for what was called an educationist was a knowledge of some antiquated classic which, being purely abstract, tended more to arrest than to encourage orderly growth. As the nerve fibres from the surface to the pyramidal cell were myelinated first, all true education must be first concrete and abstract study should be discouraged as much as possible till the period of adolescence was fully completed, as too early a development of the psychic processes diverted the nerve energy from the control of tissue formation which was its natural function during the period of growth.—The President reminded Dr. McVittie that the Irish universities were moving towards improving education in the direction suggested by him; the Royal University had established a diploma in education and examined candidates for the qualification; Trinity College was moving on the same lines and lately a course of lectures was delivered there on the subject of education. He instanced the kindergarten as an example of the attention which was now given to the teaching of the concrete as distinguished from the abstract.

Harveian Society of London.—A clinical meeting of this society was held at St. Mary's Hospital on Feb 25th, Dr. C. Theodore Williams, the President, being in the chair.—Dr. D. B. Lees showed two cases, the first a case of Aphasia with Anomalous Symptoms and the second a case illustrating the use of Large Doses of Sodium Salicylate. This patient had taken at irregular periods so much as 400 grains per diem in combination with bicarbonate of potassium and if the drug was discontinued her rheumatic symptoms immediately recurred. He referred to the stimulating effect of the drug when given in large doses in contradistinction to the depressing action so often seen when small amounts were taken and strongly advocated heroic doses even in the case of children. He deprecated the fear which caused the withholding of the drug when ear symptoms developed and advised pushing it at this period, as when the quantity given was large enough no ear or other untoward symptoms appeared. This case exhibited well the great tolerance patients had, or soon acquired, for sodium salicylate. —Dr. W. Hill inquired as to the cause of absence of tinnitus when administering these large doses of sodium salicylate; was it due to the combination with the bicarbonate of potassium?—Dr. Lees said that he did not know the explanation of the varying results as regards tinnitus.—Dr. Sidney P. Phillips showed a case of Osteo arthritis of the Spine in which there were thickening, pain, tenderness, partial fixation by spasm, and rigidity over the upper four dorsal spines. The head was slightly flexed to the left and rotated at an angle to the vertebræ. The presence of brawny induration suggested caries or new growth but there was osteo arthritis in other joints. The deltoid, pectorals, and triceps on the one side were wasted and there was deformity of the fingers with glossy skin and tingling of the same hand, suggesting pressure on the nerves in the inter-vertebral foramina. Dr. Phillips thought that these cases were much more common than was usually assumed.—Mr. J. P. Lockhart Mummery considered the case to be one of those called spondylitis deformans and he had heard of a case where four brothers in one family all suffered from the disease, suggesting heredity. As a rule, it was uncommon to find other joints affected in this condition.—Dr. Phillips did not consider it to be one of the ordinary type referred to, as it seemed to him to be a case of pure osteo-arthritis of the spinal articulations.—Dr. H. A. Caley showed a case of Raynaud's Disease with Splenomegaly. The patient, a woman, aged 45 years, had suffered from coldness and lividity, chiefly affecting the left thumb and index finger, for some months, and it was noteworthy that there were intense pain and cutaneous hyperæsthesia resembling the condition met with in erythromelalgia. The enlargement of the spleen had apparently come on acutely during a severe illness some weeks before. There were no characteristic blood change and no history of malaria but evidence of perisplenitis. The history suggested that the primary lesion was vascular, thrombosis, but there was probably actual hypertrophy.—Dr. E. Cautley asked Dr. Caley whether the splenic notch was in a normal condition—that was, was the growth symmetrical? He had seen a case with twisting of the pedicle in which the organ enlarged, then subsided, but left some permanent increase in size; this case might be of the same nature.—Dr. Caley thought the axis was normal and the notch proportionately normal, but the patient was too tender to examine carefully. Against twisting of the pedicle was the fact that symptoms came on when the patient was at rest.—Dr. Theodore Williams commented on the case.—Mr. A. Q. Silcock showed a woman, aged 30 years, who had been the subject of a Dermoid Cyst of the right side of the chest. She was admitted to St. Mary's Hospital under the care of Dr. Lees in February, 1903, presumably suffering from empyema which was opened and found to contain a large quantity of caseating sebaceous material mixed with pus. Subsequent examination proved the empyema to be a suppurating dermoid cyst. Portions of the cyst wall were removed at intervals, the patient being too weak to stand prolonged operations. As a result the cavity became smaller and suppuration diminished. Finally, the whole of the remaining cyst wall was dissected away from the lung above, from the diaphragm below, and from the pericardium internally, to which it was firmly adherent, a large opening being made in the lateral wall of the thorax to allow of the introduction of the hand. After prolonged convalescence the cavity closed with the exception of a small sinus which still remained. Mr. Silcock remarked upon the infrequency of the affection and upon the fact that many of the reported cases had been mistaken for empyema. The cyst was of about the size of a polo ball or larger. He had as yet been unable to find a case in which a cyst of this size had been extirpated and pointed out the difficulties of so doing, especially in separating it from the pericardium.—Dr. Lees considered the case unique. When admitted he thought it to be a pleuritis. There was slight pain in the side, with cough; the heart was pushed far into the left axilla—a point against pleurisy but which might be present in hydatid of the lung or the liver. The case was difficult to examine. The house surgeon opened the pleura and sebum appeared. Dr. Lees remarked upon the wisdom of surgeons performing extensive operations in segments rather than trying to do too much at once. This case was so treated and was a veritable triumph of surgery.—Dr. Theodore Williams thought that the lung bore a great deal of knocking about but the heart seemed even more tolerant as shown by this case and the vagaries of foreign bodies lodged in the heart.—Dr. R. Boxall referred to an interesting case of the heart being dislocated from the pericardium through a congenital opening into the left pleura in a woman a few days after delivery.—Mr. W. H. Clayton-Greene showed a case of Hernia Cerebri following a compound depressed fracture of the skull. The patient, a girl, aged ten years, fell out of a window into an area and was admitted to St. Mary's Hospital under the care of Mr. Silcock. A wound in the frontal region was opened, two depressed fragments of bone were removed, the wound was irrigated, and a dressing was applied. Three days later the wound was found to be suppurating and the brain was protruding. The stitches were removed and the wound was thoroughly opened up and irrigated with saline solution. In spite of local treatment the brain protrusion increased. About a month after admission a mass of hernia cerebri of the size of an orange was excised; free hæmorrhage resulted which adrenalin failed to check. The patient suffered great pain for 24 hours after the operation and on the next morning showed a slight amount of facial paralysis. The hernia gradually re-formed and surpassed its original size. A second removal by means of an electric snare was followed by little bleeding and no shock. Extensive œdema of the eyelid, the face, and the neck appeared but gradually subsided Three points of interest were remarked upon 1 The hernia consisted largely of brain matter, not granulation tissue 2 All treatment short of removing the protrusion was ineffectual. 3 In spite of abscission of a large portion of the frontal lobe there was no loss of intelligence or moral perversion so far as could be judged The facial paralysis was rapidly improving —Mr P L Daniel showed a *young woman, 24 years of age, who* immediately after delivery of a second child 19 months previously was seized with small pox Seven weeks later when she returned from hospital she noticed in the right side at the margin of the thorax a small "knot" This had gradually increased in superficial extent and now presented as an oval patch three by two and a half inches, of faint red colour, paler in the centre, slightly raised, doughy in consistence, with definite softening in the centre where it was slightly tender, but without loss of surface epithelium The right thorax was slightly deformed She had slight scoliosis Examination of the chest on this side elicited dulness, loss of breath sounds, and impaired vocal fremitus She had slight and obstinate cough and brought up yellowish phlegm A blood count showed 16 000 leucocytes per cubic millimetre Mr Daniel considered the case to be one of cutaneous actinomycosis associated with visceral involvement, a condition which in recent years was shown to be not uncommon and was considered to be syphilitic because it cleared up under potassium iodide —Mr F Jaffrey referred to two cases of a somewhat similar nature which did not break down but cleared up *under potassium iodide One patient received as* much as 200 grains per diem of the drug, the other from 40 to 50 grains He considered the administration of from one to two pints of water to be essential for success in giving large doses of iodide One patient had actinomycosis of the liver and the other of the cæcum —The President agreed with the condition of the chest as described but could not agree that the condition of the skin was typical of actinomycosis —Dr. E G Graham Little showed an interesting case of Lupus associated with Lichen Scrofulosorum An injection of tuberculin (No 1) resulted in a typical reaction, in which the lichen scrofulosorum participated, becoming vividly red —Dr Nicholson (for Dr W B Cheadle) showed a case of Supposed Primary Malignant Disease of the Liver, with microscopical specimens The patient, aged 35 years, had a very large liver which was punctured by a needle and at the point of exploration a secondary deposit occurred in the skin, which on examination proved to be a typical columnar celled car*cinoma with well marked alveoli* No primary focus was found in the intestine but the patient had melæna He also showed a patient, aged 35 years, suffering from Syphilitic Endarteritis Obliterans who had had syphilis 13 years previously Great improvement took place under iodide of potassium

EPIDEMIOLOGICAL SOCIETY —At a meeting of this society held on Feb 19th, Dr B A Whitelegge the President, being in the chair, Dr Myer Coplans, late civil surgeon attached to the Royal Army Medical Corps in South Africa, read a paper on the Etiology of Scurvy based on his observations in South Africa towards the close of the Boer war *when the entire population, military and civil, British, Dutch, and native, was maintained at the cost of the Govern*ment on rations of good and known quality, uniform in each class, the chief of these being (1) burghers in concentration camps, (2) European soldiers, and (3) natives attached (*a*) to the British army and (*b*) to the civilian repatriation department Each concentration camp contained about 5000 persons, 48 per cent. being children under 12 years of age, and among adults the women were to the men as 3 to 1 Inclosed by barbed wire the camps, though open and airy, were securely isolated The conditions being identical the varying incidence of scurvy was remarkable Between March, 1901 and January, 1903, with no cases at Standerton or Volksrust, there were 100 Europeans and one native attacked Among the soldiers at Standerton and the 22 000 European patients admitted to the hospital there was but one, among the natives in the service of the troops there were attacked 32 per cent of 400 muleteers, 22 per cent of those attached to the Hussars and the Royal Artillery, 87 per cent of the scavengers *engaged in removing carcasses of* animals, 17 per cent of the porters, and about 50 per cent of the muleteers in the employ of the repatriation department The *heaviest* incidence of scurvy was after the close of the war and when all *restrictions on food* had been removed *In fact,* it had no relation whatever to the food but was almost everywhere directly in proportion to the neglect of cleanliness, of which the natives had not the most rudimentary notions, especially as regards the hygiene of the mouth Even the outbreak among the burghers at Middleburg followed overcrowding and neglect of sanitation As to treatment, *the food, though mostly* preserved and tinned, was good but many refused the harsh, sour lime juice Dietetic treatment was very successful rapidly so if accompanied by mechanical cleaning of the teeth and gums with continued use of antiseptic washes, though more slowly without.—Dr A E Wright considered it a great mistake on the part of Dr Coplans to confine his study to South Africa, for filthy habits *were not peculiar to the Kaffirs* and were unaccompanied by scurvy which he had seen in the nurseries of the rich and in a lady in a nursing home Would Dr Coplans assert that the food was all good or that all partook of it? Scurvy was essentially an acid intoxication, a reduction in the alkalinity of the blood which could be observed long before the grosser manifestations alike in the adult and infantile forms A large proportion of the troops returning from South Africa were scorbutic in the latent stage All that was essential in treatment was to render the blood as alkaline as possible Meat and cereals were deficient in alkali and in salting meat lost what little it had Citric acid was useless Fresh vegetables and potatoes with fresh fruits were all useful but the specific was lactate of *sodium —Lieutenant Colonel* R H Firth R.A M C, noticed the low values of the dietaries as given by Dr Coplans, few exceeding 2000 kilocalories, or barely enough for the body work The ash of tinned milk was often acid instead of alkaline In one expedition he had had to condemn 30 per cent and a large proportion of our troops on their return from our "little wars" were more or less scorbutic —Colonel J Lane Notter, R A M C, had left South Africa before Dr Coplans's statistics commenced but he could fully bear out his description of the filthy habits of the Kaffirs who, though supplied with good food, preferred putrid meat or the *entrails of dead animals*—Mr K W Goadby had not seen any cases of scurvy at the *Dreadnought* Hospital but had met with several of pyorrhœa alveolaris, a disease endemic and occasionally epidemic in West and Central Africa, the Transkei, Philippines, and other places, in which the condition of the gums and their rapid recovery under antiseptic measures resembled that in scurvy —Dr H T Bulstrode referred to a paper read in the society 20 years ago by Sir W Smart, who quoted from Lind a passage showing that that great naval surgeon had already 150 years ago rejected the belief in the specific action of lime juice —Dr E F Willoughby was surprised that no one had made any reference to the theory of Dr Tonk of Christiania which had been accepted *implicitly* by all medical authorities in the Scandinavian marine While fully satisfied that the essential cause pathologically was as Dr Wright had *shown, an* excess of acid or want of alkalinity of the blood they could not ignore the practical etiology or the preventable conditions under which this pathological phenomenon was brought about and Dr Tonk's view that scurvy was no more or less than a chronic ptomaine poisoning was the only one that explained or agreed with all the phenomena, positive and negative of its history The field of the late war was too wide for accurate observations but in the last six or eight Polar expeditions they had a series of carefully conducted experiments leading to the conclusions that without a single exception (1) a diet of fresh, even raw meat, *without* any fr [illegible] with hardship, dirt [illegible] entirely of tinned, [illegible] highest quality, but with no fresh food, animal or vegetable, did not produce any of the symptoms of scurvy, while scurvy appeared when along with potatoes, &c., and daily doses of lime juice, the bulk of the food consisted of ordinary salt beef or pork Until the recent Antarctic expedition no Polar expedition from that of Nordenskjold in the *Vega* had been attacked by scurvy except those of Jackson's men who *remained on board the ship, where they* had lime juice, *potatoes, &c, but refused the coarse bears'* flesh on which alone the exploring party subsisted, they often remarked the "high gamy" flavour of their meat and all were attacked with scurvy, two indeed dying The Lapps of Finland bartered for farinacea &c, but ate their fish putrid by preference and suffered much from scurvy.

—Dr. Kenwood, Lieutenant-Colonel A. M. Davies, R.A.M.C., Dr. Newton Pitt, and others having spoken, Dr. Coplans replied, chiefly dealing with Dr. Wright's statements. The disease did not appear while the natives had only their own mouldy mealies but when supplied with sound South American maize and more wholesome Government stores than they could eat. It required, as Dr. Wright maintained, months for its development, for the members of the corps that suffered most were recruited in their own homes in October and the corps was dissolved in December, the disease breaking out soon after arrival in camp and recovery followed rapidly on purely local treatment in the way of buccal antisepsis without any attempt to influence the blood.

Chelsea Clinical Society.—A meeting of this society was held on Feb. 16th, Dr. T. Vincent Dickinson, the President, being in the chair.—Mr. L. A. Bidwell read a paper on Some Cases of Subacute Pancreatitis and after briefly referring to the etiology and symptoms of acute hæmorrhagic pancreatitis he described four cases of a subacute form of the disease in which he had operated. He was inclined to think that these subacute cases were pathologically the same as the acute cases and that the difference depended on a less virulent type of micro-organism or on the greater resisting power of the patient. The diagnosis of subacute pancreatic disease was very difficult but he pointed out that the following symptoms should lead the surgeon to suspect its nature: the intensely acute character of the pain situated above the umbilicus in a patient who had had a history of gastric or gastro-duodenal catarrh, vomiting which was often very profuse, great collapse, and irregular temperature, and later the occurrence of resistance, dulness, and a swelling in the epigastric region. This was accompanied by extreme emaciation. In some cases glycosuria might be present and in others free fat might be found in the motions, which also might be colourless although no symptoms of obstructive jaundice were present. In his first patient the diagnosis made was that of empyema of the gall-bladder and it was not until the abdomen had been opened and the gall duct found to be healthy that the true nature of the case was recognised. A large collection of turbid, dirty-brown fluid was present in the lesser peritoneal cavity and the pancreas was found to be much enlarged. The patient recovered from the operation and his wound healed but he died some six weeks later with symptoms suggesting the formation of a secondary abscess. In another case the symptoms rather suggested that the kidney was the seat of the trouble and this was explored without any benefit. At the necropsy an abscess involving the tail of the pancreas was found. In the last case there was remarkable absence of the characteristic pain but a tumour appeared above, and to the left of, the umbilicus and the patient was emaciated. The tumour was explored and found to be an abscess in the tail of the pancreas. This was drained and the patient made a perfect recovery. It was noted that neither of these cases of abscess of the tail of the pancreas suffered from glycosuria. He was sorry to have to admit that none of these cases had been diagnosed before operation but he thought that the conditions found afforded another argument in favour of abdominal exploration in obscure cases.—Dr. R. T. Hewlett read a paper on Pyrexia in the Course of Late Syphilides. He pointed out that while fever was common in the secondary stage of syphilis it was not frequent in the tertiary stage because the inflammation was of such a chronic nature. In periostitis a slight degree of fever was often observed but in visceral lesions it was usually absent. Dr. Hewlett then detailed the histories of four cases of tertiary syphilides in which fever was present. The first presented no difficulty, being a case of syphilitic periostitis of the calvarium. The second was a case of syphilitic arthritis of the knee presenting a remarkable temperature curve, the temperature having a diurnal range of from about 99° F. in the morning to 101–104° in the afternoon between 2 and 6 P.M. On being put on iodide the temperature fell abruptly to normal and continued so. The third case was also one of syphilitic arthritis affecting the shoulder and elbow, with a temperature ranging between 99° and 100°. At first the case looked like one of subacute osteo-arthritis but the effect of iodide and mercury was instantaneous. The fourth case was that of a thin, delicate man, with pleuritic-like pain and rub at the right base, some cough and expectoration, slight signs of mischief at the right apex, and a temperature ranging usually between 99° and 100° but occasionally rising to 101°. The case was regarded as tuberculous but the sputum was repeatedly searched for tubercle bacilli without result. One day the liver was noticed to be enlarged and on iodide being given the temperature fell abruptly to normal and the symptoms disappeared. The case was evidently one of syphilitic perihepatitis.—Dr. C. O. Hawthorne gave an interesting lantern demonstration entitled "The Field of Vision in Health and Disease."

Bradford Medico-Chirurgical Society.—A meeting of this society was held on Feb. 17th, Dr. Henry Angus, the President, being in the chair.—Mr. C. F. M. Althorp read notes on a case of Sarcoma of the Jaw upon which he had successfully operated and showed specimens.—Dr. H. J. Campbell read a paper on the Causation of Cancer. He enumerated a number of the various theories which have been propounded on the subject and among the conditions which have been assigned as causes of the disease he directed attention to: (1) embryonic cell rests taking on growth and forming tumours; (2) irritation by vegetable micro-organisms; (3) irritation by animal micro-organisms analogous to coccidia in rabbits; (4) the association of yeast growths with tumours; and (5) the displacement of portions of epithelium which subsequently take on growth. He also discussed (1) various dietetic theories; (2) the suggestions of Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker that existing cells might take on the function of germinal cells and form tumours; and (3) the work of Dr. E. F. Bashford and Dr. J. A. Murray concerning the formation of new growths in different animals. The question why the cells of any part should take on reversion to a germinal type was considered. It was suggested that chronic irritation might often determine the site of a tumour, and also that the involution going on in certain organs (such as the breast and uterus) at the cancer age might have some influence in this direction.—The President suggested that as cancer usually came on at the end of sexual life, the cells of other parts of the body might seem to attempt to take on the function of sexual cells.—Dr. A. C. F. Rabagliati said that in his opinion the question of the division of cells was of little practical interest; cancer was a disorder due to the ingestion of excessive amounts of nutrient material. It was useless to discuss the question of "cancer houses" unless the habits of the people who lived in the houses were also studied.—Dr. F. W. Eurich said that it seemed to him that all the circumstances attending the growth of a malignant tumour tended to point to a parasitic origin. He remarked that animals in menageries, although they were certainly not overfed, often developed malignant tumours.

Therapeutical Society.—A meeting of this society was held at the Apothecaries' Hall on Feb. 23rd, Dr. J. Rose Bradford being in the chair.—Dr. James Burnet (Edinburgh) read a paper on the Therapeutics of the Ichthyol Compounds, with special reference to Ichthoform and Ichthargan. This paper will appear in an early number of The Lancet.—Mr. W. McAdam Eccles read a paper on Inguinal Trusses. Alluding to the history of the subject he said that inguinal trusses were represented on the statuettes of Egyptian gods but were not mentioned by Hippocrates. He then entered into a number of constructional details, pointing out both the characteristics of suitable and well-designed trusses and the defects in shape and materials which were occasionally met with.—A short discussion followed the reading of the paper.

Newport (Mon.) Medical Society.—A meeting of this society was held at the Newport and County Hospital on Feb. 24th, Dr. J. Howard-Jones, the President, being in the chair.—Mr. C. S. Vines showed a case of Enlarged Testis (? Tuberculous).—Dr. T. Morrell Thomas exhibited a case of Molluscum Contagiosum.—Mr. O. E. B. Marsh read notes on a case of a Calculus removed by Suprapubic Cystotomy from a pouch near the prostatic end of the urethra and showed the specimen and patient.—Mr. Vines read a paper on Ectopia Testis.—Mr. W. J. Greer exhibited Professor Jaboulay's Button for Gastro-duodenostomy and illustrated the method of using it, pointing out the respects in which he considered that it was superior to Murphy's button.—The various papers and exhibits were fully discussed by the members present.

Reviews and Notices of Books.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. New Series, No. 6. Calcutta: Office of the Superintendent of Government Printing, India. 1903. Pp. 53. Price 12 annas, or 1*s.* 2*d.*

THIS issue, which is the first report of the anti-malarial operations at Mian Mir, 1901-03, is by Captain S. P. James, M.B. Lond., I.M.S. The operations were initiated by the members of the Royal Society's Malaria Commission with the object of demonstrating that malarial fever can be prevented by practical measures based on the discovery that a particular kind of mosquito is the definitive host of the malaria parasite. The original object of the commissioners was to test the efficacy of the destruction of mosquitoes in the prevention of malaria and Mian Mir was chosen as being a very malarious station and as one in which it seemed probable that a marked reduction in the number of mosquitoes could be effected. The report is divided into three parts.

Part I. gives a brief description of the conditions under which malarial fever spreads in Mian Mir. The season of new infection in this station begins in July or early in August and the number of new infections increases steadily until it reaches a maximum in October. It is evident that anopheles culicifacies is the chief, if not the only, carrier of malaria in Mian Mir, a species which breeds chiefly in the irrigation watercourses which are running more or less throughout the year. Only two forms of the malarial parasite have been met with in Mian Mir—viz., the benign tertian and the malignant tertian forms. It has been shown by Captain James in No. 2 of the new series of the same "Scientific Memoirs" that a high percentage of the young children in the various bazaars and followers' lines are infected with malarial parasites and as the children receive no treatment whatever it may be assumed with certainty that they form the chief source from which anopheletes become infected. The prevalence of malaria is least in the lines that are furthest from a breeding place, and where consequently fewer of these mosquitoes can be found, and greatest in the lines that are nearest a breeding place.

Part II. details the operations which were commenced on April 2nd, 1902, (1) towards the destruction of the anopheletes; (2) the removal of a number of infected people to a distance from the breeding places of all mosquitoes and away from the vicinity of the barracks; (3) operations directed towards the destruction of the malarial parasites in infected individuals by subjecting such individuals to continuous treatment with quinine (especially the children in the different followers' lines); and (4) the administration of prophylactic doses of quinine to the troops. The methods employed with a view to the destruction of mosquitoes were principally confined to operations against larvæ: they consisted in keeping the sides of the watercourses smooth and free from grass for many months; in having one of the watercourses lined with brick and smoothly plastered with cement; in drying out and cleansing each branch watercourse every ten days; in pouring oil on the watercourses; and in filling in pools and emptying out water from the surface drains. Experience showed that bricking in of the old watercourses was not a success from the point of view of the destruction of the breeding grounds but that in order to secure this a very narrow channel should be built in the bed of the old one to insure a swift running stream. On account of the fact that special precautions are necessary when kerosene oil is used as a larvicide this method can only be carried out under careful supervision. In the really hot season it was found necessary to repeat the oiling of pools at least every three days as the larvæ develop rapidly and under the great heat the oil quickly evaporates. Operations appeared to show that anopheles culicifacies is able to survive the Punjab winter solely by means of "hibernating" larvæ and it was Captain James's object during the winter months to kill off all such larvæ within a wide area. By the end of February, 1903, all larvæ had been killed off within a radius of nearly two miles and he had convinced himself that no adult insects were present in the houses. But as anopheletes can be introduced into any district cleared of larvæ by flight over a comparatively long distance, by conveyance in vehicles from without the district, and in other ways, it is apparent that the destruction of these mosquitoes must be repeated every year. In order to insure that the prophylactic doses of quinine were taken by the soldiers they were paraded twice a week at the hospital and the doses were given under the supervision of a medical officer.

Part III. deals with the results. In spite of the operations for the destruction of the larvæ the number of adult anopheletes present in the houses and the number of larvæ found in the breeding-places gradually increased month by month to a maximum in September and October and then quickly decreased during November and December, although the operations were discontinued during the latter month. A similar disappearance was also noted in places where no operations were carried on. It seems doubtful whether any operations short of permanent extermination of all possible breeding-places will produce a marked reduction in the number of the anopheletes. However, the experiments in the bazaars and lines proved that even a slight reduction affects the amount of malaria to an extent which is quite measurable. As a result of the treatment with quinine no parasites were present in the children examined in October, 1902. It is generally agreed that the year 1902 was an exceptionally healthy one for all the troops in the Punjab and for this reason it was an unfavourable one for testing the efficacy of prophylactic measures by means of hospital statistics. The number of admissions for ague among the British troops throughout the cantonment of Mian Mir during 1902 was the lowest ever recorded. A large proportion of the immunity enjoyed by the British infantry must be attributed to the prophylactic issue of quinine. The changes in the troops which happened in 1902 render it very difficult to form a correct estimate of the efficacy of the operations for the destruction of mosquitoes and of the measures carried out in the artillery lines. The author regrets that from want of time he has been unable to examine films of blood from a large number of men in the British infantry and artillery respectively in order to ascertain whether a reduction in the percentage of infection of the troops themselves had taken place.

The report is an interesting one and is well worth studying in its entirety. The deductions are clearly these: (1) that the destruction of mosquitoes is difficult and expensive, though it is efficacious; (2) that the attempt to lessen the obvious sources of infection of anopheletes such as the method of treating large numbers of native children regularly with quinine, is of importance; and (3) that the use of quinine for the troops as a prophylactic (under strict supervision) is of the greatest value.

The Medical Annals of Maryland, 1799-1899: Prepared for the Centennial of the Medical and Chirurgical Faculty. By EUGENE FAUNTLEROY CORDELL, M.D. Baltimore. Published for the Society. 1903. Pp. 888.

THIS large volume was printed to commemorate the hundredth anniversary of the foundation of the Medical and Chirurgical Faculty of Maryland and was undertaken by a committee consisting of five members, Dr. William Osler, Dr. T. A. Ashby, Dr. H. Friedenwald, Dr. H. M. Hurd, and Dr. G. J. Preston. It consists of a history of the society, biographical notes on the members, and an account of the chief events of medical interest which took place in the State of Maryland from its earliest times to the end of the period under review. To the English reader the part last referred to, which is arranged under the heading Chronology (pp. 639–732), is decidedly the most interesting part of the volume. It is stated that Europeans first visited the Chesapeake in the year 1608 and sailed up the Potomac. The history of this voyage was written by "Walter Russell, Gentleman, doctor of physicke," and later in the year a second voyage was undertaken and of this an account was written by Anthony Bagnall, chirurgeon. The earliest obtainable record of a necropsy in Maryland is of one made in 1637 by a surgeon named Henry Hooper on the body of a man "killed by a tree," but in what manner we are not told. The jury of 12 found the deceased's "bloud bulke broken," and the offending tree was forfeited to the Lord Proprietor. Payments for medical services were made in tobacco and some of the earliest records relate to suing for fees and to malpraxis. It may perhaps not be generally known that Maryland was named after Henrietta Maria, Queen of Charles I., and that on the arrival of the news of the execution of that monarch Charles II. was proclaimed king by the governor of the province.

Inoculation for small-pox, which was of course introduced into England at a much earlier date, was carried on by Dr. Adam Thompson in 1738 "by a new method, the American," of the peculiarities of which we are not told. In 1765 Dr. Henry Stevenson, "the most successful inoculator in America," opened an "inoculating hospital" in Baltimore. It is interesting to note that in 1766 Dr. Stevenson collected £400 towards purchasing a "genteel statue" for William Pitt.

The first part of the volume, which deals fully with the history of the Medical and Chirurgical Faculty, appears to be a very thorough and painstaking piece of work and will doubtless prove of use to those for whom it is written but with the exception of a few scattered facts it is of purely local interest. The book contains a large number of illustrations, chiefly portraits of defunct members of the society. The reproductions appear to have been made faithfully, but taking them altogether a worse lot of portraits it has never been our lot to see; whether this is due to the fault of the artists or to a lack of comeliness in the sitters, or to both these causes, we cannot pretend to determine. The literary part of the book is distinctly above the usual standard of American medical writing.

A Text-book of Obstetrics. By J. CLARENCE WEBSTER, M.D., F.R.C P. Edin., F.R.S. Edin., Professor of Obstetrics and Gynæcology in Rush Medical College, University of Chicago, &c. With 383 illustrations. London and Philadelphia: W. B. Saunders and Co. 1903. Demy 8vo, pp. 767. Price 21*s*.

Professor J. Clarence Webster is already well known by his writings on human placentation, ectopic gestation, and the anatomy of the puerperium. It is not surprising, therefore, to find that he has written a text-book on obstetrics. The work is one of great merit, and for that part of it devoted to the science of obstetrics we have nothing but praise. Great prominence has been given to the various embryological, physiological, and pathological data of importance in connexion with obstetric medicine. In this branch of the subject it will certainly fulfil, as the author hopes, all the needs of the scientific student. The practical part of the book, however, hardly reaches the same high standard and we must confess to being somewhat disappointed with it.

The account of the development and structure of the placenta is one of the best that we have read and is most admirably illustrated. The changes which occur in the size and position of the uterus during pregnancy are well described and both in this section and in that on the changes occurring during the puerperium and in discussing the mechanism of labour the author has made great use of his own anatomical studies and of those of others. The description of the mechanism of labour, based as it is on facts and not on theories, is of great value. When the mass of speculative theories as to the causation of the different movements is swept away it is surprising how clearly and shortly the whole matter can be put.

As is usual in American text-books, the directions given for the carrying out of antiseptic details in the management of a normal case of labour strike us as unnecessarily complicated. The author does not believe that any chemical antiseptic is capable of rendering the skin sterile and he therefore advocates the wearing of rubber gloves not only by the medical attendant but also by the nurses and the assistants in all cases of labour. Elaborate instructions are given as to the sterilisation of towels, sheets, and dressings. It would be interesting in this connexion to know what results are obtained by American and Canadian practitioners in their private practice and by how many men the elaborate details described in the text-books are actually practised.

In discussing the indications for the application of forceps the author is somewhat vague and indefinite and no proper distinction is made between the use of the forceps in cases of primary uterine inertia and in cases of secondary uterine inertia. As might be expected in the writings of a graduate of the Edinburgh school of medicine, the axis-traction forceps is very strongly recommended. It is astonishing to find how much misconception still exists in the minds of many obstetric teachers with regard to this forceps. The old erroneous objection that the axis-traction forceps must produce injurious compression of the child's head is brought forward time after time, although a study of the writings of any of the men who have done so much to bring this type of forceps into general use would show that this is an entire misconception. No one who has ever had any real experience with the axis-traction forceps would willingly return to the use of the long forceps without axis-traction rods. It is surprising how little effect the writings and example of the Edinburgh school in this matter have had upon many of the teachers of obstetrics, at any rate in London. Our own experience amply bears out the statement of Professor A. R. Simpson: "If a practitioner accustomed only to the use of the old forceps will use the axis-traction forceps in one or two difficult cases he will find that it works with so much safety to the mother and child and with so much ease to himself that he will use it in every case. There is no case high or low, with presentation and position normal or abnormal, demanding forceps delivery where the axis-traction forceps may not be applied."

It is always particularly interesting in reading a work upon midwifery to see what are the author's views as to the treatment of so important and difficult a subject as that of concealed accidental hæmorrhage. With Professor Webster's account we must confess we are disappointed. We doubt if a student on reading this description would have a really clear idea with regard to the principles of the treatment and the result which the various measures recommended are intended to bring about. In cases where the cervix is rigid the author apparently is in favour of vaginal Cæsarean section. No mention is made of the use of Bossi's dilator, although this is precisely the class of case in which it is clearly indicated.

In very severe cases we are told that in most circumstances the best course is to rupture the membranes immediately with a finger or a bougie, and yet a little further down the same page is the statement: "Early rupture of the membranes is widely employed in the treatment of ablatio placentæ, but there is little doubt that the results following its application are not such as to justify its routine use." Abdominal Cæsarean section is mentioned but not the performance of Porro's operation, a much more suitable procedure in such cases of emergency.

The book is well illustrated and bound but the index is by no means so complete as it should be in a work of this size. There is much in the volume which will be read with profit by both student and teacher, but we doubt if the former will find it as useful as it might be as a work of reference when he is confronted with a difficult case in actual practice. Although he will have no reason to complain of the number of different plans of treatment referred to he will not receive as much assistance from the author in enabling him to form a definite choice between them as he might well expect, and it must be remembered that this is one of the main objects with which a young practitioner consults a text-book.

A Manual of Operative Surgery. By Sir FREDERICK TREVES, Bart., K.C.V.O., C.B., LL.D. Aberd., F.R.C.S. Eng.; Sergeant Surgeon-in-Ordinary to H.M. the King; Surgeon-in-Ordinary to H.R.H. the Prince of Wales; Consulting Surgeon to the London Hospital. New edition, revised by the Author and JONATHAN HUTCHINSON, Jun., F.R.C.S. Eng.; Surgeon to the London Hospital; Examiner in Surgery, Royal Army Medical Department. With upwards of 470 Illustrations. In two volumes. London, Paris, New York, and Melbourne: Cassell and Company, Limited. 1903. Pp. 750 and 824. Price 42s.

THE first edition of this well-known work was published in 1891 and three issues have appeared since then, but the very considerable changes that have been made in operative surgery required that the book should be entirely revised. This has been done and judging by the result we consider that Sir Frederick Treves has been wise in selecting as his coadjutor for this arduous duty Mr. Jonathan Hutchinson, jun. The distinguishing characteristic of the first edition of this "Operative Surgery" was the limitation of the modes of operation presented to the reader to those which in the author's opinion were the most valuable. In many ways this is an excellent method, for so far as the student is concerned his memory is not overweighted with a variety of different modes of attaining the same result, and so far as the surgeon is concerned the burden of choice is laid on the author of the volume and not on the reader. This is as it should be for a work intended chiefly to be used by surgeons who have not had a very extended experience and yet have to act on their own responsibility, perhaps in out of the way parts of the world. We consider that the book will be found useful by surgeons of cottage hospitals and medical officers of the navy and army who have to depend on themselves in carrying out operative procedures. Just that form and amount of assistance which they need will be given them by this work and to this end we commend it.

The very essence of the book is its practical nature. It is hardly possible to open it at random and to read a page without recognising that the author is describing a subject with which he himself is thoroughly acquainted and that he has an exceptional power of imparting to others the knowledge which he possesses. Very pertinent are the remarks in the chapter on the operator, from which we may quote: "A shakiness of the hand may be some bar to the success of an operation, but he of a shaky mind is hopeless. In the handling of a sharp instrument in connexion with the human body a confusion of the intellect is worse than chorea."

Sections are devoted to the preparation of the patient for operation and there is a useful discussion on instruments and operating tables. Mention is made of a case in a private house where four boxes and a small chest of drawers had been provided to serve as an operating table for excision of a part of the lower jaw in a heavy man.

The work is well illustrated; in this edition some of the older illustrations have been replaced by new ones.

Travaux de Chirurgie Anatomo-Clinique: Voies Urinaires, Estomac. (Clinical and Pathological Observations on Surgical Cases: Urinary System and Stomach.) By HENRI HARTMANN, Professeur Agrégé at the Faculty of Medicine, Surgeon to the Hôpital Lariboisière, Member of the Société de Chirurgie, Paris. With 113 figures in the text. Paris: Georges Steinheil. 1903 Pp. xiii.-360. Price 15 francs.

THIS volume contains a number of articles emanating from the Lariboisière Hospital of Paris and dealing chiefly with the urinary system and the stomach. Some of the articles are based on clinical observations and some are devoted to the recital of the results of pathological investigations. M. Hartmann has taken the chief part in the preparation of the book but many others connected with the hospital have assisted.

The first paper contains a description, with numerous illustrations, of the "service Civiale" at the Lariboisière Hospital. It was opened in 1901 and treats diseases of the urinary tract; it contains an out-patient department and also wards and an operating theatre. It appears to be fitted very completely for the work that has to be done there. Other articles deal with Direct Cystoscopy in the Female, Tumours of the Fatty Capsule of the Kidney, Indications, Methods, and Results of Internal Urethrotomy, Perineal Prostatectomy, the Bacteriology of Cystitis, Intravesical Separation of the Urine from the Two Kidneys, the Surgical Treatment of Lesions of the Stomach other than New Growths, the Pathological Anatomy of Cancer of the Stomach, and Duodenostomy.

The volume has in it much that is interesting and will well repay perusal by those who devote their attention to these special branches of surgery.

LIBRARY TABLE.

Annual Report of the Imperial Bacteriologist for the Year 1902-1903. Calcutta: Office of the Superintendent of Government Printing, India. 1903. Pp. 23 + 12.—This report is divided into three sections. The first deals with research work on the question of rinderpest. During the year experiments were continued and concluded for the present with a view to determine the best method of producing serum possessed of the highest protective value and in the shortest possible time. In addition to the preparation of different kinds of sera, including those for rinderpest, anthrax, and hæmorrhagic septicæmia, together with the routine work of the laboratory, the imperial bacteriologist has utilised his spare time during the last three or four years in the elucidation of certain problems such as "Whether it could be determined what are the constituents of the fifth or sixth day rinderpest bile which conferred immunity"; "Whether, if determined, they could be so collected and separately utilised as to *per se* confer immunity," and kindred questions. Section II. deals with the Applications of the Result of Research and Section III. with Administration. Under this latter heading it is stated that the major part of the officers' time was occupied in preparing rinderpest and anthrax sera, while exhaustive investigations were carried on into the etiology of barbone, a disease of buffaloes clinically known as hæmorrhagic septicæmia, with a view to discover the best method of preparing a protective serum and other methods of conferring immunity against this disease for buffaloes and cattle generally. Test experiments were continued throughout the year to determine the protective power of all sera prepared at the laboratory. With the report is issued a "Note on the different degrees of susceptibility to rinderpest exhibited by the various pure and mixed breeds of bovines and buffaloes, &c., submitted to serum testing, by the 'serum alone' and the 'simultaneous methods' during the years 1899-1903." The important question as to whether anti-rinderpest serum should be used indiscriminately or only in outbreaks of the disease is discussed. Dr. A. Lingard, the imperial bacteriologist, is of opinion that the time has arrived when the injection of serum should only be practised at, and around, the centres of outbreaks of rinderpest. He writes: "In the future let the aims of the authorities interested be to attack each centre of rinderpest as it is reported and endeavour to draw a cordon of protected cattle around each infected area." He considers that if this mode of procedure were followed the majority of outbreaks could be stamped out with a minimum mortality and the least possible expenditure of serum.

The Annual Report of the Pasteur Institute of India, Kasauli. August, 1902, to August, 1903. By Lieutenant-Colonel D. Semple, R.A.M.C., Director of the Institute. Pp. 23.—During the year under review 584 patients underwent antirabic treatment, of whom 269 were Europeans and 315 were natives. For statistical purposes these are divided into three classes: (*a*) those bitten by animals proved to have had rabies; (*b*) those bitten by animals certified by veterinary surgeons to have had rabies; and (*c*) those bitten by animals suspected of rabies. Each of these classes is again subdivided into (1) those bitten on the head and face; (2) those bitten through the exposed skin on any part other than the head or face; and (3) those bitten through the clothing. The statistical table shows that amongst the 584 patients treated there were six failures, which gives a percentage of 1·02. All the failures recorded belonged to Class (*c*). In addition to the six cases in which treatment failed four other patients (severely bitten) went too late to the institute and developed the disease during treatment and two patients succumbed after the completion of the treatment. These six cases cannot be reckoned as failures because the nerve centres were invaded by the virus of the animals which inflicted the bites before it was possible to render them immune against the disease. When the virus reaches the nerve centres it is not possible to stave off the subsequent onset by any known treatment. In a case of this kind hydrophobia sets in with certainty within a period of 14 days; not a single symptom need necessarily be present during the incubation period which follows the invasion of the nerve centres by the virus; the only index as to when invasion took place is the time when symptoms first set in. These statements are based on the information derived from experimental rabies in animals. Lieutenant-Colonel Semple points out that the only trustworthy test of a rabid brain or cord consists in inoculating an animal and waiting for the result (which generally takes 14 days) and that for diagnostic purposes it is only necessary to send a small portion of the brain, the spinal cord, or the medulla in a small bottle of sterile neutral glycerine. An antirabic serum has been prepared with a view to improve the treatment in badly bitten and late cases, by diminishing the time required to produce immunity. The serum is derived from young healthy ponies which have been highly immunised with the virus of rabies. The experiments with this strong serum gave most satisfactory results and seeing that it has the property of destroying the virus of rabies in a mixture it is reasonable to suppose that it might be valuable as a first dressing to apply to the wounds and for inoculation into the tissues around the seat of a bite; these points are under investigation. When given hypodermically to animals it has no effect in warding off rabies when the virus has been inoculated subdurally. In badly bitten and late cases the object is to confer a high degree of immunity as soon as possible. By this treatment the benefits are given of a passive immunity conveyed by using the serum of another animal which has been highly immunised, while the patient is trained to acquire the more durable active immunity which can only be attained by undergoing a series of inoculations with the virus of rabies. The principle involved in the preparation of anthrax vaccine is to obtain cultivations of anthrax bacilli attenuated to such an extent as not to convey the disease to the animals for which their use is intended but at the same time strong enough to confer an active immunity against an attack of anthrax. 560 doses of this vaccine have been sent out to applicants where outbreaks of anthrax had taken place, but particulars as to the results have not yet been collected. The information goes to show that none of the animals inoculated contracted anthrax. The anti-venomous serum is now being sent out for use throughout India. The horses used in its preparation have been immunised with cobra venom; others are now being immunised with viper venom and mixed venoms. Following up the line of Lieutenant-Colonel Semple's reasoning it is evident that children and people of feeble physique require large doses of antivenene to save them. In a case of cobra bite, when the patient is seen early and before symptoms have set in, the antivenene may be injected hypodermically in the loins. It is possible to save a patient at a much later stage by giving the antivenene intravenously. A considerable amount of ordinary bacteriological work has been carried out at the institute during the year. The report is well worthy of close study.

Cookery for Invalids and the Convalescent. Compiled by C. Herman Senn, G.C.A. Third edition. Revised and enlarged. London: The Food and Cookery Publishing Agency. Pp. 101. Price 1*s.*—This little book contains some good recipes for the preparation of food for invalids and for convalescents. Much of the teaching which it contains is quite sound—for example, the advantages of grilling are duly set forth on p. 36. The directions given for the preparation of beef-tea will be found generally useful. Exception must be taken to cheese as a suitable diet for the gouty. In the matter of jellies more information is desirable. The reader is told "to take some jelly" but not how to make it. The work does not profess to be more than a compilation and must be judged as such.

New Inventions.

IMPROVED LIGATURE.

I desire to bring before the notice of surgeons a ligature which has for some considerable time given me great satisfaction. It is made by a special process, from numerous single cocoon fibres, which produces a ligature equal in every respect to silk twist and one which has the following advantages. 1. Greater strength than other ligatures have. 2. Simplicity and ease of sterilisation; a few minutes' boiling renders it perfectly aseptic. 3. Good keeping properties; it will keep indefinitely unimpaired in the wet or dry state. 4. Absence of any tendency to slip; when tied on a vessel or a pedicle owing to the flat form the ligature assumes it has no tendency to slip off. 5. Ready temporary encapsulisation and perfect after-absorption; the process of manufacture, whilst resulting in one thread of any desired thickness which retains its entirety, does not compress the component fibres together, so that the plastic lymph thrown out around the seat of application is able to penetrate between and around each strand composing the ligature, and to this is due, I believe, the absence of those annoyances so common with ordinary forms of ligature—namely, stitch abscess and the extrusion, perhaps weeks or months after an operation, of the deep ligatures. The use of split-eyed needles with this as with other forms of ligature saves both time and trouble.

The ligature can be obtained from Messrs. Maw, Son, and Sons, Aldersgate-street, E.C., who have provided a neat metal case containing varying sizes of the ligature together with split-eyed needles adapted for each size, the whole being so constructed that without disturbing the contents perfect sterilisation can be effected by a few minutes' boiling.

Leek, Staffs. PERCY H. V. HAMMERSLEY.

AURAL SUPPOSITORIES.

IN common with other aurists I have experienced considerable difficulty in obtaining a satisfactory medium for the preparation of suppositories suitable for use in the ear. The usual cocoa-butter or glyco-gelatin bases, although fusible at the internal temperature of the body, do not readily melt when inserted into the external meatus, the temperature there being considerably lower than that of the blood. Recently I called the attention of Messrs. Savory and Moore of New Bond-street to the matter and they soon succeeded in producing a thoroughly satisfactory suppository having a fatty basis melting quite readily in the ear and yet firm in consistence. These suppositories, which I understand they have named "aurules," are furnished with silken threads to facilitate handling. Any suitable medicament can be prescribed with the basis. Those I have used are the aurulæ morphinæ compositæ. Each of these contains one-eighth of a grain of morphine and $\frac{1}{150}$th of a grain of atropine. FREDERICK SPICER, M.D. Durh.

Wimpole-street, W.

A NEW STEEL MAT.

WE have received from the "American Industries in Europe," Cromwell House, Surrey-street, Strand, a steel mat. Mats made of steel are by no means new, but the one before us presents one new feature in that it will very easily roll up and also that, contrary to the custom of the ordinary wire mats, it remains perfectly flat when spread out. The steel is said to be treated in a special manner so that it will not rust. The mats are made in various sizes and seem well adapted for the purposes for which they are intended.

CHLORAL POISONING AT PORTSMOUTH LUNATIC ASYLUM.

AT an adjourned inquiry held in Portsmouth on Feb. 25th into the cause of death of four inmates of the Portsmouth Lunatic Asylum the results of the examination of the contents of the bottles from the dispensary were given. Amongst these bottles was the residue of the medicine which had been taken by the four deceased persons, medical evidence having indicated that death was due to chloral poisoning.

Five bottles in all were submitted to analysis by the public analyst for the borough and in two of these the amount of chloral was determined by the county analyst also. The bottles were as follows. Two bottles contained chloral hydrate, one a large Winchester quart bottle and another a small glass bottle said to have been used for dispensing purposes. Both of these bottles contained 100 per cent. chloral hydrate or 437·5 grains per fluid ounce. The contents of another Winchester bottle, a bottle similar in size to the pure chloral bottle, and bearing a label which at a glance was not dissimilar, known as the stock "chloral bromide" bottle, gave on analysis: 6·3 per cent. chloral hydrate and 7·2 per cent. potassium bromide, or 27·4 grains of chloral hydrate per fluid ounce and 31·5 grains of potassium bromide. The above analytical result shows that these bottles contained the drugs as indicated by the label and as stated by the various witnesses in examination. The point to be noticed here is that a solution of pure chloral of specific gravity 1·45 (100 grammes chloral hydrate per 100 cubic centimetres of liquid) was kept in a Winchester quart bottle of exactly the same size, shape, and colour as that containing the stock solution of chloral and bromide for dispensing purposes. The contents of the two remaining bottles were submitted for analysis by both the analysts: the large white dispensing bottle, said to have contained a mixture of equal parts of the stock chloral and bromide solution and of water, contained 2·88 per cent. chloral hydrate or 12·7 grains per fluid ounce, and 4·5 grains of potassium bromide per fluid ounce; and the last bottle—a two-ounce bottle containing a fluid coloured pink and evidently slightly viscid, said to have been prepared by diluting the mixture in the dispensing bottle with half its amount of water and thus supposed to contain about 15 grains of chloral—contained on analysis 44·1 per cent. chloral hydrate or 193 grains per fluid ounce. The total amount in the bottle would thus be 386 grains of chloral hydrate if it contained exactly two fluid ounces, but as 40 cubic centimetres were given to one analyst and 23 cubic centimetres to another the total amount of liquid in the bottle amounted to 63 cubic centimetres (two and a quarter fluid ounces) and this would contain 428 grains of chloral hydrate. This bottle was shown and admitted by the witnesses to contain a mixture of the same composition as the dose given to each of the four deceased persons. It is thus evident that each person taking a dose of two fluid ounces would receive 428 grains of chloral hydrate, or about four times the fatal dose. The method of analysis used by both observers was that of decomposing a given volume of the chloral solution with an excess of caustic soda of known strength and estimating the amount of soda remaining by titrating with sulphuric acid of known strength, using litmus solution as indicator. This method gave very accurate and excellent results when practised on a solution of known strength. An attempt was made to estimate further the amount of chloral hydrate in the pink solution by a reduction method. A known quantity of the solution was placed in a flask with zinc and acetic acid. When the reaction was considered at an end a faint excess of sodium carbonate was added, then silver nitrate and nitric acid, and the precipitated silver chloride weighed. It was, however, found that after 36 hours the reduction was not complete, so that beyond proving the presence of a very large amount of chloral in the pink solution the experiment was of no quantitative value. The process, however, gave fairly concordant results using a weak solution of chloral. The question as to how the pink solution came to contain the fatal dose of chloral was not decided by the jury, but it was decided that the dispensing bottle had been tampered with, as this bottle only contained 4·5 grains of potassium bromide instead of about 15 grains. If this bottle had originally contained pure chloral and the draught bottle had been half filled from it and then filled up with water and coloured this would give a solution of the composition disclosed by analysis, as the pink solution only contained a trace of potassium bromide probably due to the bottle being used again without rinsing. What is very evident from the inquiry is that a very serious mistake has arisen probably through the circumstance that pure chloral hydrate was kept in a bottle in every way resembling (except for the slight dissimilarity in label) that in which the stock solution of chloral and bromide was kept and that this bottle was accidentally used when the other was intended to be taken. The jury returned a verdict that death was due to poisoning by chloral by misadventure, adding that the evidence had failed to show who was the person who had actually committed the mistake.

THE LANCET.

LONDON: SATURDAY, MARCH 5, 1904.

The Progress of the University of Cambridge.

ON Tuesday last His Majesty the KING, who was accompanied by the QUEEN and Princess VICTORIA, visited and declared open the new buildings which have been recently erected at Cambridge for the better accommodation and further development of the faculties of medicine, botany, geology, and law in the University. These buildings, a detailed and illustrated account of which we were able to place before our readers last week, may be regarded as the practical outcome of a movement which first took a definite shape six years ago in the form of a public communication from the Duke of DEVONSHIRE, the Chancellor of the University, in respect of the pecuniary condition and requirements of the famous seat of learning of which he is the official head. This communication must, we think, have caused a shock to the mind of a large section of our population, inasmuch as it made clear by the help of a close financial statement the deplorable fact that the University, instead of possessing the wealth indicated by its history, possessions, and associations, was sorely in need of money. The Duke of DEVONSHIRE said to the world, as resident workers at the University had been saying to each other for ten years in the various common rooms, that the resources of Cambridge were scanty and that there was no immediate prospect of their increase, while the work before it, if it was to be discharged in the future in the spirit and manner of a glorious past, must of necessity entail enormous expenditure. The revenues were falling as the expenses were rising. The financial statement showed that the endowments of the University were small and that the payments due to "The Chest" from the different colleges had been sadly lowered owing to the falling off through agricultural depression of the incomes of the colleges, so that at a time when the advance of knowledge, especially the advance of scientific knowledge, formed a conspicuous feature of the age, the University was left without any money to provide proper equipment and teaching facilities for scientific study. Buildings were needed of all sorts—laboratories, lecture rooms, examination rooms, libraries, museums, and offices. Teaching—and splendid teaching, too—as will be admitted by all who remember the work done by Cambridge physiologists, for example—was provided, but an amount of gratuitous work was being done by the lecturers that the University ought not to have expected from them. Endowment was wanted for professorships, lectureships, and readerships a fact which had indeed been admitted 15 years previously by a Royal Commission. All these things appeared plainly from the Duke of DEVONSHIRE'S communication and its accompanying financial statement, and the immediate and practical outcome was the formation of the Cambridge University Association, with the design to carry out by corporate action on the part of Cambridge graduates the objects indicated by the Chancellor as being more immediately urgent. The association met with fair support. It has collected over £70,000, which is a large sum of money even though the constituency to which appeal was made comprises a good proportion of the upper classes of the nation. If not a large yet a substantial fraction of the sum of money urgently needed has been subscribed. A few donors have been very generous, some money has been obtained, much credit has probably been given, and the four beautiful buildings, with their complete equipments for the scientific and technical work of their respective departments, have risen in the centre of the university town. This brief history of previous events explains the true significance of the visit of the KING and QUEEN to Cambridge this week. We have not here merely the monarch graciously opening new premises for worthy objects. The inauguration of the new Cambridge schools means more. It is the public sign that a practical re-endowment of the University of Cambridge, such as the Chancellor of the University showed to be inevitable six years ago, has commenced. His Majesty, in declaring these buildings open for their work, does so not only as the KING assisting in a movement of educational importance to the country but as a Trinity man, the father of a Trinity man, and the son of Queen VICTORIA, herself the first patron of the Cambridge University Association, and of Prince ALBERT, a late Chancellor of the University.

The depressing situation in the University of Cambridge, as revealed to light by the candid revelations of its Chancellor, appears to indicate considerable material neglect of the University when we remember the victorious progress of American institutions and the development of certain of our own provincial centres of education. Let us take, for example, the University of Liverpool. University College, Liverpool, has received from Liverpool £400,000, or thereabouts, during its comparatively short life, while only a fortnight ago we chronicled an event that appears to point to a promise of annual municipal support. At a monthly meeting of the Liverpool city council held on Feb. 3rd it was unanimously agreed to place £10,000 at the disposal of University College, Liverpool, as a contribution towards the expenses of the year, and there is little doubt that the precedent of assistance thus created will be followed. This is the gratifying kind of event that may be expected to happen at Manchester, Leeds, or Birmingham and the reason for such civic generosity leaps to the eyes. The people of England are now awake to the paramount necessity of good technical education if this country is to hold its own, especially against American and German competition; they can appreciate at last the benefits of a university rising in their midst. Germany and to some extent Scotland have long known the value of the local university where prohibitive prices for residental accommodation do not preclude the average citizen from obtaining the educational benefits which all allow are now his due. But there is some danger lest in the recognition of the good to be obtained from a multiplication of well-endowed universities we should become blind to the splendid services rendered to this country by Oxford and by Cambridge We must not be taken in anything that follows as belittling the newer institutions in order to exalt the older, for to do so would be a patent error, inasmuch as a large percentage of the distinguished professors, teachers, lecturers, and readers at the younger seats obtained their training and their degrees at Oxford or Cambridge. Much that is good in the local universities springs from the fact that they are local and are able to draw their revenue from the neighbourhood by proving that their work is essential to the well-being of the neighbourhood. But the very best features that they display are animated by the all-permeating spirit of Oxford and Cambridge. This is the point that seems to us to have escaped the public ken, otherwise we do not know how to explain the fact that the University of Cambridge stands in need of money. To some extent the late CECIL RHODES by his magnificent bequests to Oxford has placed the sister university in a better pecuniary position to carry on the historic work, but even CECIL RHODES by the terms of his will showed his belief that the University was in danger of senility. And now we have come to the real point. What has militated against Oxford and Cambridge in the public mind is the belief that they are mediæval survivals, supplying upon an obsolete model education which, for all purposes in future life, makes a man gracefully unfit to earn his bread and butter. How this idea arose is another story and we are not prepared to say that there has never been a time when it could not be justified in part, but it is an extraordinary fact that the idea is held now by people who, if they would stop to think, would find that not only their bishop, their banker, and the Member of Parliament who represents them are from Oxford or from Cambridge, but that their medical officer of health, their solicitor, and the man who installed their electric light, possess the same hall-mark. Why in the face of these facts, and in view of the demands made upon Oxford and Cambridge for teachers the notion should exist that the elder universities provide only facilities for the cultivation of decorative ineptitude we cannot imagine; but we take it that the action of the Cambridge University Association, as endorsed on Tuesday last by the KING, will open the minds of the public to the truth. Oxford and Cambridge to-day are very much alive and discharge their natural functions with vigour and success despite adverse circumstances, while for the most part these adverse circumstances have not been of their creation.

Moreover, it must be remembered that at Cambridge, the university with which we are to-day immediately concerned, progress has come from within. The University has received almost no money from the public in order that it might better fit itself to meet the public needs. What the great manufacturing populations have done, and are doing, for their seats of learning has been done hardly at all for Cambridge, while the recent movement for re-endowment is entirely self-started. Spontaneously the heads of the Colleges and the influential professors met together some six years ago and came to certain conclusions with regard to the existing condition of affairs. These conclusions formed the gist of the statement which the Chancellor of the University gave to the public with his declaration of the poverty of the University. We have heard that when it was proposed that the famous Senate House at Cambridge should be lighted by means of electricity a newspaper declared that this could only be accomplished "by the hanging of 12 *pedants!*" Was the printer careless or did he share the warped view of the public with regard to the apathy of the Cambridge don? From beginning to end the great movement towards re-endowment in Cambridge has been due to the action of the University, of its leaders in thought who are in residence, and of its graduates who fill busy posts in many places and many countries. This seems to us to form an enormous argument in favour of the public coming to the aid of the University. Providence helps those who help themselves, says the proverb, and surely a millionaire can frame himself upon no better model than Providence. The bravery with which the University of Cambridge has faced serious financial problems and plunged into pecuniary debt that it might discharge its moral debt to the youth of the country seems to us to deserve immediate recognition. It cannot beg save from its alumni and it cannot advertise. We trust that the gracious act of the SOVEREIGN in making a personal visit to Cambridge will bring the needs of the University to the notice of some who can help in ministering to them.

Dispensing by Medical Men.

THE proposed addition to the suggested Medical Acts Amendment Bill of clauses to prohibit registered practitioners, with certain exceptions, from dispensing or supplying drugs or other medicaments has been discussed at a meeting of the Central Division of the Metropolitan Counties Branch of the British Medical Association and the proposal has been rejected. When the notice convening the meeting was first brought to our attention we ventured to point out that it was impossible to conceive that the General Medical Council could ever devote time to the investigation of the claims for exemption. It will be remembered that it was proposed that a practitioner, under heavy penalties, should have to satisfy the General Medical Council that he practised in a district unable to support both a medical man and a druggist. This consideration, among others, no doubt prevailed with the meeting in its refusal to adopt the prohibition clauses.

For the present the matter is at an end but it is impossible to withhold a certain degree of sympathy from the proposal, if it could have been put forward in a less uncompromising form. There can be little doubt that the present practice is irksome and that dispensing entails an unsatisfactory form of labour when the busy practitioner has come in from a long round. It is not possible in very many cases for the practice to support an assistant or dispenser and the result in such poor districts is that the medical man must himself stand about in his surgery dispensing medicines which have to be sent or called for, when, if only in the interests of his patients, he ought to be resting from his labours. While most of our correspondents fully concede this point, many have urged that they have purchased a dispensing practice, that their outlay has included the expense of the surgery, and that they are entitled to obtain some return upon the capital invested. Others have expressed a strong opinion that to interfere with dispensing would be to reduce their practice, that their patients cannot afford to pay separately for advice and for medicine, that it is doubtful whether they could afford the time for separate visits to the medical man and the druggist, that the possession of a prescription might involve the employment of the same medicine long after the conditions for which it had been originally given had completely changed, and that a prescription given to one person for one disease might in course of time be handed to another with ignorant good intent. Broadly, then, the feeling appears to coincide with that originally expressed in these columns—the conditions are not yet ripe for such an innovation, the proposed change would press too hardly upon the rank-and-file of the profession. In an ideal world each profession would keep rigidly to lines of demarcation and this principle would extend to every branch of every profession. According to this ideal consultants would never be reproached with the wrongful annexation of the patients of general practitioners. Physicians would never operate, even upon tonsils or adenoids. Surgeons would not prescribe, unless for the relief of symptoms immediately following upon their operations. Obstetricians would occupy a well-defined position with no uncertainty as to whether they were physicians or surgeons and they would never undertake the general care of a case of infectious fever, even though it should arise in a child whose entrance into the world they may have superintended some years earlier. General practitioners, accepting with pleasure the cares and responsibilities assigned to them, would receive adequate remuneration to enable them to live without struggling continually to meet necessary expenses by the profits obtained from dispensing. Further, in this ideal world druggists would confine themselves to dispensing and would never, even when asked to do so, take the responsibility of prescribing or, shall we say, of advising what drugs might be taken in certain circumstances. All these conditions might conceivably obtain in an ideal world and might satisfy the public if the conditions were generally understood. Certainly every class above mentioned would benefit from the limitations suggested, since it is probable that greater concentration would lead to greater skill in every branch of work and clearly in this at least the public would benefit. But while it is pleasant to dream of Utopia it must be remembered that it is difficult to regulate human actions upon counsels of perfection suggested by dreams, and it is scarcely possible, when persuasion fails, to obtain consent to arbitrary measures. In the matter of dispensing by medical men it is unwise to forget that the public must be considered and that resentment might be aroused by sudden alterations of routine. The public may, perhaps, by degrees be educated into acquiescence, though public eduation is proverbially slow and requires reasons rather than regulations.

Further, it must not be forgotten that the suggested rules for the regulation of dispensing would have interfered by Act of Parliament with long-established custom and would have touched the interests of a large class of medical men who are already overburdened and oppressed by the necessity of heavy expenditure. This side of the question has appeared in many of the letters which we have received and it is one which cannot be ignored in any suggestions of change. While a cordial welcome should be extended to any movement which would improve the status of the medical profession as a whole, we are bound to look closely into any plan which would materially alter conditions of work. Many of our correspondents agree with our first contention that the plan would facilitate and extend the operations of the prescribing druggist. Sometimes it is urged that this is an imaginary evil, but the truth can readily be gathered by the fact that an enormous number of private formulæ employed by druggists has recently been collected and published by a contemporary to free them from the tax imposed upon patent medicines. For these formulæ to be worth protecting against taxation necessarily implies that they are frequently employed. Clearly they are not likely to be prescribed by medical men; if, therefore, they have any sale they can only be sold directly to the public by a druggist who assumes the responsibility of making a diagnosis or of treating a symptom without a diagnosis. Country practitioners have, unhappily, ample knowledge of the injury to their practices and, more important still, of the numerous risks which result from this unqualified treatment and we consider that they are right in their contention that counter prescribing should be rendered impossible before dispensing by medical men should be hampered by legislation. At present any druggist can sell anything he likes with the exception of scheduled poisons, and if a diarrhœa mixture happens to be given to a patient with typhoid fever the druggist is safe so long as he has not led the patient or his friends to believe that he possesses a medical qualification. This is the position of affairs which reformers, both within and without the ranks of the British Medical Association, should keep before them as wanting effective remedy.

The Study of Childhood.

At a time when a good deal of fermentation, real and simulated, has been excited in the public mind with regard to education it is gratifying to see that the related questions are receiving their due share of attention from the medical profession. We have before us a lecture on "Some Elementary Aims in Education" by Mr. HAMILTON HALL, delivered under the auspices of the Childhood Society in the library of the Sanitary Institute, and this will be followed by three others, respectively by Professor W. A. POTTS, Dr. D. SOMERVILLE, and Dr. H. R. JONES. It is worthy of remark that the two last-named gentlemen are diplomates in Public Health so that their selection as lecturers may be regarded as a recognition of the intimate relation which must exist between the proper upbringing of a generation and the immunity from preventable disease which it is likely to enjoy. The society to which we are indebted for the course is one of two which are, we believe, of American origin and which apply themselves respectively to the consideration of the mental and of the physical development of the young, subjects which must necessarily tend to overlap one another, although they are sufficiently distinct to be considered from different standpoints in many respects. The societies have hitherto chiefly appealed to teachers and have striven to produce a somewhat more intelligent examination of the conditions and opportunities of their calling than had previously been customary in their ranks. Endeavours have been made systematically to investigate the mental operations of childhood and their relations to growth and physical well-being, as the only safe foundations of successful teaching, whether intellectual or moral, and as the necessary bases of those habits of mind and body which it is the first object of a judicious parent or tutor to establish. There have from time immemorial been a few teachers whose insight into the minds of the children under their care has been instinctive and whose success has been proportionate to the resulting harmony; and it has been among the chief objects of the Childhood Society to confer a similar insight as a result of careful training. In this work Mr. EARL BARNES has been an eminent pioneer both in this country and in America, and there can be no doubt that a more intelligent appreciation of childhood has been among the consequences of his teaching. So far, however, it may be feared that the good results which he has obtained have been chiefly confined to teachers of the elementary or kindergarten class and that little or nothing has been done to invalidate Dr. DUKES's well-known statement that "the education of the youth of the upper and middle classes in England is the only business for which a man is not trained." An evening paper has lately contained a series of dismal complaints concerning the prospects of young university graduates who become assistant masters in private schools, and it can hardly be said that any one of the numerous correspondents upon the question has betrayed the slightest idea of the existence of any difference between teaching and education.

With the exceptions of ROGER ASCHAM'S "Scholemaster" and of MILTON'S letter to Master SAMUEL HARTLIB, the first attempt made in this country to lay down sound principles of education was that of the great philosopher, who was also a physician, JOHN LOCKE. LOCKE rightly maintained the primary importance of care of the bodily health of the young, although he was somewhat too Spartan in his notions of the means by which the desired end was to be attained. The physiology of his day, moreover, if indeed physiology could be said to exist, was too much occupied with hypotheses about animal and vital spirits, and such like, to have any clear notions of the absolute dependence of mental activity upon the welfare of a single material organ—the brain, while it is the daily increasing knowledge of brain structure and brain function which invites the physicians of our own day to carry on the work which LOCKE began, helping them to lay down principles by adherence to which the *mens sana in corpore sano* is most certain to be secured. Mr. HAMILTON HALL has kept this principle before his mind and his lecture was a most instructive one. Our only criticism upon it is that his admonitions on the subject are possibly somewhat wanting in definiteness; nor is there, perhaps, a sufficient recognition of the great differences which of necessity exist between the results which should be aimed at in the education of different classes of the community and between the methods by which these may respectively be attained. It will be conceded without difficulty by most of those who have any practical acquaintance with the subject that nine-tenths of the teaching of ordinary elementary schools—teaching which leads to progress from standard to standard and for which pecuniary grants are paid by a confiding public—is utterly useless to the enormous majority of those to whom it is imparted; even without reference to the pertinent question once printed in an official report by one of HIS MAJESTY'S inspectors, "To what purpose in after life is a boy taught if the intervention of a school vacation is to be a sufficient excuse for entirely forgetting his instructions?"

The subjects of the three remaining lectures of the present course, which also will be delivered in the library of the Sanitary Institute (the first before these lines reach the eye of the reader and the second and third on March 15th and 24th), are the Protection of Feeble-minded Children before and after School Age, Physiology in the Curricula of Primary and Secondary Schools, and Child Punishments. These subjects present many and obvious distinctively medical aspects. The teaching of physiology, in elementary schools at least, is more likely to be successful the more it avoids technicalities and is conducted by example, while it is not incapable of being so conducted as to do mischief. In America, for instance, it has been largely perverted into a vehicle for the inculcation of extreme teetotal doctrines, and the text-books in common use are of such a kind that physiologists of sound knowledge refuse to be concerned in communicating to the young the perversions of fact which they contain. As regards Child Punishments every family practitioner must have witnessed many examples of injudicious or excessive punishment and some at least of flagrant injustice. It has often been said that the average teacher is incapable of distinguishing the consequences of physical defects from those of idleness or stupidity, and that very few children with defective sight or hearing escape punishment for faults which they are wholly unable to avoid. Apart from this many parents have no reasoned convictions with regard either to the uses of punishment or to the methods by which it should be inflicted, and Dr. JONES, by whom the lecture upon this theme will be given, will render good service to many hapless children if he will condense the principles underlying the question into a form in which they may be made available by the family medical adviser who may thus be helped to rescue his younger patients from unmerited and oftentimes injurious suffering, as well as from penalties such as written impositions and the like which have certainly no tendency to the promotion either of mental development or of a love of learning.

Annotations.

"Ne quid nimis."

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL DEFENCE.

AT a meeting of the council of the Medical Defence Union held at the offices on Feb. 18th the following motion was unanimously passed:—

> That this council resolves to do all in its power to maintain the integrity of the Medical Defence Union as at present existing.

The motion was obviously passed by the council of the Medical Defence Union with an eye upon the proposed scheme of the British Medical Association for medical defence. This scheme at present is merely hypothetical and, in the words of the *British Medical Journal*, "the council simply awaits a mandate, one way or the other, from its constituencies." The policy of the British Medical Association may require the organisation by the association of a scheme of medical defence, but we may remind our readers of the good work hitherto done in the way of medical defence by the societies existing for that purpose, prominent among which has always been the Medical Defence Union. As might be expected, the Medical Defence Union shows a strong disinclination to be merged in the proposed defence department of the British Medical Association and we cannot but think that if the two defence societies at present existing in London—namely, the Medical Defence Union and the London and Counties Medical Protection Society—together with the Medical and Dental Defence Union of Scotland, could arrive at some *modus vivendi* whereby they could work together as branches of one trunk all that is necessary would be done. The matter, however, as regards the British Medical Association is one purely to be decided by the members of the Association and it remains for them to signify their pleasure with regard to the scheme. Without doubt it would be a good thing for medical defence were the existing societies to amalgamate. The British Medical Association is the largest association of medical men in the three kingdoms, but it is highly improbable that it will ever include in its ranks the entire profession of Great Britain and if it were to absorb the existing defence societies what provision would there be for those practitioners who were not members of the Association?

AN EARLY PHARMACOPŒIA.

A VERY interesting old volume has been submitted to us for inspection by Messrs. Morgan, Marshal, and Co., of Queen Victoria-street. It is a quarto copy of the Pharmacopœia dated 1677. The name of the original owner is written on a blank page within the cover, "William Shaw, 1678," and below this appears the name of "Benjn. Blake Wills, 1866," with the note, "Saved from destruction." After the title-page, Pharmacopœia Collegii Regalis Londini, is a page of dedication to King Charles II., "Dei Gratia Angliæ, Scotiæ, Franciæ, et Hiberniæ Monarchæ." Then follow four pages of a dedicatory letter to James I., which is evidently a reprint from an earlier Pharmacopœia. The names of the President, Fellows, honorary Fellows, Candidates, and Licentiates are printed, the Christian names in most instances being Latinised, though some are left in familiar English form such as Thomas, Samuel, Daniel, Nathan, Elisha, and Nathanael (*sic*). Sir George Ent was the President when this Pharmacopœia was issued, but amongst the Fellows here enumerated are to be found the names of no less than 15 presidents of the Royal College of Physicians. Apart from this claim to distinction, many of the names are of individual interest; thus we find the Marquis of Dorchester, who presented his library to the Royal College of Physicians; Francis Glisson, whose name is perpetuated in Glisson's capsule; and Nathan Paget, who was an intimate friend of Milton and was intrusted with the responsible task of selecting a wife for the blind poet. William Sydenham is to be found amongst the Permissi or Licentiates, from which class he never emerged. It would be interesting to compare the list of simples included in this volume with that at present official but this would involve much labour and would not, perhaps, tend to edification. It would be easy to express surprise at the credulity displayed in the lengthy list of animals and substances of animal origin employed in the past but an uneasy doubt as to the opinion of posterity with regard to some modern articles leads to humility and charity. More interesting occupation might be found in noting the frequent mention of drugs which are still commonly prescribed and to which experimental work has been able to ascribe definite pharmacological actions. None will regret that the Pharmacopœia of modern times is constructed upon more simple lines. Polypharmacy was rampant in 1677, as may be seen in the formula for "Theriaca Andromachi," which contains between 60 and 70 different articles, with the direction, "Misce secundum artem." Several other copies of the Pharmacopœia of this date are known in libraries and in private collections but some differ in having a longer list of booksellers on the title-page and in the correction of a misprint on p. 207, here rendered 209. The copy before us is in good condition considering its age but it shows evidence of use in stains on its pages and in the detachment of a portion of its leather binding. We trust that it may find a resting-place in some library of similar works.

THE QUESTION OF VAGRANCY.

ON Feb. 23rd Mr. Walter Long, the President of the Local Government Board, on the occasion of a visit to the Guildhall in connexion with the thirty-second annual Central Poor-law Conference, received a deputation representing the conference and also the council of the Poor-Law Unions' Association in order that the question of the increase of vagrancy in this country might be discussed. The deputation had no very definite remedial measures to propose, but on its behalf Mr. J. W. Spear, M.P., Captain Griffith Boscawen, M.P., Mr. J. Brown, and others expressed the wish that a commission or departmental committee should be appointed to consider the whole subject and suggested the more general establishment of labour colonies and the desirability of taking steps to prohibit the association of children with the wanderings of habitual vagrants. In his reply Mr. Long spoke of the complexity of the issue which had been raised and said that he welcomed the deputation as a proof of the fact that those who gave especial consideration to this subject had come there in the hope that a way out of the difficulty might be found. He viewed, however, with some apprehension and misgiving the absence from the programme of the deputation of anything more than a rather vague hope that an inquiry might produce some possible remedy. He was not going to refuse an inquiry but he believed it would be best conducted conjointly by the Local Government Board and the Home Office and he promised at once to consult the Home Secretary in order that some definite course might be decided on. It may be worth while to consider briefly some of the points with which such an inquiry ought to deal. At the outset it must be recognised that tramps are not all of one kind and that while a few of them are engaged in a genuine search for work the remainder are animated only by a desire to live at the expense of someone else. It is impracticable to treat these two classes in the same way. For the former should be provided facilities in the way of labour bureaus which would enable employers to be brought into communication with those who desire to serve them and in special cases relief works might be necessary. For the latter only the most drastic treatment will suffice. Indiscriminate almsgiving by the general public should be discouraged as much as possible and, in particular, begging through the direct or indirect agency of children should be checked by removing such children from the control of those who thus abuse the parental relation. Vagrants who live, as so many do, by petty thieving or by terrorising women must be dealt with as the criminals they are and compelled to exchange the life of vice, dirt, and laziness of the common lodging house for one in a penal labour settlement. It is true that, as Mr. Long remarked, labour colonies in Germany, France, Belgium, and Holland have done little or nothing to reduce vagrancy and the same may be said of the attempts so far made in this country, as, for instance, by "General" Booth at Hadleigh. But the defect in these cases has been a want of thoroughness which can be overcome by means of suitable legislation and Mr. Long holds out some hope that this legislation may eventually be forthcoming.

DIPHTHERIA AND ANTITOXIN.

THE weekly bulletin of the health department of Chicago for the week ending Feb. 13th contains some interesting figures as to the death-rate of cases of diphtheria treated with and without antitoxin. The figures deal with two periods, the one before antitoxin was introduced—namely, from 1888 to 1895—and the other during the use of antitoxin—namely, from 1896 to 1903. The total number of deaths from diphtheria in the former period was 11,438, while in the latter period it was 6083, being a decrease of 47 per cent. The average annual population during the former period was 1,100,931, while during the latter period it was 1,672,042. The deaths from diphtheria per 10,000 of the population were in the former period 12·45, while during the latter period they were 4·55. Thus the latter period showed an increase of population of 52 per cent., while the deaths from diphtheria showed a decrease of 63·4 per cent. Between Oct. 5th, 1895, the date of the first case of diphtheria which was treated with antitoxin, and Dec. 31st, 1903, the health department treated 7435 cases of bacteriologically verified diphtheria, of which number 479 died, a mortality-rate of 6 44 per cent. The average mortality of diphtheria cases treated without antitoxin still remains at about 35 per cent. The bulletin goes on to give figures showing how much more satisfactory is the action of antitoxin when the case is treated early. Thus, of 586 cases treated on the first day of the disease there were only two deaths, a mortality-rate of 0 34 per cent., while of 936 cases treated later than the fourth day there were 216 deaths, a mortality-rate of 23·1 per cent. The bent of mind which, in the face of statistics such as these and similar ones which are reported from other countries, can argue against the value of antitoxin must indeed be strange.

"VINCENT'S ANGINA" WITH DESTRUCTION OF THE SOFT PALATE.

IT is not sufficiently known that besides diphtheria there is a number of membranous inflammations of the throat. One, due to the combined infection with a fusiform bacillus and a spirillum, was described by a French writer, Vincent, and is named after him. Many papers on it have been written in France, where it is well recognised. It consists of ulceration with the formation of membrane. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* Professor B. Auché states that during last year he saw several cases both in hospital and in private practice. He relates a remarkable case which appears to be unique in the occurrence of total destruction of the uvula. A boy, aged 12 years, was admitted to a children's hospital on Feb. 11th, 1903, with a membranous sore-throat of four or five days' duration. The temperature was 100·4° F. He was sent to the diphtheria wards and antitoxin was injected. On the following day, when he was first seen by Professor Auché, the face was slightly pale but the general state was good. Dysphagia, salivation, and slight fœtor of the breath were present. The right tonsil was covered with a downy membrane of a dirty yellowish-brown colour. The superficial part was friable and easily detached, leaving an adherent whitish coat. Beneath was an ulcer two or three millimetres deep with red, perpendicularly cut borders. The free margin of the palate on the right side and the right margin and anterior surface of the uvula were covered by a thin yellowish-white membrane resting on a superficial ulcer. The left tonsil was very red and swollen; its upper third was covered by a thin yellowish membrane which was difficult to detach. Beneath was a red, eroded surface which bled easily. The submaxillary glands, especially the right, were slightly enlarged. There was no coryza. On the 13th the whole uvula was covered by membrane resting on a superficial ulcer. The temperature was 99·5°. Bacteriological examination showed in parts of the membrane almost exclusively fusiform bacilli and spirilla; in other parts these microbes were mixed with staphylococci and streptococci. On the 16th the tonsillar ulcers were deeper and the summit of the uvula was destroyed. The general condition was good. On the 17th the bacilli and spirilla were still abundant but the diphtheria bacillus was found in small numbers. On the 20th the uvula was represented by a stump two millimetres long covered by membrane. On the 24th the uvula was completely destroyed and its base was covered by a thin opaline membrane. The tonsils were slowly becoming cleared. On the 28th the base of the uvula was completely, and the right tonsil was partly, cicatrised. On March 3rd the throat was completely healed. At the same time as the patient was taken into the hospital his brother, aged five years, was admitted with the disease in a milder form. Only the right tonsil was affected and by Feb. 28th he had recovered. In his case also the diphtheria bacillus was found in small numbers some days after the other organisms were discovered in abundance. Evidently both boys were infected with diphtheria in hospital in spite of the injection of antitoxin. But the diphtheria bacilli were never abundant and apparently did not modify the local or general condition. Vincent has observed the association of diphtheria with his angina in three forms: sometimes the diphtheria was the primary affection, sometimes the angina was, and sometimes both affections occurred simultaneously.

HANDWRITING AND PRESCRIPTIONS.

THE illegibility of many prescriptions cannot, we fear, even in the eyes of the unlearned, be attributed entirely to the unaccustomed symbols for drachms and ounces. Whether the handwriting of the medical profession as a body is worse than that of any other equally large body of men we do not know; certainly its official writings as evidenced by prescriptions cannot compare with the clerical productions of the sister profession of the law. In the latter case, of course, business documents are written largely by persons who have little other qualification than the possession of a clear handwriting. Obviously a medical man cannot carry his own clerk about with him to substitute a leisurely and legible writing for the hurried characters of the busy medical man, so that the performance of the lawyer's office will always outshine the scrawl from a patient's house. Yet the matter is really one admitting of such serious accidents that medical men should take special pains to write clearly. Some persons believe that prescriptions are badly written on purpose that they may convey no meaning to the patient; that his faith in the medicine, in fact, may not be interfered with by too close a knowledge of its constituents. Such an object, however, can be equally well achieved, if it is ever desirable, by substituting elaborate chemical denominations for simple and more commonly used names of drugs. As matters are at present we have a shrewd suspicion that it is often only the sagacity and carefulness of the druggist who dispenses a prescription which prevent the concoction of something far different from that which the hurried and illegible writing of the practitioner intended to convey. In an age of such utilitarian ingenuity as the present it is extraordinary that the inventor has not yet come forward whose device will make it impossible for medical men to write badly. The typewriter is a boon but it is not portable. A correspondent suggests that practitioners might keep printed a certain number of the prescriptions that they most frequently employ and these could easily be carried in the pocket-book. Unfortunately even this proceeding would have but limited scope, for many persons would refuse to believe that proper individual care had been given to their cases if the prescriptions with which they were presented were in anything but the illegible characters to which they are accustomed.

TRAUMATIC HÆMATORRHACHIS.

In the *Edinburgh Medical Journal* for February Dr. A. Miles and Dr. J. C. Carr have described a case of traumatic hæmatorrhachis which presents several points of interest. A dock labourer, aged 36 years, was admitted to hospital on Oct. 6th, 1900, at 10 A.M. On the previous day, at 4 P.M., while heaving a heavy sack over his shoulders, he felt a jerk as if something gave way between the shoulders. After this his back was painful but he worked until 5 o'clock. During the night he slept but in the morning he was prevented from going to work by pain and stiffness between the shoulders. When he coughed he felt a sensation "like the shock of a galvanic battery" from the place in the back where he was hurt down the spine and legs to the toes. He walked to the hospital, a distance of half a mile. On admission the dorsal and cervical spine was rigid. To turn the head he rotated the shoulders. The upper two or three dorsal spines were tender. He walked up two flights of stairs to the ward. About 5 P.M. he coughed and felt the same "galvanic" pain as before. Soon a feeling of numbness over the whole body followed. The upper limbs were moved with difficulty and the range of movement was much restricted. The attitude characteristic of lesions of the first dorsal segment was assumed: the upper arm was slightly abducted, the elbow-joint was acutely flexed, the forearm lay across the thorax semi-pronated, and the fingers were slightly flexed. The lower limbs were completely paralysed. Respiration was entirely diaphragmatic. Sensibility was lost below the third rib and partially on the inner sides of the arms. The knee-jerks were absent and there was retention of urine. The pulse was 60, full, and strong, the temperature was 102° F., and the respiration was from 16 to 20. On Oct. 7th the abdomen gradually became tumid and tympanitic, the respiration was 32 and laboured, the pulse was 96, and the temperature was 102·6°. There was mucus in the trachea which was expelled with difficulty. The spinal pain and tenderness persisted. He was most comfortable when his head was supported by pillows. On the 8th the pupils were contracted, the respiration was 46, the pulse was 110, and the temperature was 103·6°. As the paralysis appeared suddenly about 24 hours after the injury hæmorrhage at the level of the seventh cervical or first dorsal vertebra, extradural or into the substance of the cord, was diagnosed. To relieve the pressure on the cord an operation was performed. Chloroform was taken without difficulty. He was placed in the prone position and the seventh cervical and first dorsal vertebræ were exposed by a mesial incision and clipped off with bone forceps. The laminæ were partially sawn through and the division was completed with bone forceps. A clot of the shape and size of the bowl of a dessert-spoon was removed from between the dura mater and the bone. The cyanosis diminished. There was considerable venous hæmorrhage from vessels between the dura mater and the bone in front of the cord. After plugging with iodoform gauze the wound was partially sutured. On recovering from the chloroform the patient talked incoherently but never completely regained consciousness. Respiration became more and more difficult and death occurred at 8.25 P.M. At the necropsy the bodies of the fifth and sixth cervical vertebræ were found to be separated. Blood had passed down and between the dura mater and the bone and had collected opposite the arches of the first and second dorsal vertebræ. There was no fresh bleeding after the operation. The points of interest are: (1) the effort of heaving the sack caused partial separation of the bodies of the fifth and sixth cervical vertebræ with extradural hæmorrhage; (2) not until 24 hours later were there pressure symptoms; and (3) in spite of the relief of pressure the patient died.

THE MANAGERS OF THE METROPOLITAN ASYLUMS BOARD AND THE MEDICAL OFFICERS OF THE BOARD.

It seems to us that there may be friction between the medical officers of the Metropolitan Asylums Board and the managers of the Board if the attitude of the managers continues to grow in oppressiveness. We have lately chronicled the high-handed behaviour of the Board towards certain junior members of the medical staff; now the position of all the medical officers appears to be threatened. Lighting and coals are for the future to be supplied only upon an allowance and the allowance is, we are informed, inadequate for those who have houses to keep up, while certain minor services, such as inside window cleaning and charing, hitherto rendered by the porters in the pay of the Board, are now to be done by persons obtained from outside and to be paid for by the medical men. The limitations will fall hardly upon certain seniors among the medical staff of the Board and we recommend these gentlemen to make a clear presentment of the matter to the Local Government Board and to ask advice as to their proper procedure. If, and this we presume was the case, the medical men took service under the Board with a promise of gratuitous lighting, coals, and washing, it seems to us that an extreme, if not an illegal, step has been taken by the managers in allocating to the medical men supplies which will entail loss upon certain of them. We do not advocate waste but we are told that the supplies to be granted are insufficient. We all know that the Metropolitan Asylums Board must practise economy, want of business capacity having led it into mis-spending of money; but because the Board has overspent itself on building schemes there is no reason why it should fine its medical officers. If the medical profession gathers the idea from such occurrences as those we detail that the policy of the Board is to repudiate its contracts and "to go for the doctors"—these, we hear, were the words used by one manager—medical men of any standing or ambition will not compete for service with the Board. And when this position is reached and a time of serious epidemic arrives he public will let the Board know what they think of its policy.

A CASE OF OVARIAN HERNIA WITH TWISTED PEDICLE IN AN INFANT.

A case of some interest is recorded by Dr. Julius Schnitzler in the *Wiener Klinische Rundschau*, No. 44, 1903. In an infant a few days after birth a small swelling of the size of a bean appeared in the left inguinal region whenever the child cried but it could always be easily replaced. During six weeks compression was exercised by means of a band without result. On March 25th, 1903, the child, being then six months old, was attacked by gastro-enteritis and the swelling came down again on crying. In the afternoon of the same day the parents found that they could not replace it. On the next day a medical practitioner was called in and finding it impossible to reduce the tumour referred to Dr. Schnitzler who saw the child in the evening. He found an irreducible tumour of the size of a walnut in the left inguinal region extending into the labium majus on that side. This tumour was tender to pressure and the child was somewhat restless but otherwise quite healthy, symptoms of peritoneal irritation being entirely absent. Although the bowels were freely opened, taking into consideration that the tumour had been irreducible for 36 hours, and that it was increasing in size, Dr. Schnitzler decided to operate. On cutting into the hernial sac some blood-stained fluid escaped and the contents were found to consist of the left ovary and tube with part of the broad ligament, the ovary being larger than that of an adult and presenting some slight superficial patches of necrosis, the result of a torsion of the pedicle through 360°. The inguinal canal was so wide that no pressure was exerted on the pedicle, which was then drawn down and ligatured beyond the site of torsion and the ovary and tube were removed and radical cure was performed. Healing took place by first intention. Dr. Schnitzler was able to find two other recorded cases of hernia of the ovary with twisted pedicle. All these cases were in infants in the first few months of life. In none of them were there any signs of intestinal obstruction or of peritonitis and he suggests that an irreducible hernia in a female child without these symptoms indicates the probability of this condition and should be operated upon.

SUBSTITUTION IN THE SPIRIT TRADE.

WE note that in the House of Commons on Feb. 22nd Mr. Kilbride asked the Chancellor of the Exchequer whether he would appoint a committee of analytical experts to fix a legal standard in the case of whisky, such as is done in the case of other articles of consumption, in order to protect the public against spurious substitutions. To this the Chancellor of the Exchequer is reported to have replied that the Board of Inland Revenue did not think that it would be of any practical use to attempt to fix a legal standard for whisky. There was already, he added, a legal standard of strength below which whisky may not be sold without notice and other conditions must necessarily vary according to the taste of the consumer. We can only say that this reply recalls the remark of the late Archbishop of Canterbury that "this is not a very brave Government." We recognise that if a legal standard were adopted it would throw a considerable amount of work on the Government officials, but is that any reason why the public should continue to be deceived on the gigantic scale which the blending of foreign spirit with genuine grape spirit and genuine malt spirit respectively amounts to? Since at present there is no control directed with regard to the quality of foreign spirit so employed it is not surprising that maddening spirituous liquors are to be found upon the market. We long ago called attention to this matter and we do not agree with the Board of Inland Revenue authorities that it would not be of any practical use to attempt to fix a legal standard for potable spirits. We feel convinced that a committee of analytical experts would be able to give a valuable opinion upon this point which would reverse this extraordinary view. If this view be correct what remedy have we against the employment of pernicious spirit for blending purposes? If, as is stated, chemical analysis does not afford a trustworthy means of differentiating the genuine from the false let us at least demand honesty of description upon the label. As a matter of fact, we recorded last week a case in which a conviction was obtained against a firm of refreshment contractors for selling as brandy a spirit which proved on analysis to be not genuine brandy—that is to say, the spirit was "not of the nature, substance, and quality of the article demanded by the purchaser." What have the Government and the Inland Revenue authorities to say about this decision and about this successful action taken under the Sale of Food and Drugs Act? We should like to ask two more questions. If it were shown that a sample, say, of brandy taken under the provisions of the Sale of Food and Drugs Act was not genuine and the seller appealed on the question of the analysis to the Government referees, would they undertake the analysis of the third sample set apart for that purpose and give an opinion? If not, to whom should the appeal be directed?

A BILL FOR THE REGISTRATION OF NURSES.

A BILL has been introduced into the House of Commons by Dr. R Farquharson which proposes to regulate the qualification of trained nurses and to provide for their registration upon lines somewhat similar to those adopted in the case of midwives. The body, however, which it is suggested should assume in relation to nursing the position now filled with reference to midwives by the Central Midwives Board is to consist, according to the Bill, of no less than 31 members, of whom seven are to be medical men, 23 matrons or nurses, and one either a medical man or a nurse. The medical men, it is proposed, shall be appointed, one by the Privy Council, five by the General Medical Council, and one by the British Medical Association. The nurses, except one to be appointed by the Privy Council, are to represent various interests connected with nursing. There are more nurses than midwives, truly, but even then the reason for making the council so large is not apparent and the difficulty of securing the attendance and harmonious working of so large a number during the early years, when the bulk of the work has to be performed, would be very great. The representation of numerous, possibly conflicting or rival, interests by different persons may be sound in principle but it does not lead to the rapid despatch of business, even when there is power, as is proposed in the Bill, to delegate authority to an executive committee. It may be desirable that the public should be able to judge to some extent of the qualifications of women calling themselves nurses by the aid of a test easily applied. Whether the proposed Bill contains practical machinery for bringing this about is another matter. It is to be observed with regard to the attendance of members that the seventeenth section of the Bill provides that "There shall be paid to the members of the council such fees for attendance and such reasonable travelling expenses as shall from time to time be allowed by the council."

EPSOM COLLEGE.

WE have received from Dr. C. Holman, the treasurer of Epsom College, an abridged prospectus of the school, with a letter drawing attention to an epitome of successes during the past ten years. During this period no fewer than 24 open scholarships have been gained at the Universities of Oxford and Cambridge; 35 boys have passed the preliminary scientific examination for the degree of M.B. of the University of London, about half being in Division I.; 129 have passed the matriculation examination of the University of London, the majority in Division I. (one in honours); 81 higher certificates (with 22 distinctions) and 276 lower certificates have been gained at the examination conducted by the Oxford and Cambridge Schools Examination Board; five boys have passed the intermediate science examination and 73 have obtained South Kensington certificates in the art examination in drawing. As Dr. Holman observes, such a record out of a school of about 230 boys is a credit to the teaching staff and to the pupils themselves. The two illustrations of the old buildings and of the new lower school give a very fair idea of the college which stands in its own estate of over 80 acres, of which over 20 acres are devoted to grounds for recreation, cricket, and football. There are a detached infirmary containing about 40 beds, a laundry with a room for drying wet clothes and flannels, a swimming bath which has recently been reconstructed at a cost of over £1000, three (chemical, physical, and biological) laboratories, a gymnasium, and a carpenter's workshop. The college not only has the patronage of the King but members of the Royal Family have taken a personal interest in the school. His Majesty laid the foundation-stone of the lower school a few years ago and last year the Prince of Wales paid a visit to the college and expressed to Dr. Holman his satisfaction at all he saw. The very large number of scholarships and exhibitions open to boys leaving the school should be an attraction to persons with limited incomes. There are nine medical scholarships at the hospital schools in London, ranging in value from 120 guineas to £150, and nine scholarships ranging in value from £27 to £60. Some of the foregoing are restricted to foundation scholars. The school fee is 75 guineas a year but sons of medical men are charged only 65 guineas. The college is managed by a council of 30 governors, many of whom, as will be seen by a glance at the prospectus referred to, have risen to eminence in the medical and other professions, thus parents may safely leave the interests of their sons in the hands of this body. The prospectus has, we understand, been freely circulated amongst members of the medical profession and if anyone has consigned his copy to the waste-paper basket before reading these comments he can obtain another on application to the bursar at No. 3, the College, Epsom.

ANTI-MALARIA MEASURES AT ISMAILIA.

EARLY in the year 1902 the Suez Canal Company, through its chairman, Prince d'Arenberg, asked Sir Alfred Jones, chairman of the Liverpool School of Tropical Medicine, to allow Professor Ronald Ross to proceed to Ismailia, there to advise upon a method of ridding the town of mosquitoes. The school committee agreed and Professor Ross accordingly arrived at Ismailia on Sept. 17th, 1902. Two medical officers of the Canal Company, Dr. Pressat and Dr. Dampeirou, had already discovered the presence of the anopheles. Professor Ross confirmed their observations, made a careful investigation into the various breeding places of mosquitoes, and suggested a plan of campaign. His recommendations have been carried out with great success and from a report of the scheme and its results written by Professor Rubert W. Boyce, which is now before us, we learn that the number of cases of malaria has been reduced from 2284 in 1900 to 209 in 1903, while in this latter year, for the first time, no deaths from malaria are recorded among the European population. Professor Boyce compares the success thus achieved with that attained in Havana by the Government of the United States of America. Professor Boyce himself visited Ismailia this year and made a tour of inspection. Breeding places for mosquitoes were found to be more common in the better class quarters than in the poorer quarters, owing to the presence in the former of baths, fountains in the gardens, cesspools, and waste-water receptacles. Professor Ross had inaugurated two anti-mosquito brigades, one the drain brigade whose duty it is to keep all drains clear, and the other the petroleum brigade whose duty it is to add petroleum to all collections of water which could not be removed. The procedure is as follows, a typical house and garden being taken as an example. Once a week the petroleum brigade visits the house and pours a mixture of crude and ordinary petroleum into all collections of drain and waste water which do not soak away during the day. Petroleum is poured into the water-closets and into the pits which receive the bath and slop waste water. The garden fountain is emptied as far as possible and petroleum is poured into it, the basin being refilled after 12 hours. Stable drains, washing troughs, and all waste-water receptacles are flushed or emptied and petroleum is added. In addition to these measures a considerable strip of low-lying marshy land has been filled up with sand, thus preventing the formation of pools of stagnant water. As Professor Boyce points out, these measures are in reality only an extension of measures of sound sanitation. The report is of great interest and should stimulate the authorities of many of our colonial towns, especially in West Africa, to take similar steps to those recorded in it. If Ismailia and Havana, which latter was notoriously plagued with malaria and yellow fever, have been rendered so hygienic as is the case, there is surely no reason why other towns should not go and do likewise. In this connexion Dr. J. W. W. Stephens's article on anti-malarial operations at Mian Mir, which appears at p. 637, and the report by Captain S P. James, I.M.S., which is reviewed at p. 659, may be studied with advantage.

MEDICAL AND DENTAL DEFENCE IN SCOTLAND.

THE Medical and Dental Defence Union of Scotland, Limited, was formed in May, 1902, and the first annual general meeting was held in Glasgow on Dec. 18th, 1903, by which time there were more than 500 members. The registered office is at 108, West George-street, Glasgow, the secretary and treasurer being Mr. William Young of that address. The executive council has four presidents—namely, Professor A. R. Simpson (Edinburgh), Professor William Stephenson (Aberdeen), Dr. James Finlayson (Glasgow), and Professor J. A. C. Kynoch (St. Andrews). There are many names on the list of vice-presidents, central council, and committees. Four district councils have been formed—namely, for Edinburgh, Dundee, Aberdeen, and Inverness. The objects of the union are:—

(*a*) To protect, support, and safeguard the character and interests of legally qualified medical and dental practitioners and for that purpose to raise or defend actions in name either of any member or of the union. (*b*) To advise members in regard to questions which may arise in the practice of the medical or dental professions and to defend members when attacked. (*c*) To promote honourable practice. (*d*) To consider, originate, promote, and support legislative measures likely to benefit the medical and dental professions and to oppose all measures calculated to injure them, and for these purposes aforesaid to petition Parliament and take such other steps and proceedings as may be deemed expedient.

The subscription is 10*s*. per annum, payable each year on the anniversary of admission as a member and meantime there is no entrance fee. Members may resign at any time on giving two months' notice. Under the articles of association the utmost liability of any member for subscriptions, or in the event of winding up, is £1. The fundamental differences which exist between the laws of England and those of Scotland in many important respects, and the conviction that Scottish practitioners will be protected more adequately in a purely Scottish society, are held as justifying the existence of this union. At the general meeting reference was made to 21 cases in which the union had given advice or otherwise taken action; only one of these cases seems to have been brought into court and proceedings were at that date still going on.

THE INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

IN THE LANCET of Feb. 13th, p. 455, we announced that the First International Congress on School Hygiene would be held at Nuremberg from April 4th to 9th. Organising committees have been constituted in each of the European countries, in the United States of America, and in Japan. The offices of the English organising committee are at the Parkes Museum, Margaret-street, London, W., Sir Lauder Brunton being the president and Dr. James Kerr the honorary secretary; there are also numerous vice-presidents and members of committee. English, French, and German will be the official languages of the Congress. The

Transactions, which will be duly published, will no doubt be valuable to all who are interested in the subject of education. The work of the congress will be distributed between general meetings and meetings of sections devoted to the following ten subjects:—(1) The School Building and its Furnishings; (2) Hygiene of Residential Schools; (3) Methods of Hygienic Investigation and Research in School; (4) the Physiology and Psychology of Educational Methods and Work; (5) Instruction in Hygiene for Teachers and Scholars; (6) Physical Education and Training in Personal Hygiene; (7) Contagious Diseases, Ill-health, and Conditions affecting Attendance; (8) Special Schools, including those for Feeble-minded, Blind, Deaf, Dumb, Cripple, Invalid, and Exceptional Children; (9) Out of School Hygiene, Holiday Camps and Schools, the Relations of the Home and the School; and (10) the Hygiene of the Teaching Profession. At the general meetings of the whole congress there will be addresses on the following subjects: What has Ophthalmology accomplished for School Hygiene and what still remains to be done? by Professor Hermann Cohn (Breslau); the Present Position of School Hygiene in Norway, by Professor Axel Johannessen (Christiania); the Personal Health of the Teacher and its Influence on the Scholars, by Dr. Le Gendre (Paris); the Organisation of the Elementary School Population according to the natural working capabilities of the children, by Dr. Sickinger (Mannheim); the Duties and Preparation of the School Medical Officer, by Dr. Liebermann (Budapest); and the Prevention of Infectious Diseases in School, by Professor Hueppe (Prague). There will be an exhibition, including all that appertains to education work, school structures, and furnishing. The subscription fee for a card of membership entitling the subscriber to all the privileges of the congress is £1 1*s*. Subscriptions may be paid to the secretary of the English organising committee at the Parkes Museum.

THE annual dinner of the Medical Society of London will be held on Tuesday next, March 8th, at the Whitehall Rooms, Hotel Métropole, at 7.30 P.M. The President, Dr. F. de Havilland Hall, will be in the chair and will be supported by the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the President of the Royal Medical and Chirurgical and other medical societies, the Directors-General of the Navy and Army Medical Services, the Principal of the University of London, the Regius Professor of Physic in the University of Cambridge, Sir Thomas Smith, Bart., Sir R. Douglas Powell, Bart., Sir G. Scott Robertson, K.C.S.I., and other distinguished guests.

THE annual clinical debate of the Chelsea Clinical Society will be held at the Chelsea Dispensary, Manor-street, King's-road, London, S.W., on Tuesday, March 8th, and Tuesday, March 15th at 8.30 P.M. The subject selected for debate is "Internal Secretion" in Disease and in Treatment. The following gentlemen will speak:—First night, March 8th: Sir Lauder Brunton, Sir Victor Horsley, Dr. H. D. Rolleston, and Dr. A. E. Wright. Second night, March 15th: Dr. A. Macfadyen, Dr. R. T. Hewlett, Dr. W. Hale White, and Dr. J. Rose Bradford. The meetings will be open to all members of the medical profession.

THE medical officer of health of the Cape Colony states that for the week ending Feb. 6th no case of plague was recorded throughout the Colony. Plague-infected rats were found at Port Elizabeth and Queenstown, but of 245 rats examined during the week in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on Feb. 26th states that for the week ending Feb 25th there were three cases of plague and two deaths from the disease.

A MEETING will be held in the Mansion House on Friday, March 11th, at 3 P.M., in support of the appeal for funds for the removal of King's College Hospital to South London. The Right Hon. the Lord Mayor will preside and will be supported by, among others, the Archbishop of Canterbury, the Bishop of Rochester, Archbishop Bourne, Lord Methuen, Sir Savile Crossley, the Rev. A. C. Headlam, Principal of King's College, Dr. David Ferrier, senior physician to the hospital, and Mr. W. Watson Cheyne, senior surgeon to the hospital.

AMONG the 15 candidates selected by the Council for the Fellowship of the Royal Society are Dr. T. G. Brodie, professor of physiology at the Royal Veterinary College and professor-superintendent of the Brown Institute; Dr. G. H. F. Nuttall, university lecturer in bacteriology and preventive medicine at Cambridge; and Professor A. E. Shipley, the well known biologist, university lecturer at Cambridge upon invertebrate morphology.

THE annual meeting of the East London Nursing Society will be held at the Mansion House on Tuesday afternoon, March 15th. The chair will be taken at 3 o'clock by the Right Hon. the Lord Mayor. Motions will be proposed or supported by the Ven. the Archdeacon of London, Dr. Robert Hutchison, Mr. John Tennant (chairman of the society), and others.

THE annual general meeting of the London and Counties Medical Protection Society will be held at 31, Craven-street, Strand, London, W.C., on Friday, March 11th, at 4.30 P.M., when in view of the proposal that the British Medical Association shall undertake medical defence a large attendance may be expected.

THE Local Government Board for Scotland reports that during the period Feb. 16th to 29th inclusive 242 cases of small-pox were notified to it. The local incidence of the disease is heaviest in the borough of Greenock where the cases amount to 9·97 per 10,000 of the population.

A DECIDED change for the better has, we are glad to hear, taken place in the course of the illness of Sir Samuel Wilks, so that confident hopes are now entertained of his recovery. During the last few days his strength has increased and he has been able to take more nourishment.

MR. G. E. Richmond, M.D., B.S., B.A., B.Sc. Lond., D.P.H. Camb., has been appointed demonstrator of hygiene and public health at University College, London.

ROYAL MICROSCOPICAL SOCIETY.—At the meeting of the Royal Microscopical Society held on Feb. 17th, the secretary read for Mr. E. M. Nelson a paper on the Vertical Illuminator and the Influence of the Antipoint on the Microscopic Image. Various methods of obtaining vertical illumination were described, with especial reference to the portion of the optic axis at which the reflector was placed. Mr. Keith Lucas showed a microscope stand made by himself in which the various motions were produced by means of geometric slides. He said that the principle had been applied to reading microscopes but not to biological microscopes so far as he was aware. He claimed for the system the following advantages: (1) cheapness of manufacture; (2) impossibility of the movement becoming shaky from wear; and (3) optical alignment of the body tube with the substage fittings.

THE ROYAL VISIT TO CAMBRIDGE.

MARCH 1st, 1904, was an interesting and memorable day for the University of Cambridge when His Majesty King Edward VII., accompanied by Queen Alexandra, inspected and opened the new buildings recently erected for the instruction of students in medicine, botany, geology, and law. We described the medical school in detail last week and excellent photographs taken by Mr. Palmer Clark of Cambridge have enabled our readers to form a good idea of the buildings.

In the interesting ceremonies, which occupied the afternoon, as well as in the Congregation in the Senate House in the morning, a distinguished gathering of members of the medical profession, including the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England, played a conspicuous part and in the mass of scarlet robes everywhere visible the gown of the Doctor of Medicine of Cambridge naturally predominated. That medicine should be largely represented upon such an occasion was to be expected, for not only did the opening of the new medical schools form the first item upon the programme of the afternoon, to be followed by similar ceremonies in the departments of the kindred sciences of botany and geology, but the geological museum, a vast building filled with cases of specimens too numerous for more than cursory inspection in the course of an afternoon, has as its nucleus two cabinets of fossils bequeathed by John Woodward who took his degree as a doctor of medicine at Cambridge in 1695 and whose somewhat vigorously conducted quarrels with Sir Hans Sloane and others earned him a character for eccentricity, as well as for prodigious and recondite learning, in the early part of the eighteenth century. It was as Woodwardian Professor that Adam Sedgwick began the work which had remained undone since Woodward's day, and in the same capacity Professor T. McK Hughes invited King Edward to unveil Sedgwick's statue by the late Onslow Ford. The organisation of all the ceremonial of the day was beyond praise and everything was conducted throughout with a complete absence of hitch or delay. In the Senate House the only pauses in the proceedings were due to the vociferous cheering with which the undergraduates in the galleries, well supported by those below them, greeted the arrival of the Royal party at the head of a long procession of doctors of the university, and punctuated the addresses read by the Vice Chancellor and His Majesty's reply. In his first address the Vice-Chancellor referred to the faculty of medicine as having had from the earliest days of the University an honoured place in it and expressed the hope that it would now have a home worthy of its splendid progress in recent days, and King Edward in his reply, expressed his confidence that at Cambridge the progress thus referred to would be continued, adding, "to the older universities must succeed new endowments for education if my realm is to be kept up to its proper standard of efficiency."

After the conclusion of this portion of the proceedings the royal party drove to the Fitzwilliam Museum for luncheon, the Queen pausing before leaving the Senate House to shake hands with Sir William Broadbent who had been seated on the left of the platform near the two presidents. The royal party, with a few of the distinguished visitors and heads of colleges, were entertained at the Fitzwilliam Museum in the central picture gallery, and a large gathering at the same time enjoyed the hospitality of the Chancellor in the hall of King's College. When the Royal party after luncheon had driven to the doors of the medical school they were there received by Dr. T. Clifford Allbutt, Regius professor of physic, and Dr. G. Sims Woodhead, professor of pathology; Dr. J. B. Bradbury, Downing professor of medicine, being prevented by regrettable indisposition from attending to represent pharmacology. Professor Clifford Allbutt conducted the King and Queen with H.R.H. Princess Victoria to the Humphry Museum which they examined with interest and where Lady Humphry, the widow of the late professor of surgery after whom the museum is named, was presented to their Majesties. From the Humphry Museum the Royal party proceeded to the library where Professor Sims Woodhead did the honours, exhibiting the working of the sliding bookcases which he had chosen for their purpose after seeing similar ones used in the United States of America. A very small boy was intrusted with the demonstration of the ease with which several hundredweights of books can be made available in a moment and returned to occupy a fourth part of the wall space which they would fill in normal shelves. Specimens and illustrations connected with pathology had been arranged upon a table in the library of which their Majesties and Princess Victoria made a close examination, evincing particular interest in the specimens of trypanosoma nagana which Professor Sims Woodhead placed before them under a microscope and explained. After this, on His Majesty inquiring what more there might be for him to see in the building, Dr. W. E. Dixon exhibited some physiological experiments in the small pharmacological museum. So great, indeed, was the interest shown by their Majesties in what they saw and so long did they remain in the medical schools, that the crowd awaiting them in the courtyard of the buildings on the other side of the road to which they then proceeded had begun to wonder what could be detaining them. They were, however, able to complete their inspection of all with equal thoroughness. In the Botanical School, where they were received by Professor Ward, and in the Sedgwick Museum of Geology they saw and examined collections which in their present state demonstrated to all the need for new and ample buildings to contain them, and which, no doubt, will in course of time be largely increased. In the latter building the ceremonies of the day were brought to a fitting conclusion by the unveiling of the memorial statue of Professor Sedgwick, to the memory of whose character and life's work Professor Hughes paid eloquent tribute in an admirably delivered speech.

To Professor Clifford Allbutt, Professor Sims Woodhead, Professor Hughes, Professor Ward, and to all their colleagues who have worked long and earnestly in order to bring about those conditions in the University of which the splendid buildings now inaugurated are the outward manifestation, warm congratulations are due, and Cambridge will ever hold their names in honoured remembrance. Upon the success of a brilliant day to which their courteous grace and keen interest in all that was shown to them contributed in no small degree, we venture to congratulate our King and Queen, as well as upon the health and strength which enabled them to fulfil no slight task without apparent symptoms of effort or fatigue.

WORKMEN'S COMPENSATION ACT, 1897.

Sharman v. *Holliday and Greenwood, Limited.*

IN the Court of Appeal on Dec. 18th, 1903, an important decision was arrived at in regard to an appeal from a decision of the judge of the Lambeth county-court on an application under the Workmen's Compensation Act, 1897. The applicant was a workman named William Sharman who while in the employ of Messrs. Holliday and Greenwood had met with an accident arising out of, and in the course of, his employment, by which his leg was broken and he was for the time totally incapacitated for work. A memorandum of agreement was filed in the county-court by which the respondents agreed to make to the applicant a weekly payment of 15*s*. during his incapacity for work. Some time after the respondents applied to the county-court judge for a review of the weekly payment on the ground that the applicant's incapacity for work had ceased. At the hearing of that application medical evidence was called for both sides on the question whether the injury had or had not resulted in such a condition of the bones of the man's leg as to incapacitate him for work in future, and the county-court judge ultimately reduced the weekly payment to a nominal amount in accordance with the practice adopted in Pomphrey *v.* Southwark Press. In so deciding, he said, in substance, that the case was a very serious one, the question being really whether the applicant's claim was fraudulent or not; that the case was a difficult one but he thought that he was bound to come to the conclusion on the weight of the medical evidence that he should reduce the amount to the nominal sum of 1*d*. per week; but that the door was still open for the applicant to come again. Subsequently the applicant applied for a further review of the weekly payment on the ground that he had since the previous hearing sought work from several employers and been refused on the ground that he was not able to do it on account of the state of his leg, and also that on one occasion on which he had been able to get work he was subsequently discharged as being incapable of doing it on account of his condition. It was arranged that to save the expense of bringing further evidence, which possibly might be thrown away, the counsel for both parties should attend before the county-court judge in order that the applicant might formulate the grounds on which a further review was asked for and the judge might decide whether *primâ facie* they afforded any sufficient ground for reopening the case. At this preliminary hearing the counsel for the applicant stated that his grounds for asking for a review were: (1) the fact that the applicant had been refused employment repeatedly, even by his former masters, on account of the condition of his foot; (2) the fact that the county-court judge did not decide the case at the hearing solely on the medical evidence but partly on his personal observation of the applicant's movements, and that the highest expert medical evidence, on new observation and tests of the condition of the applicant, was now tendered to show that the applicant was unfit to follow his usual employment; (3) the fact that the learned judge kept the arbitration alive by awarding 1*d.* weekly in view of a change in the circumstances and that, the arbitration being so kept alive, it could not be *res judicata;* (4) the fact that the applicant did not seek for a fresh award but for a review of the weekly payment. The county-court judge held that, as he had decided on the previous occasion that the applicant's earning powers were not at that time diminished and as the present application was again on the ground of total incapacity the matter was *res judicata*, and that there was no evidence tendered of any change of circumstances since the previous hearing. He therefore dismissed the application.

After the case had been argued the Court of Appeal held that the doctrine of *res judicata* did not apply to the decision of the county-court judge on the previous hearing and that there apparently being evidence of a change of circumstances he ought to entertain the application. In the course of stating his opinion Lord Justice Mathew said that the position taken up by the respondents' counsel was that, although symptoms might develop after the original inquiry, which were clearly traceable to the accident but which were not before observed, nevertheless the doctrine of *res judicata* applied and there could be no further inquiry. He could see nothing in the Act itself which forbade further inquiry if after the original inquiry fresh symptoms developed or further incapacity for work was shown to have arisen. The expert witnesses on the side of an employer might be of opinion that, having regard to the symptoms then appearing, the condition of the workman was not such as to incapacitate him in future for work and the county-court judge might decide accordingly; but if the workman afterwards solved the question by experiment and on his endeavouring to obtain employment the result proved clearly that he was incapacitated there seemed to him (Lord Justice Mathew) to be no good reason why the county-court judge should be prevented from going into the matter again and reviewing the award. It would, in his opinion, be most unjust if in such a case the doctrine of *res judicata* should prevent the injured workman from applying for adequate compensation.

In accordance with the result of the appeal the case was tried again before Judge Emden in the Lambeth county-court on Feb. 26th.

In opening the case Mr. A. H. RUEGG, K.C., explained that he applied to the court under Clause 12 of the first schedule of the Workmen's Compensation Act, which said: "Any weekly payment may be reviewed at the request either of the employer or of the workman and on such review may be ended, diminished, or increased subject to the maximum." In August, 1901, the man Sharman was working for Holliday and Greenwood when a stack of timber fell upon him, breaking his left leg. The man was taken to St. Thomas's Hospital and it was ultimately found that the case was one of a serious and permanent injury. The employers, Messrs. Holliday and Greenwood, were liable for the accident and they were insured in an insurance company which recognised that it was a case of liability. They paid the man 15*s.* a week from August, 1901, till Jan. 21st, 1903, when the company applied at the Lambeth county-court to stop paying the money because in their opinion the case was a fraud and the man was shamming. The insurance company called as witnesses on their side Mr. T. D. Patmore and two other medical men. On the man's side Mr. Bernard Pitts was called but as Mr. Ruegg reminded Judge Emden he (the judge) said at that time that he was obliged to find upon the balance of the medical evidence that the man was shamming and that the injury from which he was apparently suffering was not a true injury at that time. Mr. Ruegg then went on to say that when that judgment was delivered there seemed to be a common mistake with regard to the question of the injury to the man's leg and with regard to the electrical reactions of the muscles of the leg. A test was applied in court by electricity and it was found that the muscles reacted normally and that on behalf of the insurance company was said to be a very important fact and it was supposed had some effect on the judgment delivered by Judge Emden. Mr. Ruegg said that he now had got evidence to lay before the judge that would satisfy him beyond all doubt that the electrical testing proved absolutely nothing in respect to the injury sustained by the man. The injury received was a mechanical one and it would be proved by skiagrams that a serious fracture at the ankle was caused by the accident in addition to the fracture of the tibia and fibula higher up.

The patient, WILLIAM SHARMAN, then gave evidence that after Jan. 21st, 1903, when his weekly allowance was reduced to one penny per week, he had sought to get work. A builder to whom he applied refused to give him a job because he was a cripple, a plasterer at Stockwell tried him for five hours and then discharged him, and several other employers of labour first tried him and then dismissed him on account of his leg.

The next witness was Mr. BERNARD PITTS, surgeon to St. Thomas's Hospital, who said that the injury received by the man had involved the bones of the ankle-joint with the result that the man was lame and permanently disabled. In answer to Judge Emden, Mr. Pitts explained that there was a fracture in two places, a fracture at the shaft and a fracture at the ankle. The fracture involving the ankle was attended with a displacement which caused lameness and which would continue to cause lameness. He repeated that he had pointed out before that the results of electrically testing the condition of the muscles could have nothing at all to do with the case and could not throw any light on it. In his opinion the disability of the man would increase with time rather than improve.

Mr. W. WATSON CHEYNE, surgeon to King's College Hospital, said that he had examined the patient and that he had clearly had a fracture in the neighbourhood of the ankle of both bones and it was known that he had had a fracture of the tibia and fibula higher up. The fracture of the ankle had caused a displacement of the foot and it was impossible for the man voluntarily to put the foot in the position it was in. In his opinion the man was not shamming and the injury would incapacitate him from the work of a labouring man for life. In reply to a question as to what he thought about the medical men who had examined the man's ankle most carefully and were ready to stake their reputation that there was no injury to the ankle at all Mr. Watson Cheyne simply said, "I am very sorry for them." He added that he was quite prepared to stake his reputation on the opinion he had expressed and explained that the patient had been taken to the Examination Hall, Victoria Embankment, for examination purposes and all the examiners had agreed as to the injury in regard to the case.

Mr. A. PEARCE GOULD, surgeon to the Middlesex Hospital, said that he had examined the patient and had come to the conclusion that there had been a fracture at the ankle-joint with a displacement of the foot. The man was lame by reason of the injury which was certain to be permanent and he could not believe that the man was an impostor. The man would always walk very slowly and was capable of only doing work that did not involve a steady balance and it had to be remembered that he would always walk with pain.

Mr. C. A. BALLANCE, assistant surgeon to St. Thomas's Hospital, said that he had examined the man's ankle and found that there had been a fracture of both bones of the leg in the neighbourhood of the ankle so that the foot was distorted. The inner border of the foot in standing and walking touched the ground in an abnormal manner. Pain would be caused if standing and walking were persisted in for any length of time. The man in his opinion was not shamming and would never be able to work.

Mr. E. C. STABB, surgeon to the Great Northern Central [illegible] Paddington Green Children's Hospital, said [illegible] and found consider- [illegible] by a fracture; the foot was displaced so that the inner border of the foot was lower than the outer. The man was perfectly unable to stand on his left foot alone.

to compel such persons to subject themselves to examination in Lincoln's-inn-fields. This Bill was, on various grounds, however, rejected by Parliament, and as it tended rather to benefit the College than the Profession, its fate is little to be regretted.

On the part of the Association a new Bill was prepared, the College of Physicians agreeing no longer to oppose its introduction into Parliament, provided the power of examining candidates were vested in the Apothecaries' Society.

In the year 1815, it was therefore permitted to receive the sanction of the legislature, and assume the force of law; those who look carefully into the Act will, I think, be of opinion with me, that it bears the marks of having been grievously maimed in its progress into the world; certainly the great body of General Practitioners were justly dissatisfied with several of its provisions.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8526 births and 5137 deaths were registered during the week ending Feb. 27th. The annual rate of mortality in these towns, which had been 17·2, 18·4, and 18·5 per 1000 in the three preceding weeks, declined again last week to 17·5 per 1000. In London the death-rate was 16·5 per 1000, while it averaged 18·0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·4 in Hornsey, 8·5 in East Ham, 9 6 in Handsworth (Staffs.), 10·2 in King's Norton, 10·8 in Tynemouth, 10·9 in Northampton, 11·8 in Willesden, 12·1 in Derby, and 12·2 in Walthamstow; the highest rates were 23·2 in Wigan, 23·7 in Stockport, 24·0 in Great Yarmouth, 24·2 in Halifax, 24·4 in Norwich, 25·1 in Merthyr Tydfil, 27·1 in St. Helens and in Warrington, and 30·6 in Plymouth. The 5137 deaths in these towns last week included 420 which were referred to the principal infectious diseases, against 412, 449, and 493 in the three preceding weeks; of these 420 deaths 163 resulted from whooping-cough, 104 from measles, 58 from diphtheria, 54 from diarrhœa, 22 from scarlet fever, 17 from "fever" (principally enteric), and two from small-pox. In Hornsey, Walthamstow, Reading, Devonport, Leicester, Huddersfield, and in 11 other smaller towns no death from any of the principal infectious diseases was registered, while they caused the highest death-rates in Great Yarmouth, Norwich, Birmingham, Warrington, Bury, Burnley, Rochdale, and West Hartlepool. The greatest proportional mortality from measles occurred in Great Yarmouth, Norwich, Aston Manor, Stockport, Warrington, Bury, Cardiff, and Rhondda; from scarlet fever in Walsall; from diphtheria in Hanley, Bootle, and Oldham; and from whooping-cough in Wolverhampton, Wigan, Warrington, Bolton, Rochdale, Burnley, West Hartlepool, Gateshead, Newport (Mon.), and Swansea. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the two fatal cases registered in these towns last week one belonged to London and one to Gateshead. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 25, 24, and 29 at the end of the three preceding weeks, had further risen to 31 at the end of last week; five new cases were admitted during the week, against eight, three, and nine in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital was 1587 on Saturday last, Feb. 27th, against 1657, 1644, and 1620 on the three preceding Saturdays; 150 new cases were admitted during the week, against 169, 162, and 143 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 347, 324, and 349 in the three preceding weeks, declined again to 322 last week, but were 51 above the number in the corresponding period of the preceding year. The causes of 78, or 1 5 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Leeds, Newcastle-on-Tyne, and in 40 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, St. Helens, Blackburn, Sheffield, Rotherham, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·5, 19·2, and 22·2 per 1000 in the three preceding weeks, declined again to 21·8 per 1000 during the week ending Feb. 27th, but was 4·3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·0 in Leith and 18·5 in Perth to 24·8 in Paisley and 26·2 in Greenock. The 720 deaths in these towns included 27 which were referred to measles, 21 to whooping-cough, 11 to diarrhœa, six to small-pox, six to "fever," five to diphtheria, and three to scarlet fever. In all, 79 deaths resulted from these principal infectious diseases last week, against 44, 72, and 75 in the three preceding weeks. These 79 deaths were equal to an annual rate of 2·4 per 1000, which was 1·0 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been seven, 21, and 19 in the three preceding weeks, rose again last week to 27, of which 19 occurred in Glasgow, four in Dundee, and four in Paisley. The deaths from whooping-cough, which had been 15, 24, and 26 in the three preceding weeks, declined again to 21 last week, and included six in Aberdeen, five in Glasgow, four in Leith, three in Edinburgh, and three in Dundee. The fatal cases of diarrhœa, which had been 11, 20, and 18 in the three preceding weeks, decreased again last week to 11, of which five were registered in Glasgow, two in Dundee, and two in Aberdeen. The deaths from small-pox, which had been three, one, and five in the three preceding weeks, further rose to six last week, and included four in Greenock and two in Glasgow. The fatal cases of "fever," which had been two, one, and one in the three preceding weeks, increased again last week to six, of which three occurred in Glasgow. The deaths from diphtheria, which had been three, three, and six in the three preceding weeks, declined again to five last week, and included two in Dundee. Of the three fatal cases of scarlet fever two were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 129, 126, and 167 in the three preceding weeks, declined again last week to 165, but were 73 in excess of the number in the corresponding period of last year. The causes of 33, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·5, 27·2, and 29·7 per 1000 in the three preceding weeks, declined again to 27·2 per 1000 during the week ending Feb. 27th. During the past four weeks the death-rate has averaged 28·7 per 1000, the rates during the same period being 17·4 in London and 17·6 in Edinburgh. The 198 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 18 from the number in the preceding week and included 15 which were referred to the principal infectious diseases, against 12, ten, and 16 in the three preceding weeks; of these, 11 resulted from whooping-cough, two from measles, and two from "fever," but not any from small-pox, scarlet fever, diphtheria, or diarrhœa. These 15 deaths were equal to an annual rate of 2·1 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 0·8 in Edinburgh. The fatal cases of whooping-cough, which had been nine, six, and nine in the three preceding weeks, further rose last week to 11. The 198 deaths in Dublin last week included 38 of children under one year of age and 58 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Four inquest cases and three deaths from violence were registered, and 65, or nearly a third, of the deaths occurred in public institutions. The causes of nine, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon: E. R. D. Fasken to the *Æolus*. Staff Surgeon: E. Corcoran to be Staff Surgeon in charge of Royal Naval Hospital, Portsmouth. Surgeons: *W. L. Martin to the Moorhen* on recommissioning; G. O. Cross to the *Teale*; O. H Dawe to the *Snipe*; G. D. Bateman to the *Tamar*; and C. T. Baxter to the *Alert*.

Deputy Inspector-General of Hospitals and Fleets Herbert Mackay Ellis has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Feb. 18th, 1904).

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Thomas Dufour Halahan and Percy Hamilton Boyden (dated Nov. 14th, 1901); Norman Ireland Smith and Shirley Hall Birt (dated May 16th, 1902); and William Reynolds Trythall (dated Nov. 12th, 1903).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are confirmed in that rank:—W. F. Ellis, F. W. W. Dawson, J. H. Duguid, G. W. G. Hughes, A. O. H. Gray, D. P. Watson, T. S. Dudding, J. E. Powell, F. M. M. Ommanney, O. Ievers, R. H. MacNicol, H. H. J. Fawcett, S. L. Pallant, N. DE. Harvey, C. R. Bradley, S. E. Lewis, G. A. Kempthorne, J. T. McEntire, F. M. G. Tulloch, P. J. Hanafin, J. D. Richmond, E. M. Glanvill, M. C. Wetherell, H. O. Hildreth, G. S. Mackay, W. MacD. MacDowall, and R. T. Collins.

Major H. S. Peeke has joined at Aldershot for duty and has taken over the medical charge of the Cavalry Brigade. Captain G. Dansey-Browning has joined the Aldershot Command and been posted to the Princess Louise Hospital at Alton for duty. Lieutenants R. L. V. Foster and G. W. Smith proceed for Bombay shortly. The following officers have been posted for duty: Lieutenant O. Ievers, Lieutenant R. H. MacNicol, Lieutenant J. T. McEntire, Lieutenant N. DE. Harvey, and Lieutenant P. J. Hanafin to the Curragh. Lieutenant A. O. Osburn and Lieutenant F. M. Tullock to join the Medical College, London. Lieutenant D. P. Watson, Lieutenant S. L. Pallant, Lieutenant M. C. Wetherell, Lieutenant T. S. Dudding, Lieutenant C. R Bradley, Lieutenant H. H. J. Fawcett, Lieutenant R. T. Collins, and Lieutenant G. S. Mackay at Netley.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement from the service of the undermentioned officer: Lieutenant-Colonel Walter Peter Carson (dated Jan. 28th, 1904).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant A. A. MacKeith, 1st Hampshire Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant (dated Feb. 27th, 1904).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Buffs (East Kent Regiment: Surgeon-Captain A. E Larking resigns his commission (dated Feb. 27th, 1904). 4th (Hunts) Volunteer Battalion the Bedfordshire Regiment: The undermentioned Surgeon-Lieutenants to be Surgeon Captains: E. J. Cross (dated Feb. 27th, 1904) and W. F. Fisher (dated Feb. 27th, 1904). 1st Volunteer Battalion the Lancashire Fusiliers: The undermentioned Surgeon-Captains to be borne as Supernumerary whilst doing duty with the Lancashire Fusiliers Volunteer Infantry Brigade Bearer Company: R. Mitchell (dated Feb. 27th, 1904); A. P. Nuttall (dated Feb. 27th, 1904); and J. W. Cook (dated Feb. 27th, 1904).

THE REMOVAL OF WOUNDED SOLDIERS FROM THE FIELD OF BATTLE.

In the land battles of the future it is unfortunately only too probable that the tale of wounded men will be enormous. The cases requiring medical assistance will be so numerous that the means of transport ordinarily at the disposal of the medical authorities will prove to be totally insufficient. So much depends on the precautional measures adopted when a wounded man is lifted from the spot where he has fallen in order to be conveyed to a place where his injuries can be investigated and adequately attended to that every effort should be made in time of peace to organise a system whereby a sufficiency of trained men may become available without any delay when emergencies arise. Four bearers are required to carry a wounded soldier off the field of battle if the distance is considerable and of these one at least should be a trained man. It is not at all likely, however, that during and after a severe engagement there would be a sufficient number of trained men on the spot and the possibility must also be contemplated that the number of stretchers may also be deficient. *Cases of this description can be treated in three* ways: (1) the wounded men may be left unattended for a time—a most undesirable thing; (2) they may be removed

late number of the *Deutsche Militarärztliche Zeitschrift* Dr. Jerzabek strongly advocates the last named view, which he maintains is by no means so unreasonable as might at first sight be supposed. The expenditure of time would be inconsiderable because stretcher instruction could be combined with that at present given in the application of the dressing material which all soldiers carry. Every recruit could be taught the manipulation of the regulation stretcher, but this is not absolutely essential because wherever trained bearers were insufficient there would probably be a deficiency of regulation stretchers also. If time were an object this portion of the course could be dispensed with and it would not be necessary to burden the recruit's memory with details of the various methods for improvising stretchers out of sacks, tentcloth, overcoats, &c., with which many manuals are overloaded. One particular form of appliance for use in an emergency should be selected and every man should be thoroughly taught how to manipulate it. The appliance which Dr. Jerzabek considers most suitable for the purpose is one which has been employed, he says, with great success by French, Dutch, and English colonial forces. It consists of a rod (bamboo for choice) from ten to 12 feet long and capable of supporting in the horizontal position a weight of 330 pounds, a piece of light canvas ten feet by four, and some fine but strong cord. The canvas rolled from each end till the rolls almost meet should be turned upside down and slipped sideways beneath the wounded man's buttocks. The rolls should then be gently unrolled under him, leaving something more than two feet free at his head and his feet respectively. These projecting portions should be re-rolled inversely as far as may be convenient and then bent upwards till their ends overlap each other. In this position they should be firmly tied, forming a ring through which the rod is to be passed. Should an injured limb require support a sling can be passed under it and the ends made fast to the pole. On arrival at the dressing station the canvas freed from its cords can be made to serve as a sheet if necessary. The appliance is most portable and very light. A great number of them could be carried up to the fighting line in an empty regulation stretcher.

ARMY REFORM: SECOND REPORT OF LORD ESHER'S COMMITTEE.

The War Office Reconstruction Committee has issued the second part of its report; the third is shortly to follow and the scheme will then be complete, when it can be fully *considered* with a view to a more satisfactory and definite judgment being given in regard to it as a whole. Meanwhile there are certain points which cannot escape attention. To begin with, the enormous amount of labour involved in designing and drawing up a scheme of this kind and the rapidity with which the work is being done are something remarkable. The task which the committee—composed of Lord Esher, Admiral Sir J. Fisher, and Lieutenant-Colonel Sir G. Clarke—had to undertake was of the most difficult and intricate kind, demanding power of organisation and constructive ability as well as directness of aim and intellectual courage for its solution. The reforms proposed in Part II. are as drastic as those previously set forth. The newly issued report is prefaced by a letter addressed to the Prime Minister by the committee in which it is stated that "His Majesty's Government have already approved of the whole of Part I., and we strongly urge the acceptance of the proposals now laid before you in Part II. in order that they may forthwith be put

Part III of our report, which deals with

es of the War Office other

aff, with the position of the

other matters of importance,

ission. We desire it to be

clearly understood that our scheme of reform has been conceived and elaborated as a whole and that any interference with the principles on which it is based would necessarily destroy its benefits. With the completion of Part III. our mission will have been fulfilled." In Section IV. of Part II. dealing with "the chief of the general staff" we find the following remarks: "There is at the present time a great lack of information as regards technical military progress in other countries. An officer of Royal Artillery and of the Royal Army Medical Corps should therefore be attached to the section of the director of military operations which deals with intelligence. It should be the duty of these officers to supply the branch of the master-general of the Ordnance and the director-general of the Army Medical Services with information in regard to new developments of armaments or of military hygiene and these officers should be enabled to travel for this purpose when necessary." If the boldest course in certain circumstances is the best no fault can be found with the committee's reports in this respect. We may assume that in a general way our readers are acquainted with the sweeping and wholesale changes proposed by the committee which, if carried out, will be almost tantamount to having a new army, a new War Office, and a new army system. As regards the Army Medical Service, we shall be better able to speak after the House of Commons has had an opportunity of expressing an opinion on the new army scheme and when the third and last part of the committee's report has been published.

THE ARMY ESTIMATES.

We gather from the Army Estimates for 1904-05 that the total number of men to be voted is 227,000 and shows a decrease of 8761, as compared with the numbers voted for 1903-04 Of this decrease 4200 are due to the increased garrison of South Africa being found in 1904-05 within the ordinary establishments, instead of being provided for by a vote of temporary additional numbers, as in 1903-04. The balance of 4561 is due to decreases in other corps. On the other hand, there are small increases in the Royal Army Medical Corps and the Army Pay Corps. The estimate for the Royal Army Medical Corps is for a strength of 4648 for the coming and present financial year as compared with 4154 in 1903-04. The figures for the Army Medical Staff (including Headquarters Staff) and medical officers not included under the Royal Army Medical Corps remain the same. The estimated cost of the medical establishment for pay, &c., for the present financial year is £484,000, as against £530,000 for the past year—a decrease of £46,000. The establishment of British regiments of all ranks serving in India gives an estimated total of 74,657, which includes 337 Royal Army Medical Corps.

THE HEALTH OF THE ROYAL NAVY.

The statistical report of the health of the Royal Navy for the year 1902 has just been issued in the form of a blue-book. The returns for the total force serving afloat in the year under notice, the report states, may be considered satisfactory. With a *personnel* increased by 1190 as compared with the previous year there is an increase in cases and deaths but a decrease in invalidings. The numbers are respectively 85,769, 590, and 2985, in comparison with 84,026, 526, and 3108 in 1901. The aggregate number of cases of disease and injury recorded during the year furnishes a ratio of 861·13 per 1000, which shows an increase of 7·3 per 1000 as compared with the ratio for 1901, but a decrease of 22·2 when contrasted with the average of the last five years. The prevalence of, and mortality from, enteric fever show a slight decrease; one case of plague is recorded and there were five cases of cholera, with four deaths. A decline in the ratio of cases of primary syphilis is shown but increases are shown as regards constitutional syphilis and gonorrhœa. Two cases of wounds in action are recorded, with one death.

THE NEW INSPECTOR-GENERAL.

It is officially announced that with the approval of the King H R H. the Duke of Connaught and Strathearn has been appointed as the new Inspector-General of the Forces and President of the Selection Board.

We understand that arrangements are in progress for extending in the Army a system of training for increasing the visual powers of soldiers and developing their powers of observation in the field.

Brevet Colonel D. Bruce, R.A.M.C., has been specially selected for increased pay under Art. 365 of the Pay Warrant.

Obituary.

SIR EDWARD HENRY SIEVEKING, M.D. EDIN., F.R.C.P. LOND.,

PHYSICIAN-IN-ORDINARY TO THE LATE QUEEN VICTORIA; PHYSICIAN EXTRAORDINARY TO THE KING; PHYSICIAN TO THE LATE DUKE OF CAMBRIDGE; CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE LOCK HOSPITAL.

As we briefly announced last week Sir Edward Henry Sieveking died on Feb. 24th at his house in Manchester-square. The medical profession of this country has thereby lost one of its best known members who for more than 50 years enjoyed a distinguished position not only as a physician in the scientific sense but as the trusted medical adviser of the highest personages of the State.

Sir Edward Sieveking, who at the time of his death had attained the advanced age of 87 years, was born in St. Helen's-place, Bishopsgate, in the City of London, on August 24th, 1816. For an outline of his lineage and youthful journeyings on the continent we are indebted to some autobiographical memoranda which have been intrusted to us by his youngest son Mr. A. Forbes Sieveking, and which we hope may eventually be given to the public in an extended form. Sieveking was descended from an ancient Westphalian or North German Lutheran family. It is suggested that the original spelling of the name was Sieviking, a name which marked descent from the Vikings, the Scandinavian adventurers who settled in Westphalia in the eleventh century. Anyhow, the family dates back to the sixteenth century and subsequently became prominent in the intellectual, political, and mercantile circles of Hamburg. In the early part of last century, for instance, an uncle was known among European statesmen in connexion with the negotiation of commercial treaties. Sieveking's parents came from Hamburg and settled in London in 1809, his father becoming a merchant in Fenchurch-street. His mother was a daughter of Senator J. V. Meyer of Hamburg. His education was commenced in England and continued on the continent, first at the Gymnasium of Ratzeburg (about the time when Samuel Taylor Coleridge was writing some of his best known letters from the lake-girt island near Lübeck in Mecklenburg-Strelitz) and then at the Gymnasium of Berlin. Of his stay at the latter school and his subsequent movements he has left a record as follows: "I passed the *Abiturienten-Examen*, obtained a certificate of 'maturity,' and transferred my allegiance to the Berlin University, where I dissected under Schiemann, attended the lectures on physiology by Johannes Müller and those on chemistry under Mitscherlich, and then went to Bonn for a year where I attended lectures on surgery and made myself well acquainted with the Rhine and its lovely tributaries. ...... For two years I studied medicine at University College, London, and then went to Edinburgh University where I graduated as M.D. in 1841, my thesis on 'Erysipelas' receiving a star of distinction. In the latter part of 1841 I went to Paris for the winter and studied at the Hôtel Dieu under Andral, at the Hôpital St. Louis (for skin diseases), and the Hôpital du Midi, where I followed the practice and teaching of Ricord, ... travelled through France and North Italy to Vienna, where Jager especially attracted me, and I attended a private course of ophthalmic surgery under his assistant Rigl, when I travelled with my parents through Hungary, Tyrol, and South Germany." After his *wanderjahre* he practised for a short time, about four years, amongst the English colony in Hamburg, where he delivered a course of lectures and founded a children's hospital in conjunction with his aunt, Miss Amalia Sieveking, a philanthropist and pioneer of nursing, whose biography, translated by Miss Caroline Winkworth, is still known in England. He also published in German a treatise on Ventilation and started the Alster Rowing Club, which athletic association delighted later in honouring their founder.

It will be seen that his early education was calculated to give him self-reliance and a sound introduction to medicine as well as to make it unlikely for him to take narrow or prejudiced views. Returning to London in 1846 he commenced medical practice in Bentinck-street, Manchester-square, where he resided until 1857, when he removed to Manchester-square, living there until the day of his

SIR EDWARD H. SIEVEKING, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN EXTRAORDINARY TO HIS MAJESTY THE KING.

death. He was admitted a Member of the Royal College of Physicians of London in 1847 and soon engaged actively in literary work. In 1849 he published a small treatise with the title, "The Training Institutions for Nurses and the Workhouses," a question in which he felt much interest and which also formed the subject of a paper read by him before the Epidemiological Society in 1854. In the same year he translated for the Sydenham Society Vol. II. of Rokitansky's "Pathological Anatomy." After holding the post of physician to the Northern Dispensary he was appointed in 1851 assistant physician to St. Mary's Hospital, an institution with which he maintained a life long connexion. At an early period he became lecturer on materia medica and for 37 years in the wards, the class-room, and the out-patient department he was a prominent figure in the school. He became full physician to the hospital in 1860, only retiring from this position in 1888, when he was placed on the consulting staff. He was also one of the first physicians appointed to the staff. In 1852 he was elected a Fellow of the Royal College of Physicians of London and afterwards filled various offices in the College, including those of examiner, Harveian orator, senior censor, and vice-president. As vice president under Sir William Jenner his claim to the presidency was held by many to be stronger than that of Sir Andrew Clark, but Sir Edward Sieveking himself, after experience of Clark's strenuous ways, allowed that he had been superseded by a man with peculiar aptitude for the post. In 1866 he delivered the Croonian lectures in the College, the subject of them being the Localisation of Disease. In 1877 he delivered the Harveian oration, with the result that the College, together with the Royal College of Surgeons of England, aided him in producing an autotype publication of the MS. of Harvey's original physiological lecture delivered in 1616.

At an early stage of his career he contributed to the *British and Foreign Medico Chirurgical Review*, then edited by its founder, Sir John Forbes, who became his firm friend and whose name was given to Sieveking's youngest son in 1857, the year in which Sieveking succeeded to the editorship of the *Review*. In addition to Sir John Forbes and his colleagues at the hospital and the Royal College of Physicians of London, he was on terms of intimate friendship with many men eminent in medicine and literature, including Sir David Brewster, Charles Kingsley, F. D. Maurice, and Henry Crabb Robinson, who knew his parents and in whose reminiscences will be found a eulogistic allusion to the son. Sir Edward Sieveking's first contribution to THE LANCET appeared in the issue of Sept. 10th, 1853, and was entitled "A Case in which Hydatids were Discharged from the Kidney during Life" In 1854 with the collaboration of Dr. Handfield Jones (also of St. Mary's Hospital), he published a "Manual of Pathological Anatomy." In 1858 there appeared the first edition of his important work on "Epilepsy and Epileptiform Seizures, [illegible] ent," which was reviewed [illegible] that year. In 1861 he [illegible]. Remarks on Neuralgia in a series of five articles and also became president of the Harveian Society. Many years previously he had been appointed physician-in-ordinary to the late Duke of Cambridge, the father of the present Duke. In 1863, on the recommendation of Sir James Clark, he was appointed physician-in ordinary to the Prince of Wales, now the King. In 1873 he was made physician extraordinary and in 1888 physician-in-ordinary to her late Majesty Queen Victoria, having been knighted two years earlier.

In 1849 he married Miss Jane Ray who survives him. By her he had five sons, one of whom is in the medical profession, and three daughters, one of whom is now the wife of Professor Starling, having previously been married to the late D·. L. Woolridge.

The following appreciation of Sir Edward Sieveking's work as a colleague comes from a member of the staff of St. Mary's Hospital, and shows well the esteem which he enjoyed among his colleagues as physician, teacher, and friend: "It is some years since Sir Edward Sieveking took an active part in the practice of medicine, but those who had the pleasure of his intimate acquaintance will remember him as one who, if still imbued with many of the traditions of an earlier school of thought and action, was keenly impressionable to the influence of more recent methods. He was in the exact sense of the term a general physician and considered specialism in its narrower interpretation with little tolerance. A survey of his professional career reveals the wide range of his intellectual activity. Whatever subject he touched—e g., pathology, neurology, climatology—he left the record richer by his work and pen. He possessed much of the courtly grace exemplified by many of his contemporaries and successfully strove to maintain the lofty ideal he had always in view. Whilst appreciative of the claims of others he knew how to assert his settled convictions. What Lord Granville was in politics Sieveking was in medical polemics. If he excelled in one thing more than another it was in the rational treatment of disease, and whilst paying primary attention to the special nature of an ailment he never neglected the claims of the body corporate. He made humanity his study and the amelioration of its ills his constant care. 'He had a tear for pity and a heart open as day for melting charity.' As a colleague he was loyal and devoted. To his equals in station he was deferential; to his subordinates he was encouraging, helpful, and considerate. His methods of teaching were not, perhaps, quite in accordance with the present trend of directive as opposed to descriptive inculcation of knowledge, but he was clear in diction, impressive in manner, and conclusive in argument. The medical profession has lost one of its most honoured lights and St. Mary's Hospital, the home of his life-work, a guide, counsellor, and friend"

This brief appreciation of his work at St. Mary's Hospital depicts Sir Edward Sieveking graphically. We see how the liberal education and varied opportunities of his youth gave flexibility to his views and breadth to his sympathies and we can understand that when once he was interested in a subject he spared no pains in promoting the views upon it which he thought sound. To questions of nursing, education, and hygiene he paid the close attention which he considered such matters should exact from the general physician with the result that he was able to give well-reasoned advice in directions where many medical men would have considered ignorance excusable. And with all his wide range of accomplishments a high ideal of conduct kept him courteous, generous, and kind. Though in a sense Sir Edward Sieveking belonged to a day that is past his death is deeply felt by the medical profession.

The funeral took place on Feb. 27th at Abney Park Cemetery, the memorial service being held in St. Thomas's Church, Orchard-street, Portman-square.

A. A. LIEBEAULT, M.D.

Dr. Liébeault, who died at Nancy on Feb. 18th, was the *doyen* of the Nancy School of Hypnotism. Born in 1823 he studied medicine at the University of Strasburg where he took his M.D degree. After a few years spent in general practice in the country he settled in Nancy, where he established a clinique for the free treatment of the poor by a system which came to be known as treatment by suggestion. In 1866 he published his first book on the subject, "Sommeil et les États Analogues," which, however, met with a very poor reception. Nevertheless, Dr. Liébeault continued to work with enthusiasm and success and in 1881 he obtained the support of three eminent professors in the university—Bernheim, Beaunis, and Liégeois. Thus arose the Nancy school which has done so much to establish the practice of hypnotism on a scientific basis. Dr. Liébeault when he retired on a modest competence in 1890 was the recipient of a testimonial of remarkably cosmopolitan character from about 60 medical friends and pupils, referred to in THE LANCET of that year. His kindly and unassuming disposition endeared him to all who met him, and the widespread influence of his teaching is a pleasing testimony to the success of perseverance and singleness of purpose.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. José Calvo y Martin, formerly professor of anatomy in Madrid and Senator of Spain.—Dr. Juan J. Flores, formerly Minister of the Interior in the Republic of Costa Rica and at one time Dean of the Faculty of Medicine, San José.—Dr. Alexander Spiess of Frankfort, editor of the *Deutsche Vierteljahrsschrift für offentliche Gesundheitspflege.* His son, Dr. Gustav Spiess, has been in attendance on the German Emperor during his laryngeal trouble.

Correspondence.

"Audi alteram partem."

DR. SCHMIDT'S TREATMENT OF CANCER.

To the Editors of The Lancet.

Sirs,—We beg to forward you a copy of a letter that we have received from Dr. H. Jossé Johnson who has been afforded facilities since Nov. 26th, 1903, of trying Dr. Otto Schmidt's treatment upon cancer patients in the Middlesex Hospital. The treatment was tried upon the following nine cases.

Case 1.—A female, aged 56 years; cancer of the cervical glands; ten injections; maximum dose 2 centigrammes; death.

Case 2.—A female, aged 50 years; mammary cancer; ten injections; maximum dose 1·5 centigrammes; death.

Case 3.—A female, aged 71 years; mammary cancer; 11 injections; maximum dose 2·5 centigrammes. Alive at the present time.

Case 4.—A female, aged 73 years; mammary cancer; 11 injections; maximum dose 3 centigrammes. Alive at the present date.

Case 5.—A female, aged 56 years; double mammary cancer; ten injections; maximum dose 3 centigrammes. Alive at the present date.

Case 6.—A male, aged 60 years; cancer of the rectum; 35 injections; maximum dose 2 centigrammes. Alive at the present date.

Case 7.—A male, aged 51 years; sarcoma of the neck; nine injections; maximum dose 9 5 milligrammes; injections discontinued on account of illness of the patient; death.

Case 8.—A female, aged 43 years; mammary cancer, recurrent; six injections; maximum dose 2 centigrammes. Alive at the present date.

Case 9.—A female, aged 37 years; operable supraclavicular gland; infected from a cancer of the breast that had previously been removed. The gland was subsequently removed. Seven injections; maximum dose 2 centigrammes. Alive at the present date.

(Cases 8 and 9 underwent a rapid exaltation of dose in order to test the alleged diagnostic value of the injections.)

On Nov. 28th Dr. Schmidt visited the hospital and saw all the patients except Nos. 6 8, and 9, who were not then under treatment. He expressed himself as satisfied with all the cases (except No. 7) as being suitable for test purposes.

We have failed to observe any trace of a specific local or general reaction to the injections and we are therefore convinced that the material is entirely without diagnostic value. We have equally failed to see any local or general improvement in the condition of a patient. The injections in no wise alter the course of the disease. In the case of those patients who died microscopical examination of the tissues failed to reveal any differences in appearance from those usually met with in cases that have not undergone the special treatment. The material used was sent direct from Dr. Schmidt's laboratory to Dr. Johnson and Dr. Johnson made all the injections himself except on two occasions. The material used was Dr. Schmidt's "killed culture" A full account of the research will be published later in the Archives of the Middlesex Hospital.

We are, Sirs, yours faithfully,
Henry Morris,
Chairman of the Cancer Investigation Committee;
Andrew Clark,
A Pearce Gould,
W. Pasteur,
Members of the Cancer Investigation Committee;
W. S. Lazarus Barlow,
Director of the Cancer Research Laboratories.
Middlesex Hospital, Feb. 24th, 1904.

[Inclosure]

Copy of Dr. Jossé Johnson's letter.

29, Gracechurch-street, E C.
Feb 4th, 1904.

To the Cancer Committee,
Middlesex Hospital.

Gentlemen,—I beg to thank you sincerely for granting me opportunity to test the value of Dr. Otto Schmidt's treatment of cancer in your hospital.

That the experiments carried out by me under Dr. Barlow's kind and courteous supervision have failed to demonstrate the results I had described does not in any way lessen my obligation and thanks.

Believe me, Gentlemen, yours faithfully,
(Signed) H. Jossé Johnson.

CONTINUOUS CLINICAL TEMPERATURE CHARTS.

To the Editors of The Lancet.

Sirs,—I have read with much interest in The Lancet of Feb. 27th, p. 585, the account given by Professor Ronald Ross of continuous clinical temperature charts. Shortly before his death the late Professor Roy was exercising his mind in this same direction and I, who was then working as a student in the Pathological Laboratory at Cambridge, was very kindly taken into his confidence in the matter and had the advantage of considerable conversation with him on the subject. I believe I am right in saying that at this time the Callendar electric recorder was a recent invention and the views alluded to below were in connexion with the capabilities liberated by it. Professor Roy's opinion was that the result to be aimed at was the obtaining of a record of the amount of heat given out by the body rather than a mere record of the temperature of any particular part. And he even then was suggesting a clinical application and sketched out the abolition of bedclothes and the substitution of a cage-rigged covering, through which the variations of loss, as effected by changes of room temperature or other causes, could be approximately ascertained.

Professor Roy thought that a continuous record of the air temperature underneath the covering might be a useful practical index to the amount of heat being given out by the body. He said that the ascertaining of the temperature of any particular part would be of much value when considered in connexion with the amount of heat being given out by the whole body at the time. The shortcomings and imperfections of even well-kept temperature charts as they are now compiled are many and serious. I have on several occasions sketched out what from time to time suggested itself to my mind as a worthy experimental apparatus but have never as yet had the courage to face practical trial.

I am, Sirs, yours faithfully,
Cheltenham, Feb 29th, 1904. Edgar G. Trevithick.

NELSON AS A PATIENT.

To the Editors of The Lancet.

Sirs,—To The Lancet of July 24th, 1897, p. 195, Mr. Edmund Owen communicated an interesting article entitled "Nelson as a Patient," and referring to the alleged "clumsiness" of the surgeon on board the *Theseus* in including the median nerve in the ligature on the brachial artery he speaks sympathetically of the difficulty of attaining surgical accuracy in the performance of operations between-decks 100 years ago. It is clear that Mr. Owen adopts the generally accepted belief in the inclusion of the nerve but the question may well be asked as to the grounds for this belief. The arm was amputated on July 25th, 1797, the day after the unsuccessful attack on Santa Cruz de Teneriffe, Nelson landed in England on Sept. 1st, proceeded to Bath, and thence to lodgings in Bond-street, London, where a consultation was held as to whether anything could be done for the relief of severe neuralgic pain connected with the stump. Nothing operative was attempted and the ligature came away in the latter part of November. On Oct. 2nd Nelson wrote from his Bond-street lodgings the letter of which Mr. Owen gave a facsimile copy, in which reference is made (for the first time so far as I can gather) to the "unlucky circumstance" of the inclusion of the nerve in the ligature. "My arm from the unlucky circumstance of a nerve being taken up with the artery is not yet healed nor do I see any prospect of the ligatures soon coming away." Two years later he wrote of it to Clarke and McArthur as "an unlucky mismanagement." The obvious conclusion to be drawn is that the inclusion of the nerve was suggested to Nelson by the London surgeons as a possible, if not probable, cause of the neuralgic pain from which he suffered.

Surely no such explanation was necessary. Every surgeon must be aware of the frequent occurrence of neuralgic pains referred to the extremities of a limb amputated weeks or months previously when there has been no possibility of the inclusion of a large nerve in a ligature. The advancement of this theory made the work of the literary man easy.

"His sufferings from the lost limb were long and painful. A nerve had been taken up in one of the ligatures at the time of the operation and the ligature, according to the practice of the French surgeons, was of silk instead of waxed thread; this produced a constant irritation and discharge and the ends of the ligature being pulled every day in hopes of bringing it away occasioned fresh agony. He had scarcely any intermission of pain, day or night, for three months after his return to England. Lady Nelson at his earnest request attended the dressing of his arm till she had acquired sufficient resolution and skill to dress it herself. About the end of November, after a night of sound sleep, he found the arm nearly free from pain. The surgeon was immediately sent for to examine it and the ligature came away with the slightest touch; from this time it began to heal."

to the lay mind, that the alleged would have become gangrenous at the point of constriction a few hours after its application four months previously, would be followed by the immediate relief of pain On such insufficient evidence was the poor surgeon of the *Theseus* publicly, if not privately, condemned, his career probably blighted, and his surgery stigmatised as clumsy and awkward by every biographer of Nelson from Clarke and McArthur down to Captain Mahan. Is it not possible to explain Nelson's condition during these four months without blaming the surgeon for an error which has never been proved against him? Nelson's nervous system was always highly strung and over-sensitive. Two days after he lost his arm he wrote to Sir John Jervis saying that he was become a burden to his friends and useless to his country—"I become dead to the world and am no more seen"—and asking the Admiral for a frigate to convey "the remains of my carcass to England." This extreme mental depression would without doubt intensify the neuralgia of the stump so frequently experienced after amputation and he would also suffer, as Mr. Owen pointed out, from the absorption of small doses of septic discharge from the walls of the sinus which would naturally make him ill and irritable. By the end of August, moreover, the knotted loop of the ligature would be lying loose in the cul-de-sac at the bottom of the sinus imbedded in a mass of granulation tissue, the artery would be well retracted up amongst the muscles, and its lumen obliterated by organised clot up to the collateral circulation. The cut median nerve, on the other hand, being non retractile, would still have its cicatrising, bulbous end in close proximity to the knotted loop which might possibly be a source of irritation to it. Be that as it may, the removal of the ligature would put an end to his ill-health and the bad effects produced by restless chafing against the delay of convalescence. Life would become bearable again—any remaining neuralgia of the stump could be borne with equanimity. "Richard was himself again" and fit for duty, so we find him on Dec 8th sending the following form of thanksgiving to the minister of St. George's, Hanover square: "An officer desires to return thanks to Almighty God for his perfect recovery from a severe wound and also for the many mercies bestowed on him." On Dec 19th he was appointed to the command of the *Vanguard*.—I am, Sirs, yours faithfully,

Epworth, Feb. 24th, 1904. A. F. MESSITER.

RAYS PROCEEDING FROM ACTIVE MUSCLES AND NERVES.

To the Editors of THE LANCET.

SIRS,—With reference to the communication on this subject from Dr. Hugh Walsham and Mr Leslie Miller, which appears in THE LANCET of Feb. 27th, p. 610, and with reference also to your editorial notes thereon, I should like to be allowed to say that during the past few weeks I have spent much time in endeavouring to confirm the experiments of M. Blondlot and also of M Charpentier, and have published the results of my investigations in the columns of *Nature* and of the *Electrician*. It is by no means difficult to get some of the effects that M Blondlot and M Charpentier and also your correspondents describe, but so far as my observations go, these effects. when obtained, are in every case due simply to heat and require no new description of rays for their explanation. The luminosity of calcium sulphide, as also of most other phosphorescent substances, is considerably affected by minute differences of temperature; for instance, a coin taken from one's pocket and held at the back of a calcium sulphide screen will, by reason of its warmth, show through the screen as a disc of increased luminosity in a few seconds. Again, if two small screens covered with this material are placed upon two similar bodies, differing in temperature by only 2° F., it is easy to discover which of the two bodies is the warmer by the superior luminosity of the screen placed upon it. Again, the mere warmth of the breath is quite sufficient materially to increase the brightness of a suitable phosphorescent screen.

Difference of temperature is, I believe, the explanation of the "foot" experiment described by your correspondents. I have repeated this experiment with entire success and I must confess that at first sight it seems most convincing. My method is to use two very small calcium sulphide screens each about 16 millimetres by two millimetres in size and of normally equal brightness. Both are placed upon the floor and give an equal amount of luminosity; then one is placed on the foot and is found to brighten up considerably as compared with the other. Unfortunately, however, for the "n" ray theory I find no necessity for the presence of the foot at all, nor do we require active muscles or nerves to produce the effect. A boot newly taken off and still retaining some warmth, or any other warm object, acts equally well, while if one screen be placed on the foot and the other upon a can of water heated to the same temperature as the foot no difference can be detected between the luminosity of the two screens. Again, the "foot" experiment does not succeed if a good thickness of paper or cardboard is placed between the foot and the screen so as to prevent the transference of warmth to the latter.

I have described my observations with regard to this "foot" experiment at some length as your correspondents describe it as "one of the most convincing tests," but my conclusions are similar—i e, that the effects are simply due to heat, with regard to other parts of the body. I am quite ready to believe that certain parts of the body and certain muscles and nerves in a state of activity may possibly be more efficient than others in producing extra luminosity in the screen. I have not been able to observe this myself, but assuming that it is so I would suggest that local differences of temperature and of heat radiation will account for these effects without having recourse to recondite theories and to new descriptions of rays.

I note that your correspondents think it necessary to give a word of caution as to the effects of heat and state that they have confirmed some of M. Charpentier's experiments whereby he claims to have proved that the effects he has noted are not due to heat only. It would be interesting to learn exactly what these experiments that your correspondents have confirmed actually are. I have not personally tried M Charpentier's "frog" experiment and can therefore give no opinion in regard to it. As mentioned above, however, I have found, contrary to his observations, that layers of cardboard forming a heat screen do interfere with the effect. Again it does not seem to me that M. Charpentier's experiment wherein he raised the screen to a greater temperature than the animal experimented with is in any way conclusive as the proximity of any body, the temperature of which exceeded that of the air to the screen would obviously tend to decrease the heat radiation from the latter and might therefore have the effect of retaining its temperature and of increasing its luminosity in comparison with another screen not so acted upon.

I should like to add that personally I have been investigating the "n" rays not so much from a physiological as from a physical standpoint and the greater part of my experiments have so far been directed to ascertain the existence of these rays as given off, according to M Blondlot, by Auer incandescent gas mantles and by Nernst electric lamps. So far I have been quite unsuccessful in convincing myself that these "n" rays have any real objective existence at all, but without definitely concluding that the effects observed are subjective I am quite ready to admit that there may be effects visible to some persons to which I myself and my assistants and others who have also obtained negative results are blind It may, in fact be a matter similar to "colour blindness" only in another form. In any case, however, I would warn experimenters in this most interesting field that the subject is full of pitfalls The accurate observation of these dim phosphorescent objects is really very difficult owing to the fact that different parts of the human retina are very unequally sensitive to faint lights, while optical fatigue and other phenomena are apt to obscure the results.

I am, Sirs, yours faithfully,
A. A. CAMPBELL SWINTON.
Westminster, S.W., Feb. 29th, 1904.

HUMAN AND PLANT RAYS.

To the Editors of THE LANCET.

SIRS,—Having recently been in Paris I had whilst there an opportunity of an interview with Dr. Baraduc who was kind enough to give me a prepared screen by which to demonstrate the "n" rays The other night Dr. Hugh Walsham and I were experimenting with this screen. We first of all excited it by means of an ultra-violet lamp after which we easily obtained luminosity when it was in contact with any part of the surface of the body, but, as I told Dr. Walsham, its excitation by the lamp was by no means necessary after each test. This was proved by first allowing all prior emanations to pass off, then, when no glimmer of fluorescence was perceptible, we placed the screen on the floor at a distance of three feet from where we stood. All was total darkness, but after placing my finger under the screen for a minute the glow was quite apparent.

To show that these emanations were not due to heat rays, we filled a hollow metal lens (made for the purpose) with very hot water and held the screen quite close to this lens; there was absolutely no brightening, in fact the illumination caused by the previous contact with my temple gradually dulled down while the screen was still in the path of the caloric rays. I also lodged the screen, after allowing a sufficient interval of time for previous emanations to pass off, amongst the branches of a mimosa plant; the luminosity appeared in a few minutes and in this case apparently could not be due to heat rays. Personally I have known for some years, and have satisfied myself on the point scores of times, that rays (vibrations) are given off from all organic beings and inorganic substances; those emanating from ourselves I have usually designated "human rays." It is common knowledge among all who have dipped into occult matters that these "etheric vibrations" have been demonstrated by Reichenbach 50 or more years ago. "Emanations" from human beings are referred to by learned Indian writers as far back as 2000 B.C.—and before that for all I know to the contrary.

I am, Sirs, yours faithfully,
J. STENSON HOOKER, M.D. Durh.
Gloucester place, W., Feb. 22nd, 1904.

THE CAUSES OF HIGH INFANTILE MORTALITY.

To the Editors of THE LANCET.

SIRS,—I cordially welcome your remark (p 452) that "the children of the poor are a national asset" and ask permission to say a few more words on this subject. Dr. J. M. Rhodes's figures (p. 462) show, what no one doubts—viz., that density of population is a cause of high infantile mortality They do not show that restriction of medical relief is not also one of the causes; hospitals and dispensaries will not make up for the medical man's visits and advice at the home Sometimes the baby is taken back from the hospital to die; it ought not to have been brought out into the cold. Dr. Rhodes's figures as to the counties are not of much use as the counties comprise unions which vary as to relief and also as to density. They do, however, suggest (what, indeed, we know) that ignorance of mothers is one of the causes. I quite agree with Dr. Rhodes that the custom of the mothers of infants working in factories is another cause. In both these cases the advice of the medical adviser would be most useful and, if followed, might save many lives I think the guardians, also, should, in the case of children for whom they give out-relief, allow milk instead of the usual loaf And in the case of nursing mothers it might often be well to allow milk for the mothers.

As to my London figures I think a glance down them will show that, though they do not actually prove that restriction of medical relief is one of the causes of infantile mortality, they do make it worth while for a medical officer of health, where high infantile mortality exists, to inquire into the matter.

Let me add a few words from Mr. Charles Booth's final volume on "Life and Labour of the People of London." He gives at p. 17 a valuable list of districts in order of death-rate, poverty, &c. He says (p 18):—

> In St. George's-in-the-East and Shadwell the death-rate is at its highest, although this district stands only fourth in crowding, sixth in poverty, and eighth in its birth rate. For this discrepancy there is no very obvious explanation. It is, however, probable that the high death-rate has been connected with the intermittent and exposed character of much riverside labour. ...... Bethnal Green stands about fourth in everything except death-rate, which is as unaccountedly low as that of St. George's-in-the East is high.

It will be seen that the infantile mortality of St. George's-in-the-East is also far above that of Bethnal Green; and I would suggest that the different action of the guardians may possibly account for a part of the difference. I think also that the death-rate among the non-Jewish portion of the population of Whitechapel requires attention but cannot venture to take up more space in this letter. I should add that St. George's-in-the-East guardians have practically abolished ordinary out-relief but do give some medical relief.

I am, Sirs, yours faithfully,
Feb. 25th, 1904. J. THEODORE DODD.

THE PROPOSAL TO PROHIBIT MEDICAL PRACTITIONERS FROM DISPENSING.

To the Editors of THE LANCET.

SIRS,—Those who have followed the recent discussion in THE LANCET on dispensing by medical men will have noted that the question of prohibition has been treated by its opponents almost exclusively from a commercial point of view. They trouble themselves but little to reflect whether the interests of the medical profession as a whole are better promoted by prescribing or by dispensing, which of the two systems is more just in its relation to the public or which tends more to efficiency in practice. Yet these are considerations of the highest significance which must in the end govern and include the commercial. Let it not be thought that I undervalue the latter. I fully admit its importance, but it is clear that the foundation upon which it rests, the character and quality of work done, is more important still. The reform of a system which entails upon practitioners the discharge of services tedious in themselves and not essential since they are proper to the druggist, cannot but tend to increase their professional usefulness. The assumption that his drugs are superior to those of the chemist is a pure invention. What, after all, do the arguments against the supersession of dispensing amount to? It is asserted that patients will not consent to pay both doctor and chemist, that they will prefer to be treated by the latter, and that they will be "driven" to dispensaries and hospitals. No proof is adduced in support of these assertions. We are asked to accept as virtual certainties what are at best merely suggested probabilities. I have found that in my mixed practice patients do pay both me and the druggist and, as a rule, without demur. I doubt if even in club attendance an adjustment equitable to the members and satisfactory to both practitioner and chemist would prove impossible if only medical men were united in trying to bring it about. One of your correspondents, writing with evident knowledge of the subject, assures us that the prescribing chemist is practically non-existent, and it would be difficult to conceive a system better calculated than the present to encourage retaliation by the chemist upon the practitioner. As to dispensaries, the worst offender of them all, the cheap private dispensary, would be suppressed by prohibition and the medical profession generally would rejoice in its overthrow. Hospital abuse is so prevalent already that if dispensing practice is to be considered an antidote to this disease it is surely one of the mildest. It is improbable that any remedy for it will be obtainable until we discover a hospital conscience of reliable strength. The real crux of the difficulty which stands in the way of prescribing, however, is not to be looked for in any of these objections. It consists in the disinclination of many medical men to part with what they regard as their vested interest in a prescription. In other words, the remedies dispensed for or by them are considered to be proprietary and a patient every time that he has to renew his bottle of physic must be credited with a fresh consultation. This may be a profitable transaction so far as the practitioner is concerned, but I do not think it should be regarded as professional. Treatment only, not the sale of drugs, is the true function of a medical man. If he requires to supervise his patient's condition he ought to instruct the latter to this effect, and he is not likely in that case to see him less frequently than he is entitled and required to see him. If he fails to advise his patient so, he has only himself to blame. I am aware that investments in practice grounded on existing conditions cannot be lightly set aside, and for this reason I would not, in the interest of practitioners who may be pledged to the present order, support the immediate prohibition of dispensing. At the same time I regard the system as a bad one at best and as meriting the expressed disapproval of the General Medical Council. Later, after due notice and the lapse of a compensatory period of grace, with possible exemptions in the case of senior men and outlying districts, prohibition might well follow with advantage to all concerned. Let it be remembered that the abolition of dispensing would bring with it obvious benefits in return for losses sustained. In a letter to the *British Medical Journal* of last week I drew attention to the reduction of working expenses which must result from it and I suggested that an inquiry into the comparative profit or loss by dispensing or prescribing should be instituted. If this were done we should at all events learn something of definite use for our guidance on the commercial aspect of this question. No one, I am sure, would wish to bear hardly upon honest practitioners who are doing their best under an arrangement for which they are not primarily responsible or to force upon them a change of method which they might find to be injurious. Any reform of the kind contemplated must be gradual, but it can hardly fail to come, and I trust it will receive an increasing measure of support from all medical men who have the best interests of their profession at heart. I am, Sirs, yours faithfully,

Highbury, N., Feb. 23rd, 1904. B. G. MORISON.

To the Editors of THE LANCET

SIRS,—I am one of the now almost obsolete class who entered the profession by the apprentice's door and there learned something of, and handled, the weapons with which I was to fight disease before meeting the enemy. In my case familiarity has not engendered contempt. History repeats itself and 100 years hence may see a return to the good old system of beginning at the ladder's foot. Among some of the traditions of those days was to consider nothing for the relief of humanity derogatory, to spare no expense in procuring the best of drugs, and to secure a fitting remuneration for all professional services. Now this is to be reversed, the touching of drugs defiles, yet the sum of 1*s.* may be pocketed for valuable advice without dishonour or lowering the standard of the profession. How and when did this change come? Is it but a fashion? Are we who for 50 years have been dispensing our own medicines and keeping up reasonable charges to be accused of infamy? If so, there will be a large secession from the ranks, but piracy means independence and an easier mode of living than under grandmotherly laws.

Dispensing is no doubt both troublesome and expensive, but it benefits both patient and doctor. In the vast proportion of cases drugs are quite secondary to the advice, encouragement, or correction of habits, and reformation can seldom be maintained but by steady and frequent watching and interviews. The drugs, too, may need changing. Yet how often do we meet a man perseveringly for months hoping for benefit from a prescription because it was ordered (often with a single interview) by some great celebrity. His faith is in the drug; he is too busy or idle—often too stingy—to meet his doctor regularly.

Then, how much easier is it to help the hypochondriac or neurotic without showing him a prescription, each drug of which he may despise from long use, or consider poisonous or objectionable in his case. If we thought less of ourselves and our dignity and more of how best to benefit those who seek our help the large proportion of practitioners would admit that home dispensing gave the better results to both doctor and patient. These are the views of

Yours faithfully,

Feb. 27th, 1904. AN ANTEDILUVIAN.

THE ADULTERATION OF COD-LIVER OIL.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the communication from Dr. L. A. Parry referring to the views I have expressed in regard to cod-liver oil. I should like to point out, however, that I do not for a moment suggest that cod-liver oil is not an excellent remedy for certain diseases—what I suggest is that its effect has been ascribed to so many different "active principles" none of which appear to have any reference to its real value that one can scarcely help being convinced that it owes its efficacy to its fatty nature and easy digestibility and not to traces of iodine, nor to "gaduine," nor to Marpmann's ferment, &c. If this is so my use of the word "traditional" was not meant to suggest that cod-liver oil had no value, but that it had been used for generations on the assumption of its possessing some virtues foreign to its fatty nature which have never been shown to exist, with the results that many other fats have never been taken into serious consideration as medicaments. I know that marrow fat (in the form of Virol, a preparation which contains no fish oil, but marrow fat) has been employed in the hospital which Dr. Parry refers to and I believe that, for example, marrow fat is one of those forms of administering a remedy of this kind with great efficacy, and all that my contention amounted to is that the easy digestibility of a given fat will largely determine its medicinal value. At all events, proof to the contrary has never been adduced. I am, Sirs, yours faithfully,

ERNEST J. PARRY.

High-street, Borough, S.E., Feb. 25th, 1904.

BILHARZIA HÆMATOBIA.

To the Editors of THE LANCET.

SIRS,—In answer to Mr. E. H. Worth's query in THE LANCET of Feb. 27th, p. 611, urotropine should be tried in cases of cystitis and hæmaturia caused by the bilharzia hæmatobia. This drug sometimes clears up the cystitis and kills the ova of the parasite. It seems to have no effect, however, on the adult worms, for in these cases, on discontinuing the drug, ova are again passed in the urine from which living embryos can be hatched. Some cases, however, prove most intractable and the disease may last for years. For instance, a soldier who was invalided from the Cape in 1901 still suffers from hæmaturia in 1903, ova still being present in the urine. Methylene blue may also be tried with advantage in some cases. I am, Sirs, yours faithfully,

E. H. ROSS,

H.M.S. *Anson*, Home Fleet, Feb. 28th, 1904. Surgeon, R.N.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a circular (a copy of which I inclose) in which my name appears prominently in connexion with the advertisement of a proprietary medicine. I desire to state that I know nothing of the preparation in question, that my name has been made use of in a way which I consider wholly unwarranted and without my knowledge or consent, and that I have written to the proprietors of the preparation requesting them to discontinue the issue of the circular at once.

I am, Sirs, yours faithfully,

Queen Anne-street, W., Feb. 24th, 1904. ROBERT HUTCHISON.

⁂ Every medical man receiving the circular must have sympathised with Dr. Hutchison in the abuse of his name.—ED. L.

PORTUGAL AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—During the last few years there has been a constantly increasing stream of English tourists and invalids visiting Portugal and the stream has decidedly increased since the visit of King Edward to Lisbon in the spring of last year. It is not my intention to guide the tourists as to what they should do, but I wish to put in a *caveat* regarding the invalids. I have noticed with regret that some of the medical men in Great Britain have not yet accurate ideas regarding the climatic capabilities of Portugal. In their view Portugal means Cintra, Bussaco, or Lisbon, and consequently when an invalid comes here he goes to one of these places. Each of them is no doubt excellent in proper seasons and in proper diseases, but to send an invalid recovering, say, from a lung complaint or rheumatism to winter in any of them when there are far better other places within easy reach is, to say the least, extremely injudicious. Cintra, which is situated on the northern side of the Cintra range, is an excellent health accommodation, although the question has been frequently pressed upon the board for some years by the inspector of the Local Government Board. At a meeting of the guardians held on Feb. 26th a lady member said that it was quite time that the board as a whole should know how matters stood with regard to the sick wards and infirmaries of the workhouses. Children, she declared, were put in the same wards as consumptive patients, there was no classification of diseases, the patients being indiscriminately mixed up, and not only the wards but the beds were overcrowded for there were 89 patients in 80 beds.

Merthyr General Hospital.

Sir William Thomas Lewis, the president of the Merthyr Hospital, offered last year to bear the cost of extending the women's ward to accommodate eight more patients provided that public subscriptions were forthcoming to insure the addition of a similar extension on the men's side of the hospital. The high constable of the town, Mr. C. Biddle, M.R.C.S. Eng., L.R.C.P. Lond., collected through a shilling fund nearly £700 for this purpose and as about the same amount has been subscribed in addition the extensions to the institution are insured. The question of providing the necessary income for the support of these 16 extra beds is now being discussed by the hospital board and the workmen of the district. The latter ask that there shall be an addition made to the present staff of four surgeons in the event of increased contributions by the men.

Treatment of Vagrancy.

At the conference of the Somersetshire Poor-law guardians and rural district councillors recently held at Highbridge a motion was passed expressing the opinion that the question of the treatment of vagrants is one that deserves serious attention and suggesting that the Local Government Board should appoint a departmental committee on the subject. The members of the conference also expressed approval of Sir John Gorst's Bill which provides for the better protection of vagrant children but it was considered that the cost of enforcing the measure should be borne by the Imperial Exchequer.

The Midwives Act in Glamorgan.

At a meeting of the sanitary committee of the Glamorgan county council held on Feb. 26th it was decided to recommend the appointment of a female inspector in connexion with the administration of the Midwives Act. A proposal to include two or three women in the committee appointed to administer the Act was not adopted. There are said to be about 700 midwives in the administrative county.

March 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

A Degree in Dentistry at Trinity College, Dublin.

THE annual meeting of the Incorporated Dental Hospital of Ireland took place on Feb. 18th in Dublin, Mr. William C. S. Stubbs occupying the chair. The report of the Dental School stated that its labours in the cause of dental education had met with the approval of the University of Dublin which had decided to grant a degree in dentistry. Sir Christopher J. Nixon proposed the adoption of the report and Sir John W. Moore moved "that the Incorporated Dental Hospital of Ireland is worthy of support."

The Samaritan Hospital, Belfast.

At the annual meeting of the supporters of this charity held on Feb. 24th it was stated that during the past year 636 patients were treated in the extern department and 172 in the wards. Of the latter 113 required surgical operations Mr. J. M. Finnegan has placed a quantity of radium at the disposal of the medical staff of the hospital for use in cases of cancer. Electric light, the Roentgen rays, and electric heat and light baths were much needed in the hospital. The debt of the institution has by an effort been reduced to £230 2*s.* 10*d.* As the annual subscriptions amount only to £151 the committee wisely considers that an effort should be made to widen the basis of these subscriptions and by increasing the income under that head to obviate the necessity for frequent special appeals for money to discharge debts.

The Belfast Maternity Hospital.

At the 110th annual meeting of the supporters of this institution held on Feb. 25th it was reported that during the year 326 intern patients had been admitted into hospital with only one death; there had been 304 extern midwifery cases and 458 gynæcological cases. The new building for the hospital has been begun in Townsend-street (a very populous part of the city). In addition to £2751 already in hand £6000 are needed for the building and furnishing of the new maternity, and of this sum £4100 have already been promised or paid since Nov. 20th, 1903. Reference was made at the meeting to the new regulations of the Central Midwives Board and it was hoped that the endeavours of the medical staff of the Belfast Maternity Hospital to have the slight thrown on the hospital removed would be successful.

March 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disturbances at the Faculty of Medicine.

FOR a week or two past the medical students of the Faculty of Paris have been in a state of lively effervescence which has manifested itself by rows which have been of almost daily occurrence. Bands of students have invaded the lecture rooms uttering songs and shouts which have only ceased on the professor leaving off his lecture and going away. On Feb. 19th the students went so far as to break the windows in the practical school and to carry away the doors, which they took into the street and broke up to make a bonfire, round which they danced. These demonstrations, which have already cost some thousands of francs and which the university authorities regard with inexplicable calm, are organised, according to their originators, to a double end. On the one hand they wish to protest against the recent law which allows retirement in the case of professors at a later age than formerly, and on the other hand against the appointment of M. Chantemesse to the chair of hygiene in exchange for that of pathology which he formerly occupied. In so far as regards the new law which has just been passed by the Senate it is quite certain that instead of the age limit being 65 years for ordinary professors, 70 years for professors of a clinic, and 75 years for these last-mentioned when they happen to be members of the institute, the new law will permit the holder of a chair to keep it for much longer than formerly and that the infusion of new blood into the general body of professors will take place exceedingly slowly, a fact which will seriously affect the promotion of the younger class of *agrégés*. The new law, however, which has in view all State officials, was not passed specially with regard to professors, but at the instance of the Finance Minister who complained of the waste of public moneys caused by the necessity for giving retiring pensions to office-holders who were dismissed by the various Ministries in order to find places for their political protégés. This necessitated a double impost on the taxpayer, for he had to find the salary of the newly-appointed official and a pension for him who was retired. In the magistracy and in the administration, for instance, it was quite usual for a Minister to allow an official to retire who was still quite capable of good work in order to find the sooner a place for an applicant who might be backed by some influential deputy. The double expense mentioned above decided the Minister of Finance to alter the age limit so that in certain directions at least some economies should ensue. It must be allowed that the law is badly drafted, for it prevents the infusion of new blood into scientific circles which are just those where the above-mentioned governmental manœuvres have hitherto had least influence. No Government can with ease make a political creature a professor of the Faculty of Medicine any more than it can make him a judge or a prefect. The law also puts an end to the prospects of many hard workers whose hopes of advancement are postponed to an indefinite date, for many professors will live to 80 years of age. On the other hand, whatever may be the value of a scientific man there inevitably comes a time when his views cease to be in touch with modern progress and when instead of making for improvement he contents himself with repeating and defending his own personal opinions which represent his past period of activity. As for the economies which the new law is intended to bring about they may be neglected, for there will continue to be wastage in all the administrative posts so long as the Government continues to dispose of these as mere monetary payments. The protest against the appointment of M. Chantemesse has its origin from quite a different source. The chair of hygiene, which was vacant by the death of Professor Proust, was canvassed for by the *agrégés* who were specialists in hygiene. M. Chantemesse, by taking this chair in exchange for that which he already filled, ruined their expectations, for he is one of the youngest of the professors and may be reasonably expected to hold his post for 20 or 25 years. M. Chantemesse's apparent object in asking to be allowed to exchange was a wish to obtain the post of inspector-general of the sanitary service which Professor Proust held together with his chair of hygiene. As a matter of fact he has obtained the post, for it is almost invariably an appanage of the chair of hygiene and the holder of the two posts enjoys a magnificent salary. This fact aggravates the despair of the disappointed *agrégés* and it is strongly suspected that they have egged on the students to provoke the disturbances. The protests, however, have been of no avail, for they deal with two accomplished facts—one due to a law passed by the Senate and the other to an exchange brought about in a perfectly orthodox manner by M. Chantemesse after formal authorisation by the council of the faculty which was ratified by the council of the University, although not unanimously, it is true The Dean, M. Lebove, has refused to punish the rioters, declaring that the matter is one which concerns the internal affairs of the university and that he does not wish to call in the police Nevertheless, something will have to be done, for several courses of lectures, notably those delivered by M. Blanchard and M. Poirrier, have been suspended and such a situation will compel the dean to interfere.

French Ambulances for the Russo-Japanese War.

The central council of the Society for the Relief of the Wounded in War has just held a meeting in Paris under the presidency of the Marquis de Vogüé. The council has ratified the decision of its finance committee to allot a credit of 250,000 francs for the installation of four field hospitals to be sent to the Far East. Two of these hospitals will accompany the Russian army and the other two will go with the Japanese. Each hospital will be made up of 100 beds, 22 cases containing drugs, instruments, and dressings, and six bales containing various articles of bedding. The staff of the hospitals to accompany the Russian forces will include a number of medical officers, hospital orderlies and nurses, and a finance officer (*comptable économe*) who will be responsible for expenditure and the like At its next meeting the council of the society will proceed to decide upon the details of the expedition. It is hoped that at this meeting the answers of the Russian and Japanese Governments will be received. These two Governments have been officially advised of the intentions of the society and their favourable response to the scheme is necessary before the hospitals can be dispatched.

March 1st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

International Agreement on Measures for the Prevention of the Spread of Yellow Fever.

THE United States and the Mexican public health authorities have, for the first time, come to a mutual agreement as to the measures which each will adopt and enforce to prevent the spread of yellow fever. This convention will undoubtedly prove of the utmost importance to both countries in the prevention of the pestilence which annually appears in the seaports near the border lines of the two nationalities. The first requirement is the prompt report of all cases of suspicious fever to the local health authorities where they occur, the immediate screening of the patient, and the destruction of mosquitoes on the premises, pending the making of the diagnosis. The occurrence of the first authentic cases of yellow fever in either republic will be immediately reported by wire to the other republic Secondly, vigorous methods of post-epidemic fumigation with sulphur will be inaugurated without delay in both republics in places where infection has existed during the latter part of the past year. Thirdly, there will be efficient sanitary measures in towns and places which have been infected with yellow fever during the past year as follows: burning of brush; drainage of all stagnant water; oiling of all stagnant water the drainage of which is impracticable; all water containers to be treated at least once, and oftener if necessary, with a thin film of refined oil deposited upon their surfaces and to be screened tightly and to be covered constantly to prevent access of mosquitoes, a penalty to be imposed for the absence of the said screens and covers. The convention also provided that the agents of the Superior Board of Health of Mexico will be received in any town or place in the United States where yellow fever has prevailed to note the enforcement of the above provisions and to invite the attention of sanitary authorities to any lapse in the same. In like manner officers of the United States Public Health and Marine Hospital Service, detailed for duty in the offices of the United States Consulates in any Mexican city, will be granted every facility for observation as to the enforcement of the same measures in the cities and towns of Mexico that have been infected with yellow fever.

The Tuberculosis Exposition at Baltimore.

This exposition proved to be one of the most important movements yet made to enlighten the public in regard to the nature and prevention of tuberculosis. The formal opening took place on Jan 25th and was largely attended by the public. Addresses were given by the Governor of the State, the Mayor of the city of Baltimore, and Professor W. Osler of Johns Hopkins University. On the following days addresses were made by men prominently identified with the movement to suppress tuberculosis and large numbers of people were attracted to the exposition. The exhibit consisted of a variety of objects which illustrated the nature of tuberculosis, its prevalence, and the measures employed against it. There was a pathological department containing specimens of tuberculous tissues and organs in man and animals, wax casts, and the like, from the Army Medical Museum and from the museums of the University of Maryland, the Johns Hopkins Hospital, the Baltimore College of Physicians and Surgeons, and the city and State health departments. The exhibit of prophylactic measures employed by State and municipal boards of health attracted deserved attention and were exceedingly instructive to the public. This exhibit included a variety of tents for sufferers from tuberculosis, spitting-cups, sleeping cots, and so on.

The Dangers of Football.

The statistics of the fatalities and injuries in the game of football have been collected by the *Journal of the American Medical Association* and present a surprising record of severe casualties. The number of deaths occurring in this game during the year 1903 was 35 and there were over 500 severe accidents. Besides these 35 deaths there were 11 cases of spinal injuries followed by paralysis, which seem in most instances to have proved permanent and consequently were worse than death. Sprains, contusions, and scalp wounds are not included in the list, although reports show that many of these injuries, which at first were considered trivial, finally resulted seriously. There were 343 fractures, most of them of the bones of the leg and the forearm There were 91 cases of fracture of the clavicle, 19 fractures of the femur, and four fractures of the skull. While it is impossible to estimate accurately the number of permanent injuries caused by these accidents it is evident that they could not be very low when it is considered that many of the fractures were compound and 19 were of the femur. It may be stated without exaggeration that at least 60 deaths or permanent total disabilities resulted from the game of football in 1903.

Civil Service Examinations for Medical Clerks.

The United States Civil Service Commission is about to [illegible] different large cities of the [illegible] s of the [illegible] from 25 [illegible] schools [illegible] citizens [illegible] is The course of examination will be: (1) letter writing, the candidate being allowed to select one of two subjects which are of popular interest; (2) penmanship, as regards legibility, rapidity, neatness, and general appearance; (3) copying, a test of two exercises, the first being an exact copy of the text given and the second the writing of a rough draft manuscript, including correction of all errors; (4) anatomy and physiology; (5) diagnosis; (6) general and special pathology; and (7) surgery and surgical pathology. These examinations are a great advance in the qualifications of persons entering the civil service of the country and will tend to the elevation of the character of the service.

Tuberculosis in Prisons.

During the last two or three years the medical profession has directed attention with striking results to the importance of protecting prisoners from the contagion of tuberculosis. The report of the physician of one of the first to take action—viz., the prison of the State of Minnesota—states that the segregation of prisoners suffering from tuberculosis was begun in 1894. A set of cells was devoted especially to inmates who proved on careful examination and proper tests to be affected with tuberculosis. These cells also received scrupulous sanitary care as to ventilation, cleansing, and disinfection. The prisoners occupying these cells were kept much in the open air at work. The result has been remarkable; in three years the number of tuberculous inmates had been reduced by 52 per cent. At present there are 630 inmates with but six tuberculous cases and these came in with the disease but are all improving. Many other States are segregating the tuberculous inmates in properly prepared quarters.

Feb. 19th.

Medical News.

University of Cambridge.—On Feb. 25th the following medical and surgical degrees were conferred:—

Doctor of Medicine.—R. N. Salaman, Trinity Hall.

Bachelor of Medicine.—G. E. St.C. Stockwell, King's; F. A. Hepworth, St John's; H. J Robinson, St. John's; G. P. D. Hawker, Gonville and Caius; P. K. Muspratt, Christ's; and S. J. Steward, Downing.

Bachelor of Surgery.—F. A. Hepworth, St. John's; H. J. Robinson, St. John's; W. B. Swete-Evans, Clare; and W. Hyde Hills, Pembroke.

The Medical College, Lahore, has been recognised as a medical school and the City Hospital for Infectious Diseases, Newcastle-on-Tyne, as a fever hospital by the special board for medicine.

Subsidences of Land at Bardsley.—Some little time ago the dangers arising from old disused pit shafts were brought prominently into notice by the tragedy at Hanley, where a man was swallowed up when walking along the open street; and recently a family at Bardsley, near Manchester, had a somewhat similar though happily a less tragical experience. A gentleman built a house there not knowing that it was on the brink of a disused colliery shaft; hearing a rumbling sound one night he got up and, with his son, went into the back yard. Fortunately they did not open the gate leading to the garden, for a footpath and part of the garden had disappeared, leaving a great chasm into which they would have stepped. The whole family sat up through the night fearing that the house would go. Next day they quitted it. The hole is increasing in size and the surroundings of the shaft are giving way. The covering of the shaft seems to have been about six feet of clay and soil. The people about are naturally anxious, for they fear there may be many such death-traps, as within the memory of people living several pits have ceased working within the last 50 years. It is said that the pit shafts in the neighbourhood are very deep and that probably the depth of the one that has collapsed is between 500 and 600 yards. Very possibly the great amount of rain during the last year or two may have had a share in causing these subsidences, but however that may be it must be a horrible idea that you may suddenly go down into the pit. Surely there is sufficient cause for a very careful inquiry as to the exact position of these disused pits not only in this but in all mining districts.

The Middlesex Hospital.—The annual court of governors, at which the Earl of Lathom presided, was recently held at the hospital. The court had before it two separate reports, the one dealing with the work of the hospital and its convalescent home branch at Clacton-on-Sea, and the other with that of the Cancer Charity. From the former is gleaned the fact that all the various building improvements which have been in course of construction during the last five years are now complete and the hospital may be said to be equipped with every known appliance for the treatment of its patients. These various alterations during the last decade have comprised *inter alia* the enlargement of some of the wards for females, the building and equipment of a separate department (with a special operating theatre) for the treatment of diseases of women, the erection of a new home for the nursing staff, the removal of the hospital kitchens from the basement to the top floor, the removal of the laundry from the hospital to a site in the country, the installation of a new boiler-house, and the erection of a cold storage plant and disinfecting apparatus. The cost of all these alterations has been considerable, so that the hospital now finds itself, after having realised a considerable amount of its capital, still in debt to the bankers to the extent of £20,000. With the object of repaying this debt a festival dinner is to be held in May next. With regard to the work of last year the statistics show that 4095 in-patients and 48,744 out-patients, as well as 272 patients who attended for the "light" cure, were treated at the hospital, and 979 patients were sent to the hospital's home at Clacton on-Sea. The second report submitted—that of the Cancer Charity—is the first of its kind and after dealing with the financial affairs of the charity gives the statistics of the patients treated. It mentions the fact that the charity is now regarded as a separate institution by both the Hospital Sunday and Saturday Funds, which make awards accordingly. Dealing with the treatment of the patients, mention is made that 100 cases of carcinoma were treated with 3040 applications of the x rays with distinctly encouraging results; that in the laboratories much time had been devoted to the testing of alleged "cancer cures"; and that no so called cure submitted had been neglected but all had as yet proved fruitless. The director of the laboratories, Dr. W. S. Lazarus-Barlow, has been appointed a member of the German Cancer Investigation Committee, so that the two bodies are able to work together

The Central Midwives Board.—At a meeting of the Central Midwives Board held at the office in Suffolk-street, London, S.W., on Feb 25th a communication was read from the Royal Academy of Medicine in Ireland pointing out that the pupil midwives of the Irish Chartered Maternity Hospitals could not personally deliver 20 women as required by the rules of the Board. A resolution was inclosed stating that the Obstetrical Section of the Royal Academy of Medicine in Ireland was of opinion that any woman holding the certificate of the Irish Chartered Maternity Hospitals should be deemed to have complied with the rules of the Central Midwives Board regulating the course of training of pupil midwives. The Central Midwives Board replied to this communication, as it had replied previously to similar communications from the Master of the Rotunda Hospital and to Professor J. W. Byers of Belfast, that the Board cannot alter the rules now that they have been approved by the Privy Council. After consideration of applications for certificates the names of 917 women were passed under Section 2 of the Act and ordered for entry on the Roll. Of this total one claimed as holding the certificate of the Royal College of Physicians of Ireland, 291 that of the Obstetrical Society of London, nine that of the Rotunda Hospital, four that of the Coombe Hospital, 14 that of Queen Charlotte's Hospital, nine that of the Liverpool Lying-in Hospital, two that of the British Lying-in Hospital, three that of the Glasgow Maternity Hospital, 11 that of St. Mary's Hospital (Manchester), three that of the City of London Hospital, one that of the Salvation Army Hospital, and 569 were admitted as having been in *bonâ fide* practice for one year prior to July 31st, 1902. The question of the payment of a registered medical practitioner sent for on the advice of a midwife in compliance with Section E, Rule 17, of the rules of the Board was considered. After discussion it was resolved unanimously:—

> That inasmuch as no provision is made in the Midwives Act, 1902, for the payment of legally qualified medical practitioners, the Government be requested to take the necessary steps for amending the Act by introducing a section or otherwise to provide for the payment of legally qualified medical practitioners when called in by midwives in difficult cases.

Literary Intelligence.—The following new books and new editions are to be published in the spring by Messrs. J. and A. Churchill: "The Examination of Water and Water-supplies," by Dr. J. C. Thresh, lecturer on Public Health at the London Hospital Medical College. The work will be freely illustrated. "A Handbook of Surgical Diagnosis," by Mr. James Berry, surgeon to the Royal Free Hospital. An illustrated work entitled "The Elements of Chemistry," by Mr. M. M. Pattison Muir, Fellow and Prælector of Chemistry at Gonville and Caius College, Cambridge. "Unconscious Therapeutics, or the Personality of the Physician" by Dr. A. T. Schofield. The sixth edition of "Clinical Lectures on Mental Diseases," by Dr. T. S. Clouston, physician superintendent of the Royal Asylum, Edinburgh. In addition to the text being revised there will be some additional plates. The sixth revised edition of "A Manual of Anatomy, Dental and Comparative," by Mr. C. S. Tomes, F.R S.

AN ASYLUM "SCANDAL."—An unfortunate occurrence at the Tooting Bec Asylum of the Metropolitan Asylums Board has recently been the subject of comment in the public press and as the matter is one which may appeal to those concerned with the management of institutions for the care of the insane it may be advisable to put on record what, so far as we can learn, actually took place. Early in [illegible] who was for some [illegible] gged by a party of [illegible] nd there liberally [illegible] uring her struggles [illegible] injured nurse was [illegible] ssailants two of [illegible] ded from duty by [illegible] en admitted complicity and were also suspended and at the next meeting of the asylum committee the whole eight were dismissed. Possibly if the committee had been a court-martial the ebullition of animal spirits above described would have been regarded merely as an exhibition of playfulness in no way unworthy of nurses and ladies and rather to be encouraged than otherwise. It consisted, however, of plain men of business apparently unenlightened as to the higher ethics of "ragging" and they unanimously decided that the conduct of the attendants unfitted them for holding responsible posts in connexion with the nursing of the insane sick. Civilians generally will probably agree with this view. The asylum at Tooting Bec is a new one and the establishment of a precedent of leniency in regard to such a grave breach of discipline as undoubtedly occurred might have disastrous consequences in the future. Poor-law officials are peculiarly open to criticism on the part of the public and it is greatly to be regretted that the eight offenders in this case did not pause to consider the amount of discredit which their behaviour would be likely to entail upon both themselves and the institution with which they were connected. We trust that the incident will not be further endowed with fictitious importance by the garbled and exaggerated accounts of sensation-mongers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Another Nursing Bill.

A SECOND Bill dealing with nurses has been brought before the House of Commons. Its object is "to provide for the better training and registration of nurses and for the voluntary registration of private nursing homes." Mr. Claude Hay has made himself responsible for the measure.

The Revaccination Bill.

The opposition to the Revaccination Bill has now taken the definite form of a motion for its rejection which has been placed on the paper by Mr. Logan.

The Metric System.

[illegible] the [illegible] was [illegible] consented to act as a member.

The Sale of Poisons.

Mr. Lough has presented a Bill for the further regulation of the sale of poisons and the compounding of medical prescriptions and to amend the Pharmacy Acts, 1852 and 1868. A somewhat similar measure was brought before the House last session. The alterations made are chiefly in the direction of adding strength to the provisions. It is proposed, amongst other things, that every shop where poisons are sold should be under the conduct of a duly qualified person; that there should be a register of all shops where poisons are retailed and also of the chemists conducting the business, that "company" shops in which poisons are sold should be managed by duly qualified men; that the examination of persons desiring to qualify as chemists and druggists should be facilitated; and that the Pharmaceutical Society should be enabled to accept certain certificates of kindred bodies in lieu of examination.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 24TH.

Metropolitan Asylums Board and Treatment of Ringworm.

Sir WALTER FOSTER asked [illegible] Board whether any hospital [illegible] Asylums Board for the treat[illegible] ringworm and, if so, whethe[illegible] present in the hospital and [illegible] each year, the cost of the [illegible] for the maintenance of the institution.—Mr. LONG answered as follows. The Metropolitan Asylums Board has two establishments for the reception and treatment of Poor-law children suffering from ringworm—one at Sutton, Surrey, and the other at [illegible] 1903 (the date of opening) to the end of that year was 618. In the case of the other school, which was opened on Feb 12th, 1901, 316 [illegible]

Interpretation of the Vaccination Act.

Mr. RUNCIMAN asked the Home Secretary whether, in view of the diverse action of different magistrates throughout the country in the treatment of applications under Section 2 of the Vaccination Act, 1898, it is the intention of the Home Office to issue to magistrates [illegible] the issue of a circular such as the hon. Member suggests, which would, in the circumstances, serve no useful purpose.

The Purity of Milk.

Mr. CHAPMAN asked the President of the Local Government Board [illegible] Member.

MONDAY, FEB. 29TH.

Adulterated Whisky.

Mr. FLAVIN asked the Chancellor of the Exchequer whether his attention had been called to the character of some blends of so-called Irish and Scotch malt whisky; whether he was aware that a blend made up in a bonded warehouse in Scotland, the total amount of [illegible] dealt with in the [illegible] to the House.

The Sale of Poisons.

Sir THOMAS DEWAR asked the President of the Local Government Board whether his attention had been called to a coroner's inquest, held at Southwark on Feb. 23rd, when the jury, in returning a verdict of death by misadventure, added a rider that the sellers of acids and all poisons should be compelled to label the vessel with the na[illegible] word "poison" and [illegible] except in sealed b[illegible] on the subject wo[illegible] who replied, said [illegible] but as to further le[illegible] refer my hon. frien[illegible] March 4th last, ind[illegible] opportunity.

Medical Officers and Milk-supplies.

[illegible] Local Government Board [illegible] Prevention of Diseases) Bill, 1903. [illegible] as no doubt elimi[illegible] the Local Govern[illegible] ention to this cir[illegible] It was found, how-
cumstance in [illegible]
ever, that, notwithstanding this, the clause was in a large number of
cases allowed by committees. Moreover, a similar provision was made
for Scotland in the Public Health (Scotland) Act, 1897. In these cir-
cumstances the Board in 1899 discontinued the practice of drawing
attention in its reports to the action of Parliament in 1890 and I do
not propose to resume that practice.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADENEY, G. C., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician to St. Thomas's Hospital.

ASHDOWNE, WALLACE, F.R.C.S. Eng., has l Surgeon to the Metropolitan Hospital,

AUSTIN, E. C., M.R.C.S., L.R.C.P. Lond., l ing Surgeon under the Factory Act for the Broughton Astley District of the county of Leicester.

BENNETT, H. S., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Out-Patient Department at St. Thomas's Hospital.

BIRKS, G. T., M.B., B.C. Cantab, has been appointed House Surgeon to the Out-patient Department at St. Thomas's Hospital.

BIRT, A. C., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Out-Patient Department at St. Thomas's Hospital.

CARVER, N. C., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Out-Patient Department at St. Thomas's Hospital.

CLIFT, M. L., M.R.C.S. Eng., L.S.A., has been appointed Divisional Surgeon to the City-road Station, G Division Metropolitan Police.

GUTHRIE, T., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

HARNETT, W. L., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital

HOFFMANN, H. D., B.C. Cantab., has been appointed Ophthalmic House Surgeon to St. Thomas's Hospital.

KEYSER, CHAS. R., F.R.C.S. Eng., has been appointed Surgical Registrar to the Cancer Hospital.

LATHAM, C. H., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the Out-patient Department at St. Thomas's Hospital.

LEACH, R. E. H., M.B., B.Ch. Oxon., has been appointed Resident House Physician to St. Thomas's Hospital.

LECKY, H. C., M.B., B.Ch. Oxon., has been appointed House Physician to the Out-patient Department at St. Thomas's Hospital.

NEWTON, W. T., M.R.C S. Eng, L.S.A., has been appointed Divisional Surgeon to the City-road Station, G Division Metropolitan Police.

PINCHES, H. I., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

POUNDEN, J. C., M.D. Dub., has been appointed Certifying Surgeon under the Factory Act for the Alfreton District of the county of Derby.

PRINGLE, G. A., M.B., B.S. Dub., has been appointed Certifying Surgeon under the Factory Act for the Aughnacloy District of the county of Tyrone.

RICHMOND, G. E., M.D., B.S., B.A., B.Sc. Lond., D.P.H. Camb., has been appointed Demonstrator of Hygiene and Public Health at University College, London.

RICKETT, G. R., B.C. Cantab., has been appointed Resident House Physician to St. Thomas's Hospital.

ROSS, E. A., M B., B.C. Cantab., has been appointed Resident House Physician to St. Thomas's Hospital.

SEARS, C. N., M.B., B.S. Lond., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

SHIPWAY, F. E., M.B., B.C. Cantab., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

SMITH, KENNETH RAWLINGS, M.D., B.S. Lond., M.R.C.S., L.S.A., has been re-elected Medical Officer of Health of Totnes (Devon) for three years.

STOCKER, E. G., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Clevedon District of the county of Somerset.

WIGRAM, L. E., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

WORGER, THOMAS HEWLETT, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health of Radstock (Somerset).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY COUNCIL, 68, Victoria-street, S.W.—Eight Dental Surgeons. Salary £365 per annum and travelling expenses.

AYR DISTRICT ASYLUM.—Assistant Medical Officer, unmarried. Salary £120, with board, apartments, attendance, and washing.

BIRKENHEAD BOROUGH HOSPITAL.—Senior and Junior House Surgeons (resident). Salaries £100 and £80 per annum and fees.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House Surgeon. Salary £75 per annum, with board and attendance.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £150 per annum, with rooms, fire, lights, and attendance, and allowance for cab hire.

BRENTFORD UNION INFIRMARY, WORKHOUSE, AND SCHOOLS, Isleworth. —Medical Superintendent and Medical Officer. Salary £300 per annum, with residence, rations, washing, &c., and fees.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Resident Junior House Surgeon, for six months. Salary £50 per year, with board, apartments, and laundress.

CUMBERLAND INFIRMARY, Carlisle.—Resident Medical Officer. Salary at rate of £80, with board, lodging, and washing.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

HORTON INFIRMARY, Banbury.—House Surgeon. Salary £80 per annum, with board and residence.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory Act at Banff, in the county of Banff.

Births, Marriages, and Deaths.

BIRTHS.

ORMEROD.—On the 28th February, at Beauchamp Lodge, Wimborne, the wife of Ernest William Ormerod, M.D. Camb., of a daughter.

WARRINGTON.—On Feb. 17th, at Rodney-street, Liverpool, the wife of W. B. Warrington, M.D., M.R.C.P., of a son.

WELLBY.—On Feb. 25th, at Fletham, Liss, the wife of S. Wellby, M.D., of a daughter.

DEATHS.

DIXON.—On Feb. 22nd (sud Southsea, James Deighton Dixon, M.B., R.C.S.,

MACARTNEY.—On March 1s in his L.R.C.P., late of 75, Jerningham-road, New Cross, 43rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CLUB PRACTICE MEDICINE.

To the Editors of THE LANCET.

SIRS,—If I might venture to offer any advice to "Inquirer" *re* Hunyadi Janos water in club practice it would be to recommend the patient strongly to have nothing whatever to do with it and to tell him that what was one man's medicine was another's poison, but, of course, if he (the patient) thought it worth his while to procure some for himself and try it he (the medical man) would have no objection provided he was not expected to pay for it. I should also reserve to myself at the same time the right of deciding what was "medicine" and what was not, as a lay committee of working men cannot possibly know anything of that question.

The clubs and contract system are as bad as they can be but that is no reason why we (the medical profession) should *lose* by them. There are many mixtures which go by the name of "club mixtures," and what are their main characteristics? Firstly, the most important, they *must* be the cheapest procurable; and secondly, they must be decidedly unpleasant to take. If club members prefer to deal in the cheapest market, is it not only reasonable that they should have the cheapest goods? Whilst discussing this subject of clubs I should like to ask how it is that they continue to exist, when *apparently* so many medical men object to them. Club members' wages have risen considerably since the clubs were founded, so this cannot be the reason; if they supply a real need why should not the fee be made in proportion to the work done? For instance, instead of a fixed sum per annum why should not the fee for visit and medicine be fixed at 2*s.* 6*d.* (of course, within a certain radius) and 1*s.* 6*d.* for advice and medicine at the surgery, these fees to come principally from the general body of the members but also a small proportion of each fee from the patient himself, say 3*d.* in the 1*s.*; he would undoubtedly attach more value to his medical man's advice and services and *vice versâ* the medical man would feel that he was to a certain extent being paid by the patient himself and would have a better feeling towards him. Of course, all fees to be collected and paid to the medical man by the secretary. This system would do away largely with that malingering one sees so much of in club practice and also with that class of patient who generally decides on a Sunday that he has not had any medicine lately, so promptly sets off to see "his doctor" and honour him with a visit.

What is the chief inducement to a man to join a club? His sick pay, his "death" money, and his medical man whom he "sweats." Let them have their sick pay and their pensions and their death money by all means, but let them pay for these things themselves and do not let the medical profession pay for them; they have their own pensions to provide for and how often are they able to do it? I believe that medical attendance is one of the biggest bribes that sick societies have to offer to their clients.

I also believe that the prime reason which enables clubs to dictate [illegible] cerning their own interests. Surely their own interests are plain enough in the club question. We are supposed to belong to a noble profession, but where does the nobility show itself in the eagerness with which one man takes what his next-door neighbour has refused on the grounds that the "labourer is worthy of his hire"?

I would suggest as a cure for all these injustices and grievances (almost if not quite the worst the medical profession has to contend against) that the General Medical Council or the British Medical Association, or better still both combined, should issue a fiat that "any medical man who accepts any club or contract practice at less than 10*s.* per head per annum, or the so much per visit and medicine system should be guilty of conduct infamous in a professional respect." I believe that the result of this would be that half the clubs in the kingdom would become bankrupt, but at any rate the social status of the medical profession would be raised and after all that is what is wanted most. Apologising for troubling you at such length,

I am, Sirs, yours faithfully,

Feb. 16th, 1904. ANTI CLUB.

"POE AND HIS MISUNDERSTOOD PERSONALITY."

Edgar Allen Poe, like De Quincey, Carlyle, and Wagner, is perpetually criticised as an author from the standpoint of his physical condition or personal habits. In the *Arena* of last month is an article, entitled, "Poe and his Misunderstood Personality," by Dr. William Lee Howard, who points out that Poe himself made the extraordinary discovery that his habits of intoxication were due to his psychopathic condition. Dr. Howard quotes a letter from Poe to G. W. Eveleth, written in 1848, in which Poe says: "But I am constitutionally sensitive—nervous in an unusual degree. I became insane with long intervals of horrible sanity. During these fits of absolute unconsciousness I drank—God only knows how often or how much. As a matter of course, my enemies *referred the insanity to the drink rather than the drink to the insanity*" Dr. Howard states that Poe here described a disease now recognised by neurologists as psychic epilepsy and no more under his control than is the epileptic attack so familiar to us all. Without following the author into a disquisition upon the various forms of disease and their etiology recognised under the name "dipsomania," we think that there is no doubt [illegible] literary work and to count for much in the high position—very high considering both the character and bulk of his work—that Poe enjoys in the literary world. It was his mental and moral instability that disturbed his calm power with riotous fancy and the blend has proved of extraordinary fascination to critical and imaginative palates. Despite his crude sensationalism Poe has always been an author's author.

PAYMENT OF MEDICAL WITNESSES.

To the Editors of THE LANCET.

SIRS,—Can an M.B., Ch.B., recover fees in medicine and surgery in a court of law

I am, Sirs, yours faithfully,

Feb. 20th, 1904. M.B., CH.B.

*** Yes.—ED. L.

"HIS MAJESTY'S HEAVIEST SUBJECT."

A CORRESPONDENT writes. "It is several years since I saw Mr. Thomas Longley who was known at Dover as His Majesty's heaviest subject, but the announcement of his death on Feb. 22nd has prompted me to send you a few particulars which will no doubt be of interest to your readers, especially in connexion with your recent annotation on the fat boy of Peckham (Jan 9th, p. 106) and the note from a correspondent on Daniel Lambert (Jan. 23rd, p. 207). In his youth I believe Mr. Longley did not greatly differ in his bodily proportions from the average, but at the time of his death he was said to be over six feet in height, to have measured 70 inches round the chest, an abdominal girth of 85 inches, and a calf 26 inches round. His weight was over 46 stones. If my memory serves me, his wife was below the average in stature and his son, though of stout proportions, showed no indication of going beyond the limits of normal growth. On the other hand, his daughter far exceeded the average build for her age. Visitors to the Star Inn, of which Mr. Longley was proprietor, could generally obtain a view of this big man through the open door of the parlour in which he was practically a prisoner, supporting his body on one chair while with another in front of him he supported his ponderous abdomen. He was extremely shy, however, of being looked upon as an exhibit but was exceedingly affable to those fortunate to obtain an introduction to him through the intermediary of a local resident. Enterprising showmen frequently made him handsome offers to become a member of their shows but they always met with a prompt though courteous refusal."

THE OLDER L.S.A.'S AND SURGICAL FEES.

To the Editors of THE LANCET.

SIRS,—A patient objects to the "exorbitant" amount (£10 10*s.*) of [illegible] fully [illegible]

1876.

*** We think that the full fee should be paid. But the question is a purely legal one, and we cannot guess how a county court judge might decide it.—ED. L.

THE TREATMENT OF HYPERCHLORHYDRIA AND ATONIC DILATATION OF THE STOMACH.

To the Editors of THE LANCET.

SIRS,—If you or any of your readers could advise me of literature dealing with this subject I would feel greatly obliged. Any medical man's personal experience on himself or a patient, with the prognosis, and especially with the opinion regarding the benefits of operation, would be inestimable.

I am, Sirs, yours faithfully,

Feb. 27th, 1904. F.R.C.S.

TEMPERATURE AND DREAMS.

A CORRESPONDENT sends us an account of his experiences as follows:—

> Has any connexion been shown to exist between the blood temperature and dreams? Perhaps my personal experience may not be devoid of interest. Recently I took a three days' rest in bed, starting with a temperature of 103° F. At this temperature I cannot dream at all. I have no control over the thought apparatus and merely obtain drowsy moments of perhaps ten minutes' duration in which all is chaos, yet pervaded by some one object which I cannot define. Let me call it a "brick." I cannot get away from that brick which conveys no fixed impression. At 102° things improve a little and perhaps there are two bricks. At 101° I cannot well remember what takes place, everything is so indefinite, but the bricks have disappeared.
>
> But at 99·5° (exactly) the fun begins. On closing my eyes and thinking *absolutely of nothing* in a short time living pictures appear, dim at first, but as the brain gets into working order

finally most vivid. I seem to be walking about amongst living men and women and observing all that they do; but it is not like a common dream in which you imagine you are a part of the scene and can experience joy or fear, &c. On the contrary, I know I am not really present but that it is as if my "astral body" were out "on his own," and I have to keep my *eyes closed* all the time as the moment I open them the vision disappears. Sometimes I am unnoticed among the crowd, at others people stare very hard and attempt to converse, but I can hear nothing nor can I address them—to do so or to open my eyes would bring me back in bed. If I get tired of one scene I can wander off to another and if I lose myself I open my eyes and immediately make a fresh start. Last night I met with some very unpleasant but still interesting individuals. As examples of deformities they were not to be beaten. Faces without features, for instance. Some people had hands and faces resembling polished Spanish mahogany but very much deformed. Once I actually revisited a former scene.

Now none of these visions represents any mental impressions formerly received. Some are common enough but others are so very extraordinary that it shows the brain is *creating* them. When the temperature falls to 99° my "astral body" has to remain in bed. I get no visions at all. As a *rule* I do not dream, or if I do I am unconscious of the fact in the morning, but these visions occur when I am *less* asleep than the usual dreaming stage and the recollection becomes more permanent.

HERMAPHRODITISM.

OUR contemporary *Mr. Punch* has unearthed the following delightful advertisement from the *Christian Advocate*:—

> GOVERNESS, JUNIOR; Intermediate; male and female.

There is no doubt about the intermediateness in this case.

PERSONAL RECOLLECTIONS OF SIR RICHARD OWEN.

A CORRESPONDENT sends us the following anecdotes of Sir Richard Owen:—

> While reading the other day a chapter on the aye-aye of Madagascar in "Mostly Mammals," by R. Lydekker, I was reminded of the late Sir Richard Owen. It was in the early sixties that I had occasion to confer with Professor Owen who was then curator of the Hunterian Museum; I met him in the College library and after discussing the matter in which we were both interested he at once entered upon the peculiarities of the aye aye, a specimen of which he had just then been examining, commenting in his fervid, earnest manner on the animal's large ears, prominent eyeballs, peculiar dentition, and attenuated middle fingers; in doing so he himself became quite a study in his enthusiasm and the abounding pleasure he experienced in making out and determining the history of the animal's habits, its method of obtaining its particular food, as illustrated by the means it possessed for effecting its purpose.
>
> Perhaps another reminiscence may not be out of place. At a dinner given to Sir Edwin Chadwick, the sanitary pioneer, Professor Owen narrated an anecdote of his younger days which may not be without interest now that the question of the London water-supply is to the fore. When occupied at Lancaster some old women of the town were in the habit of taking tea together at one another's houses in turn; part of the town was supplied with water from the river, which had several degrees of hardness, but a fresh source of soft water which came from the rocky hills had been adopted for other parts. In one of these latter districts a tea party was held at which the company was loud in the praise of the quality of the beverage; one of them, addressing the hostess, observed she must have put a power of tea in t' pot. "Na, na," she replied, "it's no t' tay that's ower good, it's t' watter."

A CASE OF VERONAL POISONING.

Dr. F. A. Philippi (Bad Salzschlirf) writes in regard to this case, which was described by Mr. G. Fernandez M. Clarke in THE LANCET of Jan. 23rd, p. 223, that veronal is stated to be a di-ethyl-malonyl compound of urea which is manufactured by E. Merck of Darmstadt who possesses some literature about this drug.

◆

Interested should procure a copy of the report of the Departmental Committee on the Use of Preservatives and Colouring Matters in the Preservation and Colouring of Food, published by Eyre and Spottiswoode, East Harding street, E C., 1901. The recommendations have not yet become part of the statute, although it is very desirable that they should be adopted.

M.B., F.R C.S.—We cannot publish so violent a tirade against the profession of which our correspondent is a member, but we quite admit that to a certain extent he is right and we will consider the possibility of treating the subject editorially.

Quassia will, in our opinion, be very wrong to set up in practice within the mile radius. He obtained his introductions presumably by working for his present principal and it would be distinctly unfair to set up against him.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

St. J[illegible]s HOSPITAL FOR DISEASES OF THE SKIN (Leicester square, W.C.)[illegible] 6.15 P.M. Dr. M. Dockrell: Herpetic Diseases. (Chesterfield Lecture.)

[illegible]

Tem[illegible]erature

NORTH-[illegible]AST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Dr. G. P. Chappel: The Early Signs and Symptoms of Phthisis.

FRIDAY (11th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. A. W. M. Robson: The Surgery of the Pancreas. (Hunterian Lecture.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—5 P.M. [illegible]

MEDICAL GRADUATES [illegible] W.C.).—4 P.M. Dr [illegible]

NATIONAL HOSPITAL [illegible] square Bloomsbury [illegible]

ROYAL INSTITUTION [illegible] 9 P.M. Prof. F. T. [illegible] (illustrated by experiment).

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd, 1904.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which a[illegible] sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., [illegible]re dealt w[illegible] by them? Subscriptions paid to London or to [illegible] than fo[illegible]gents (with none of whom have the Proprietors a[illegible]xion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

A Clinical Lecture

ON

THE TREATMENT OF CANCER OF THE BREAST BY OPERATION.

Delivered at King's College Hospital

BY W. WATSON CHEYNE, C.B., F.R.S., F.R.C.S. ENG.,

PROFESSOR OF CLINICAL SURGERY AT KING'S COLLEGE AND SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

GENTLEMEN,—You have of late seen a number of cases of cancer of the breast in which operations have been performed and as the operative procedure which has been adopted in these cases is a matter of great importance I propose to put before you some of the main points. You will have observed that in all cases the operation has been a very extensive one It is true that in some instances the disease itself was extensive, but in others the tumour in the breast has been comparatively small and nevertheless a large operation has been performed. Indeed, the extent of the operation has not been affected to any great degree by the amount of disease present, except in so far as the skin incisions are concerned or as the posterior triangle of the neck has been opened or not.

The modern operation which you see here is based on two fundamental principles, first, on the view that cancer is primarily a local disease and, secondly, on the removal of all probable lines along which it may spread whether visibly infected or not. The local *versus* the constitutional nature of cancer has been much debated and I need not discuss the matter here. Suffice it to say that the recent operative measures are founded on the belief that whatever may be the constitutional predisposition to the disease it actually commences in one spot and spreads from that over the rest of the body and that the aim of the operation must be not only to remove all visible disease but also to take away any invisible germs which may have become disseminated in the vicinity. On the view of the local origin of cancer it follows that if both the visible and the invisible disease are removed the patient should be freed from that particular attack and may never have any further trouble, although, of course, [illegible]ere is nothing in the operation to prevent him from having [illegible]resh outbreak in other epithelial tissues.

In former days surgeons were very undecided on this [illegible]estion and hence the operations were performed, so to [illegible]eak, in a half-hearted manner. Apart from that also the fear of sepsis and the want of knowledge of what we may call the anatomy of the disease rendered the old operation a very imperfect one according to our present ideas. Thus, if we go back, say, 50 years the operation laid down for cancer of the breast was a comparatively small and [illegible] prominent part of th[illegible]rous lump, was removed. [illegible] was extended to the axil[illegible] the axilla were taken away. The result of these operations was that, while a case occasionally remained well—and it is quite possible that some of these were not carcinoma at all, seeing that histological examinations were at that time in their infancy—the disease recurred within a short time in the vast majority of the patients and very frequently the recurrence took the form of numerous nodules scattered along the line of the scar and in its vicinity; and, further, the disease frequently progressed much more rapidly after operative interference than it was apparently doing before. Indeed, so much was the latter the case that in the more slowly growing forms, of which what is termed "atrophic cancer" is the type, it came to be laid down generally that operation was not permissible. It was pointed out that in these cases the patients might live for several years without operation, while, on the other hand, if an operation was performed recurrence would in all probability take place quickly and the progress of the disease would be much more rapid than it had been—in fact, the cancer would lose more or less its atrophic character. And in other forms of the disease even the most sanguine held that at the best operation added but a few months to the life of the patient, while some surgeons, such as Benedikt, were so discouraged by the results which they obtained, partly as regards the mortality after operation and partly as regards the constant recurrence of the disease, that they gave up operating on cancer of the breast altogether. While this was the general result of operation in these cases some surgeons who held that the disease was really a local one tried to obtain better results by enlarging the area of operative interference. Thus, Gross made a clean sweep of the whole of the prominent part of the breast with the skin over it and also to some extent of the axilla, often leaving a large wound which could not be closed afterwards by stitches but which had to heal by granulation. To some extent his procedure was justified by improved results.

For a long time the enlargement of the glands in the axilla was a point to which attention was not greatly paid. The chief reason for this was no doubt that in those days sepsis was very prevalent and that the opening up of the axilla was generally followed by diffuse suppuration in that region, while some also held that the enlargement of the glands in the axilla was not necessarily due to cancerous infection but might to some extent be inflammatory. Where the surgeon came to the conclusion that the enlargement of the axillary glands was due to actual infection with cancerous material the presence of this condition was usually regarded as a contra indication to operation. As regards the glands, the utmost that was done was to shell out any noticeably enlarged glands.

It was not till the end of the "sixties" that Lord Lister pointed out the possibility and the advisability of removing the axillary glands and fat in these cases by methodical dissection and under the protection of the antiseptic treatment. The operation as performed by Lord Lister from that time forward was a very free one compared with the old operation. He removed the skin much more extensively than was usually done and it was *chiefly with the view of* obtaining subsequent union of the edges in these operations that he elaborated his method of suturing wounds with button sutures, &c. He also made a point in most cases of stripping off the pectoral fascia and clearing the axilla in practically every case. His method remained the most complete up to recent times and has been followed by several other surgeons with marked improvement in results. As I saw almost all his later operations I became very much interested in the results and they certainly seemed to me to be a great advance on what was formerly obtained. Towards the end of the "eighties," however, I tried to trace as many of his private cases as I could and I was surprised and much disappointed to find that a large proportion had recurred either locally or internally, although the average prolongation of life was decidedly greater than formerly.

Up to this time what may be called the anatomy of cancer of the breast, and, indeed, the anatomy of the breast itself, was not really understood. These more extensive operations were done on the general idea that it was advisable to take as wide an area around the cancer as possible, but there was no precise knowledge as to the extent and direction of the possibly infected area, and it was not till the histological work of Heidenhain in Germany and of Stiles in Edinburgh was done that we knew with anything like precision what the state of matters was and what tissues must be removed in order to get rid of all possible disease. Before these researches were published this department of operative surgery was more or less haphazard and, while in some instances good results were obtained there was a total want of precision about the work. Heidenhain and Stiles, however, *showed* us the lines of spread of cancer of the breast, how it tended to run along the lymphatics in the suspensory ligaments to the skin, how the lymphatics in the pectoral fascia became affected, how intimately the pectoral fascia is associated with the pectoralis major muscle, how the infection spreads in the breast and axilla, how extensive the breast itself is, and how the removal of the prominent part of the breast in no way implies removal of the whole organ.

I had the opportunity of seeing Mr. Stiles's work before it was published and was so impressed by it that about the end of 1889 I began to put his results into practice in operative work. I soon found marked improvement as regards the question of local recurrence and in April, 1892, I read a paper at the Nottingham Medico-Chirurgical Society[1] calling attention to these new facts and indicating the nature of the operation which was required to apply them to practice. In 1894 Halsted,[2] who was working on the same lines, based more especially on Heidenhain's researches, also published a paper on this subject and his paper attracted more attention than mine; indeed, at that time he carried out the procedures in a still more thorough manner. This modern operation, founded on the researches of Heidenhain and Stiles, has now been adopted by many surgeons and it is this operation which you see carried out here.

I may now in a few words point out the essence of the modern operation. I will not go into details but I may recapitulate the essential points and these have reference chiefly to the method of dealing with the skin, with the fascia and muscles, and with the lymphatic glands and vessels.

1. *As regards the skin.*—The removal of the skin cannot be too free. None of the skin over the prominent part of the breast should be left behind and if the cancer is laterally situated irregular incisions must be made in that region so as not to approach the cancer closer than a couple of inches at least in any direction. Further, the incision must not be carried straight down to the muscle; it must gradually shelve away from the breast so that, for instance, in the case of the upper incision one should not in a fairly fat woman see the pectoral muscle till just below the clavicle. Unless this is done lobules of the breast will, as Stiles has shown, almost inevitably be left behind. I have never seen any sloughing of the edges of the skin follow even extensive undermining of the flaps and, in addition to the more thorough removal of the breast in this way, such undermining also increases the possibility of closing the wound after the operation is completed. As regards this last point, however, although in the great majority of cases by extensive undermining of the skin and by the use of strong silver wire tied as tightly as can be done I am able to bring the edges together, that is quite a secondary consideration and should not influence us with regard to the amount of skin removed, although it may be taken into account in planning the direction of the incisions

2 *The method of dealing with the pectoral fascia and the muscle.*—The pectoral fascia must be completely removed and a portion at least of the greater pectoral muscle should be taken away in all cases. The latter must be done for two reasons: in the first place the pectoral fascia is so intimately connected with the muscle, dipping in between the muscular bundles, that an attempt to separate the fascia from the muscle is very apt to lead to lymphatic vessels and also outlying lobules of the breast which might possibly be infected being left behind In addition, infected lymphatic vessels may be cut into and the cancer cells may thus be distributed over the surface of the wound. The second point of importance is that if a portion at any rate of the pectoral muscle is not taken away it is very difficult to clear out the axilla as thoroughly as ought to be done. The fascia over the serratus magnus where it is exposed in the axilla should also be taken away. As to the amount of the pectoral muscle that should be removed it is advisable to take away practically the whole of the sternal portion of the pectoralis major. At any rate it is essential to take away the lower portion coextensive with the prominent part of the breast so as to be sure of taking all the pectoral fascia beneath it. But if this is done the remainder of the sternal attachment is not of any particular use; its nerve supply will in all probability be injured, while its removal facilitates the clearance of the axilla very considerably and also gives a better chance of approximating the edges of the wound afterwards. As regards the clavicular portion I think it is but seldom that it need be taken away, for its removal does not materially help the clearance of the axilla, while I have never seen any reason to suppose that infection may spread from the sternal to the clavicular portions and I believe that it is of much value for the subsequent mobility of the arm. As regards the question of the pectoralis minor some surgeons always remove that muscle as well, and no doubt where there is much glandular infection it is well to do so, both because in that way more thorough access to the axilla is obtained and also because in those circumstances the nerve supply of the muscle is almost certain to be injured, in which case it is, of course, rendered useless. Where, however, the axillary glands are not much affected and where the nerve supply can be preserved I generally leave the pectoralis minor, because in these circumstances the space can be quite well cleared without taking it away.

3. *The lymphatic glands and vessels.*—All the glands and fat in the axilla should be removed in one mass along with the breast. The breast should not be taken away first lest in dividing the tissues infected glands or lymphatic vessels be opened and cancer cells be distributed over the wound. The direction of the various chains of glands must also be borne in mind and there are three groups to which special attention must be paid. In the first place we have those which follow the axillary vein and in regard to these I would particularly direct attention to the importance of lifting up the vein at the apex of the axilla and of removing the fat and glands which lie behind it. One not uncommonly finds enlarged glands hidden away behind the vein at the upper part and unless the vessel is lifted up and the tissue is removed from behind it the operation will be futile. The other two chief lines of spread are upwards in front of the vessels and nerves and also behind them, following the course of the nerve of Bell; in both of these directions the fat and glands must be thoroughly dealt with.

A very important question which arises is whether the fat and glands in the posterior triangle of the neck should also be removed, although not apparently infected, in all cases. Of course, if any enlarged glands are felt in that situation there can be no question that the space should be thoroughly cleared if the operation is performed at all, and I must say that I am becoming inclined to clear the supraclavicular space more often than I formerly did. Certainly if in clearing the axilla infected glands are found high up in any of the positions indicated the probability of commencing infection of glands above the clavicle is very considerable and in those circumstances I think that it is well to open the posterior triangle and to clear out the fat and glands at the root of the neck. This is quite essential where enlarged glands are found at the point where the vein passes out of the axilla. But any marked enlargement of the supraclavicular glands in my opinion renders the case inoperable from the point of view of radical removal. Halsted has also advocated in some cases following the glands down into the mediastinum. Personally, I have never done this and I doubt very much whether such a severe procedure is worth while. The cases where that would be necessary seem to me to come under the class of inoperable cases.

Such are the essential points of the operation as you see it carried out here and you will naturally ask, Are the results better than those which are obtained by a less severe operation and, if so, are they so much better as to justify the much greater severity of the procedure? With regard to the latter point the mortality after these operations is so slight that it may be practically disregarded. I have performed a large number of operations now and have only lost three patients; one of them at the time of the operation from ether and shock combined; one where the patient died suddenly ten days after the operation; and one from sepsis, where we found afterwards that my assistant had a small pustule on his finger which he did not know of at the time. Hence, from the point of view of mortality, the greater severity of the procedure is practically a matter of no moment and we are really only concerned with the relative value of the results obtained. These results must be considered from two points of view—namely, the prolongation of life and the question of recurrence

In my Harveian lectures on the Objects and Limits of Operations for Cancer, published in 1896, I gave a list of the cases on which I had operated on on the above lines and in a later paper, which appeared in THE LANCET[3] I not only brought these cases up to date but added a number of others, making the list up to 99 Since that time I have operated on a much larger number of patients, but it is unnecessary to make a further list because the results are apparently the same as those formerly obtained, and, as a matter of fact, what we want now to know is not so much the condition of the patient soon after the operation as the condition after the lapse of several years. As six years at least have elapsed since the operations on the patients in my last list were performed, we can obtain some information with regard to the latter point and I have attempted to trace these patients up to the present time. My list contained cases operated on both in private and at the hospital and, as regards the private patients, I have been able to trace all with one exception and have either been able to verify the results myself or have been informed of them by the medical attendant. As regards the hospital patients, such a large number cannot now be traced that they are useless from a statistical point of view and comparatively few have been verified either by myself or by a medical man. In a large city like London it is not surprising that the poor should be lost sight of in a number of years varying from six to 13. They do not remain long in one place and there is no particular reason why they should leave their addresses and the result is that a number of my letters have been returned marked "Gone away" or "Not known" It will, however, I think, suffice for all practical purposes if I use the private patients, all of whom I can trace with one exception. They give a very fair view of what may be expected from the radical operation after a long period of years.

[2] Annals of Surgery, vol. xx.

[3] THE LANCET, March 18th, 1899, p. 756.

Before going into the figures I may here state that in determining the cases to be operated on I make no selection from the point of view of getting good statistics. Hopeless cases have naturally been refused operation—that is to say, cases where from the local distribution of the disease it was clearly impossible to remove it or where internal deposits were undoubtedly present. But where there has seemed any chance of removing the disease, even though only a very poor one, the patient has been given the benefit of the doubt It will be seen from the lists published in the Harveian lectures and in THE LANCET as before mentioned that some of the cases were so nearly hopeless that if I had had the slightest regard for statistical results they would have been excluded, but as in several very unfavourable cases no recurrence has taken place after a considerable time I have not felt justified in refusing operation except in clearly hopeless cases.

Coming now to the statistical results in the list referred to 34 of the cases were private patients and were operated on in private and I have been able to trace them all with one exception. In these cases from six to 13 years have elapsed since the operation was performed.[4] The result is that at the present time 17[5] of these 34 cases are alive and well without any recurrence. In 14 cases[6] recurrence has taken place and 13 of these patients have now died from the disease Two patients have died from other troubles without any trace of recurrence having manifested itself; one (Case 51) died from pneumonia two years after the operation and one (Case 54) from heart disease seven years after the operation One patient (Case 55) cannot be traced. This gives 50 per cent. alive and well after periods varying from six to 13 years[7] or if we study the recurrences we have 58·8 per cent. in which there was no recurrence and 41 per cent. in which there was recurrence; or if we assume that the case lost sight of also recurred there are 44·1 per cent. of recurrences; or, to make the result still more definite, as the future of the two cases which died is uncertain as regards ultimate recurrence, we may say that we know the exact facts in 31 cases and of these 17, or 54 8 per cent., are alive and well and 14, or 45·2 per cent. have recurred.

Thus, in whatever way we work out the figures we get the result that from 50 to 55 per cent. of the cases in which this operation has been performed are alive and well after periods varying from six to 13 years. This gives a very fair estimate of the final results of the modern operation as applied to all cases except those in which it is obviously impossible to remove all the existing disease. I have no doubt that had I aimed at getting the best statistical results and selected the cases from that point of view a decidedly better percentage would have been obtained; but I do not think that such a selection is fair to a patient suffering from such an inevitably fatal disease as cancer of the breast, more especially as in this instance the mortality after operation is quite insignificant. The question of selection of cases for operation is totally different where the cancer is situated in regions where the mortality from the operation is considerable and where it increases with the extent of the disease. In such circumstances the question must be whether the probability of non-recurrence is sufficiently great to justify the risk which the patient runs, but in these instances, where the question of operative mortality may be practically ignored, I do not think that such selection is justifiable. Besides, it is impossible to prophesy the result as regards recurrence after operation. Several cases which seemed limited and small and which I looked on most hopefully have recurred, while others which I thought were practically hopeless have shown no further sign of disease.

Thus, taking this list of private patients, had I been selecting them with an eye to statistical results I would probably have excluded 11 (two of these, indeed, were practically hopeless from the first—namely, Cases 35 and 84). Nevertheless, of these 11 cases four have remained free from disease—namely, Case 27 for ten years, Case 35 for nine and a half years, Case 72 for seven and a half years, and Case 54 who died from heart disease after seven years without any sign of recurrence. From a practical point of view, however, it is interesting to attempt to separate the cases into groups and we may take two sets of groups—namely, (1) according to the apparent rapidity of the growth; and (2) according to the extent of the disease at the time of the operation.

1. In the first group, looked at from the apparent rapidity of growth, we have two classes: (*a*) Slow-growing cancers. In this group we probably have Nos. 6, 14, 39, 55, 59, 67, 71, and 88—eight cases, of which six remained well, one recurred, and one has been lost sight of. Assuming that the latter recurred, we have 75 per cent. in this group remaining well and 25 per cent. recurring. (*b*) More rapidly growing cancers. Here we have a list of 26 cases, 13 of which remained well and 13 recurred, giving 50 per cent. each way.

2. A more useful grouping is according to the extent of the disease at the time of the operation: (*a*) Small tumour in the breast with moderate infection of the axilla. Here we have Cases 5, 6, 11, 39, 50, 53, 55, 59, 61, 67, 71, 74, 76, 82, 87, 88, 90, 94, and 98—that is to say, 19 cases of which 13 have remained well, five have recurred and one has been lost sight of; thus, 68 4 per cent. certainly remain well and probably 31·6 per cent. have recurred. (*b*) Marked infection of the axillary glands. These include Cases 14, 27, 33, 35, 37, 51, 54, 72, 83, 86, 96, 97, and 99—that is to say, 13 cases of which six, or 46 per cent., have not recurred and seven, or 54 per cent., have recurred. (*c*) Cases where the supraclavicular glands were distinctly enlarged at the time of the operation. These were two in number—namely Cases 36 and 81—and in both of these recurrence took place. This last division is a most useful one and gives a fair idea of the result of the modern operation. It shows that the earlier and more limited the cancer the greater the chances of success; but it also shows that there is no possibility of prophesying in any individual case, for, on the one hand, in the most favourable cases recurrence may take place when the disease has apparently been widely removed, while in other cases which seemed unfavourable the patients remain well. This no doubt depends on various circumstances which have led, on the one hand, to an early and wide dissemination of the disease and, on the other hand, to marked local growth without dissemination. What these circumstances are it is most difficult to say. Cancers vary very much in their virulence, some having a great tendency to rapid dissemination and growth, such as the florid cancers of the breast, while others grow and disseminate with extreme slowness, such as the typical atrophic scirrhus, and there is every degree between these two extremes. This may be due to the existence of different kinds of cancer or, on the other hand, to varying tendencies in the body to cellular growth. The early dissemination may also be due to accidental circumstances, such as handling the growth, blows, &c, which force the cells into the vessels and thus lead to early dissemination in cases where the disease is otherwise apparently small and limited.

It is interesting to note the seat of recurrences in the first group. In No 11 the recurrence appeared in the internal organs about six and a half years after the operation, and later in the form of nodules in the skin and various parts of the body. In Case 53 the recurrence took place in the abdomen and was evident in less than two years. In Case 76 a thickening appeared about two years later in the other breast and afterwards there were nodules in the skin. The disease in the other breast may have been, of course, a fresh development. The patient was still alive in July, 1903. In Case 90 the recurrence was quite rapid and occurred especially in the thorax and liver and the patient died 11 months after the operation. In Case 98 the patient had an attack of pleurisy (? cancerous) about two and a half years after the operation and subsequently developed intense pain in the spine followed by paralysis and she ultimately died; there was no local recurrence. As regards the third group, although it only contained two cases it confirms the conclusion which I have come to—namely, that when the supraclavicular glands are infected the chances of arresting the disease are extremely slight; in fact, if at all marked, especially if the disease is noticeable towards the anterior part of the root of the neck, the chances are, I believe, practically *nil.*

---

[4] The numbers of these cases in the former lists are 5 6, 11, 14, 27, 33, 35, 36, 37, 39, 50 51 53 54, 55, 59 61, 67, 71, 72, 74, 76, 82, 83 84, 86 87, 88 90 94, 96, 97 98 and 99. (See Harveian lectures, 1896, and THE LANCET, March 18th, 1899 p. 756)

[5] Nos 5, 6 27, 35, 39 50 59 61 67 71, 72 74, 82, 83 87 88, and 94.

[6] Nos. 11, 14, 33 36 37 53, 76, 84, 86, 90, 96 97, 98, and 99

[7] Of these cases 2 are alive after 13 years, 1 after ten years, 2 between nine and ten years, 3 between eight and nine years, 6 between seven and eight years, and 3 between six and seven years.

The most striking fact with regard to these cases is the great rarity of a second operation and, indeed, in the above list in only three instances was a second operation performed. This is my experience not only in these cases but in the whole of my work. Instead of, as used to be the case formerly, a second operation being performed after a few months or a year in a very considerable number of instances it is quite rarely that I operate for recurrence and that for two reasons. In the first place, in cases really favourable for operation recurrence in the area of the operation wound—that is to say, in the breast or the axilla—is quite a rarity. As a rule when recurrence takes place in these cases it is either in the supraclavicular glands or in the bones or in some internal organ, and almost the only secondary operations I have performed have been done with the view of removing enlarged glands from the posterior triangle of the neck. In the second place, where recurrence has taken place in the region of the operation it has been in bad cases and there has been evident disease elsewhere and therefore operation for the removal of such recurrences would be futile; indeed, in the few instances where nodules have appeared on the side of the chest this has not as a rule been the first place where recurrence was noticed. Most usually internal recurrences, more especially intrathoracic disease, have been observed before anything was apparent on the external surface and then the nodules in the skin and subcutaneous tissues have come as a more or less sudden eruption. In these circumstances they have seemed to me to be not so much an indication of local deposits left behind at the time of the operation as a generalised eruption secondary to the internal recurrence.

As to the date of recurrences I only know approximately the time at which attention was drawn to them, which, of course, is not the time at which the fresh disease began to grow. As would be expected, where the recurrences are not local a longer time will elapse before the recurrence becomes evident than where it is the result of disease left behind in the area of the operation and in the cases where recurrence has taken place there has evidently been a considerable gain in the length of life over the old operation. One very interesting point is the lateness of the recurrence in several instances. The longest case of late recurrence which I have had was one in which I did a free operation before I began following the definite lines of Stiles's and Heidenhain's researches. In that case the patient turned up at the hospital some 13 years after the operation with numerous large glands in the posterior triangle of the neck. She stated that she was quite well till about six months previously when she had a bad attack of influenza and that subsequently to that the glands above the clavicle began to enlarge. I did not operate on her and therefore cannot assert positively that these were cancerous glands, but I have not the slightest doubt in my own mind that they were so from the clinical appearances.

In the cases in this list there are two distinct instances of late recurrence—namely, Case 11, where the disease appeared about six years after the operation, apparently about the sternum and mediastinum, and Case 14, where the disease appeared about seven years after the operation in the glands of the neck. In these instances there can be no doubt that the cancer cells were present in the glands, &c., at the time that the operation was performed and they must have either been lying dormant for some time afterwards or else have been growing extremely slowly. In Case 14 the cancer approximated closely to the atrophic form of scirrhus and therefore the growth may have been steady but very slow, but in the other cases this was not so. The cancer was a much more rapidly growing form and it seems to me that in that instance the growth of the cells must have been more or less arrested for a time after the operation. In several other cases where the cancer was growing rapidly at the time of the operation and where I have expected rapid recurrence an interval of two or three years has elapsed before this has taken place and I cannot but think that the cancer cells in these cases must have grown more slowly, if at all for a time, after the operation than they were doing before it. In more than one instance the reappearance of the disease followed an illness, such as influenza, which left the patient in a weak state of health.

From a study of the recurrences after the modern operation I have come to the conclusion either (1) that cancer in its early stage in a healthy body grows extremely slowly and that it is only in the later stages, when the resistance of the body is broken down, that the more rapid growth occurs; or, on the other hand, (2) that the extensive modern operation in some way or other exerts an inhibitory growth on cancer cells which are left behind in the vicinity. It is quite conceivable that a combination of these two explanations may be correct. Thus, where only two or three cancer cells are present in the body of the patient with good resistance they may take a long time to acquire a firm hold and not till the body resistance is broken down either by intercurrent illness or by toxæmia from the products of the cancer cells themselves does the growth become more rapid. Hence operation, by removing the cancerous masses which are lowering the body resistance by their products, may render it difficult for the few cells that are left behind to start fresh growth. From this point of view the difference in the rapidity of recurrence after the modern and after the old operation may be solely dependent on the amount of disease left behind in the two cases. In many instances in the old operation collections of considerable size are left behind and recurrence is rapid; whereas in the modern operation presumably any cells which are left behind in the vicinity are very few in number and local recurrence is slow. In the matter of internal recurrence there is no marked difference in the two cases. In that instance in all probability the internal deposits, although not yet producing symptoms, are of sufficient size to be more or less independent of the resisting power of the body.

In some instances, however, it appears as if the cancer cells must have lain dormant for a time after the operation. In that case, apart from the removal of the mass which is poisoning the body and thus allowing the resistance of the body to be improved, it is conceivable that the modern operation may influence local deposits left behind in other ways. As the result of the procedure lymph channels are extensively removed and the lymph flow is arrested or slowed through the part and thus the distribution and nutrition of any cancer cells left behind may be much interfered with. The vascular arrangements are also much altered and nerves are extensively divided. As regards the latter point, Mr. G. L. Cheatle has shown some very interesting photographs which seem to indicate a certain relation between nerve supply and the growth of cancer. They especially indicate a greater tendency for the disease to spread along the area of the particular nerve distribution in which it first occurred rather than indefinitely into neighbouring nerve areas. In this operation the trophic nerve influence must be profoundly altered in the area of the operation and this may be of some unknown importance.

I think that we may now form a fairly final judgment with regard to the treatment of cancer of the breast by operation. We may say, for example, that taking the average of all cases operated on, favourable or otherwise, something like 50 per cent. will remain well for a number of years and in those cases in which the tumour is small and well limited and the glandular infection is slight the proportion of successes will be considerably greater. We may also say that where recurrence takes place it is most usually internally and the suffering of the patient is less than if no operation had been performed, while life is considerably prolonged: and that these results are due to the more precise and extensive removal of all possibly infected areas—the breast, the skin, the pectoral fascia, the muscles, the glands, &c.—in the modern operation, and also, and this is very important, to the fact that the cancerous deposits are not cut into at the time of the operation and the cells thereby distributed through the tissue. Again, we may conclude that cancer is a local disease at its commencement and if only all the existing disease can be got rid of there is no reason for any further development from the primary focus. It is purely a question at the time of the operation of getting beyond all the disease. Recurrences, both general and local, are the result of direct spread from the original ocus Epithelial growths cannot originate in the lymphatic lands or other non-epithelial structures; the cancer cells re the direct progeny of cells in the original tumour. At he same time I do think there is a greater tendency to ancer in one individual than in another and that, for xample, the formation of cancer in one breast after removal f the other for the same disease may just as likely be a resh development altogether as a growth secondary to the riginal tumour. I have seen cylindrical epithelioma appear n the rectum in a patient whose tongue had been successully excised for a squamous epithelioma five years previously. have seen a rodent ulcer occur after a successful operation or cancer of the breast, and so on, and I must say I believe n the existence of a general tendency to cancerous developnent. But even if this be the case and the patient may me day develop another cancer elsewhere that is no argunent against the removal of the original disease as comletely as possible, seeing that it may be many years, if at ll, before any fresh trouble arises and that, on the other and, if the original disease is left or only partially taken way the life of the patient must be comparatively short. bove all things remember that in the *first* operation lies the atient's only chance and that it must therefore be done with the greatest thoroughness, however limited the disease nay be at the time of the operation

ABSTRACT OF

The Hunterian Lectures

ON

THE EVOLUTION AND ACTION OF CERTAIN MUSCULAR STRUCTURES OF THE HEART.

Delivered before the Royal College of Surgeons of England on Feb. 22nd, 24th, and 26th, 1904,

BY ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, LECTURER ON ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.

LECTURE III.[1]

Delivered on Feb. 26th.

CLOSURE OF THE FORAMEN OVALE.

MR. PRESIDENT AND GENTLEMEN.—The impression given on reading an account of fœtal circulation is that the right auricle is a passive, open chamber through which the blood of the superior vena cava passes to the right ventricle and that of the inferior vena cava flows through the foramen ovale into the left auricle. The active contraction of the limbic muscular bands which make up the annulus ovalis is not taken into account (Fig. 12). Since only about one-third of the blood from the right ventricle passes through the lungs before birth and thus reaches the left auricle at least twothirds of the blood must reach the left ventricle by the foramen ovale. Before birth the auricles are surrounded by the solid unyielding lungs and are filled by being actively dilated through the contraction of the ventricles, for there is then no respiratory pump. At the commencement of auricular systole the limbic bands which seize the termination of the inferior vena cava, by compressing and drawing that vessel towards the foramen ovale, pump the pure arterial or placental blood into the left side of the heart. With the first descent of the diaphragm the action of the limbic bands is altered. The termination of the inferior vena cava, firmly fixed in the diaphragm, is drawn down by that muscle and the plane on which the limbic bands act becomes more vertical in direction. Their origin in the inter-auricular septum is drawn towards the vena cava, thus helping to close the foramen ovale (*Fig. 12*). The fall of pressure in the right ventricle and the rise of pressure in the left auricle are the other conditions which lead to closure of the foramen ovale.

FIG 12.

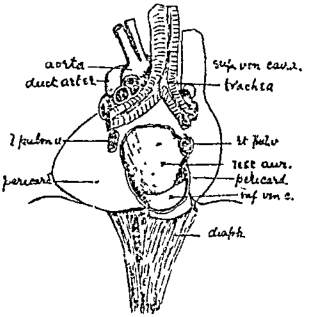
CLOSURE OF THE DUCTUS ARTERIOSUS.

As a rule nothing is said in accounts of the fœtal circulation of the mechanism which brings about the closure of the ductus arteriosus. With the first breath two forces come into operation which lead to its obliteration. When a section is made across the aorta and ductus near their point of union (Fig 13) it is seen that the wall of the ductus is round in outline and projects within the aorta, giving the lumen of that vessel a crescentic shape From that appearance one may infer that the pressure within the pulmonary artery is greater than that within the aorta before birth, and the fact that the wall of the right ventricle is then thicker than that of the left points to this being so. At birth, owing to the opening up of the pulmonary circulation and the closure of the foramen ovale, the pressure in the aorta becomes twice that, or more, in the ductus arteriosus, with the result that the wall of the aorta now bulges outwards and projects within the lumen of the

FIG. 13.



The heart and great vessels of a full-time child exposed on their posterior aspect. The wall of the ductus anteriosus is seen to project within the lumen of the aorta ductus arteriosus, thus blocking the flow through that vessel. The diaphragm also plays a part. Before birth the ductus arteriosus is on a level with the arch of the aorta; after birth it ascends obliquely to reach that vessel. The ductus arteriosus arises within the apex of the pericardium and passes to the arch of the aorta. With the descent of the diaphragm the whole pericardium and its contents are drawn downwards. The arch of the aorta, on the other hand, is bound to the neck by the carotid sheaths and cervical fascia. Hence a strain is thrown on the ductus which assists in retarding the flow of blood through it.

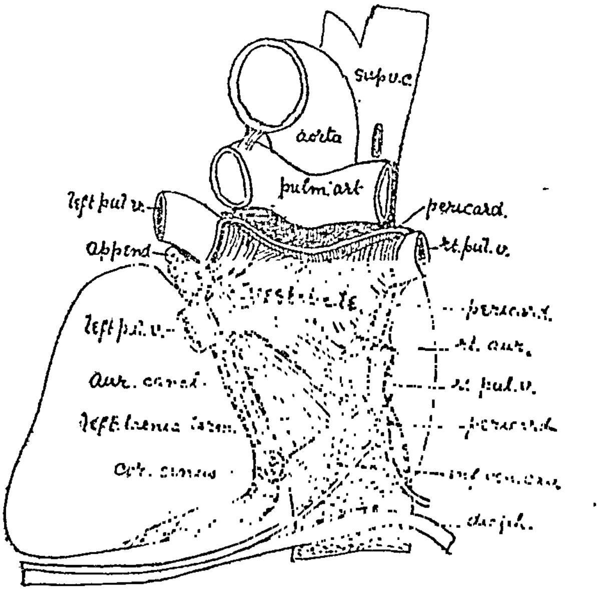
---

[1] Lectures I. and II. were published in THE LANCET of Feb. 27th (p. 555) and March 5th (p 629), 1904, respectively.

CONSTITUTION OF THE LEFT AURICLE.

In the human left auricle is to be seen the climax of a transformation which has led to the partial suppression of the auricle proper by the growth of a new part—the vestibule. The vestibule is shown in Fig. 14; it is that part of the left auricle into which the pulmonary veins pour their blood and which is demarcated from the rest of the auricle by the strong muscular band already described as the left tænia terminalis. At an early stage of development the left auricle, like the right, consists of two parts, an auricular canal and the auricle proper; there is then no vestibule. The septum between the two auricles is derived by an inflection of the auricular canal. The lungs occupy the dorsal or spinal part of the body cavity, the heart the ventral or sternal. The pulmonary veins issue from the lungs and join to form a single trunk which passes forwards to pierce the auricular canal. To the right of its orifice is the septum, to its left a band of muscle representing the tænia terminalis which in the amphibians and reptiles helps to close the orifice of the vein during auricular systole and which we may suppose acts in a similar manner in the human embryo. In the course of development the heart sinks backwards between the lungs and the lungs grow forwards over the heart, thus altering completely the relationship of the pulmonary veins to the heart. The pulmonary veins are pulled right and left, their common termination in the auricle separates, and their orifices move apart. Then the upper and lower veins of the same side separate and move apart. As the venous orifices separate the musculature of the auricular canal grows over and fills the intervals of separation and in this way the vestibule of the left heart is produced and ultimately comes to lie behind the right auricle and to form by far the largest part of the left (Fig. 14). The left tænia terminalis is drawn outwards from the septum and forms a horseshoe band that surrounds the vestibule (Fig. 14). Every stage in the development of the vestibule of the human heart can be seen in a permanent form by a study of the hearts of reptiles, birds, and mammals. The auricle proper, which is so large in the right chamber, is reduced to the mere appendix in the left. The auricular canal from which the vestibule was developed is surrounded by annular fibres which lie hid in the auriculo-ventricular groove. Thus the left auricle consists of vestibule, auricular canal, and auricle proper.

FIG. 14.



Heart dissected from behind to show the parts of the left auricle. The attachments of the pericardium to the heart are represented. It will be seen that the termination of the inferior vena cava acts as a fulcrum for the musculature of the left auricle.

CLOSURE OF THE PULMONARY VEINS.

The left auricle is suspended between the roots of the lungs (Fig. 15). As the pulmonary veins enter the pericardium they are surrounded by circular fibres continuous with, and derived from, the musculature of the vestibule (Fig. 14). Besides these circular fibres, which act as sphincters to the pulmonary orifices, the left tænia terminalis plays a leading part in preventing regurgitation of blood. Rising from the termination of the superior vena cava, where it is continuous with the corresponding band of the right side, it passes to the left, looping round the vestibule and termination of the pulmonary veins to end in the inter-auricular septum and auricular canal. In systole it sinks within the auricle and covers the orifices of the pulmonary veins. It becomes greatly hypertrophied in the early stages of mitral stenosis.

FIG. 15.

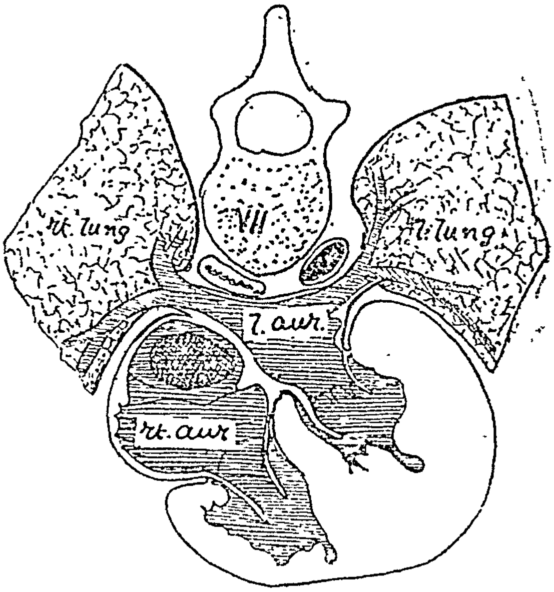


Diagram to show the relationship of the left auricle to the roots of the lungs. A transverse section at the level of the seventh dorsal vertebra is represented.

THE DIFFERENT EFFECT OF MITRAL INCOMPETENCE AND MITRAL STENOSIS ON THE PULMONARY VEINS.

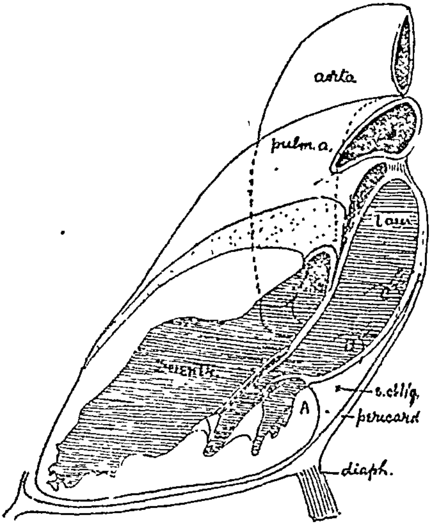
No fact is better recognised than that the train of symptoms which follows mitral stenosis differs from those that follow mitral incompetence. The difficulty in explaining the cause of the difference lies in a loose conception of the manner and time in which the pulmonary orifices are closed. In mitral stenosis the highest pressure within the auricle occurs during systole of the chamber when the pulmonary orifices are closed or, in case of dilatation from back pressure, partially closed; in mitral incompetence the highest pressure occurs when the walls of the auricle are relaxed in diastole and when the pulmonary orifices stand wide open, so that the ventricular wave of pressure may spread right within the venous system of the lung. The widespread character of mitral regurgitant bruits is probably due to their diffusion in the veins.

CONTRACTION OF THE LEFT AURICLE.

In systole the anterior wall of the left auricle comes into apposition with the posterior wall and the cavity of the vestibule is reduced to a slit. In studying the manner in which this is produced one has to take into account the relationships of the auricle (Figs. 15 and 16). Behind, it is in contact with the œsophagus and aorta in the posterior mediastinum and spinal column, unyielding structures which prevent any forward movement of the posterior wall.

In front of it are the commencement of the aorta and right auricle, both of which are drawn backwards in auricular systole and come forwards again in diastole. When the auricle contracts the posterior part of the base of the left ventricle is drawn upwards and occupies the room vacated by the auricle (Fig. 16). The manner in which that movement is produced may be understood from a reference to Fig. 14, which shows the left auricle in a position of semi-contraction. The annular fibres which surround the neck of the left auricle rise within the inter-auricular septum and pass to the left in front of, and behind, the auricle to meet and to turn up on the appendix. When they contract the neck of the auricle is greatly contracted and pulled inwards and upwards to the inter auricular septum, carrying in the same direction the base of the left ventricle. The vestibule, it will be observed, is firmly fixed to the termination of the inferior vena cava, which serves as a fulcrum for its musculature (Fig. 14); its right and left extremities are held by the pulmonary veins; its upper border is bound by a reflection of pericardium to the fibrous tissue below the arch of the aorta. Hence in systole of the auricle its walls converge upwards and to the right towards the fixed points just enumerated. As the auricle contracts the base of the left ventricle is drawn upwards to occupy its vacated space and thus receives its load. The auricle, because it is fixed by the venous terminations, cannot move to the ventricle, so the base of the ventricle moves to the auricle. When the thorax is opened and the lungs collapse the left auricle loses its pulmonary supports and its muscular mechanism is thus upset.

FIG. 16.



Vertical section of the heart (hardened *in situ*) laying open the left side. The left auricle is dilated from a stenosis of the mitral orifice. A, Posterior base of the left ventricle. B, The position of a normal base in diastole of the auricle. C, The position of a normal base in systole of the auricle.

DIASTOLE OF THE LEFT AURICLE AND PRODUCTION OF ITS NEGATIVE PRESSURE.

In systole of the ventricle its posterior base moves downwards and brings about an active dilatation of the left auricle (Fig. 16). With the outflow of blood into the aorta the arch of that vessel is unbent somewhat and its ascending part springs forwards, thus helping to increase the size of the auricule [illegible] pulmonary artery [illegible] that in the aorta from 140 to 180 millimetres I found that the ascending aorta came forwards 8 millimetres. The descent of the base of the left ventricle is due to (1) the fibres which rising at the apex of the heart ascend straight on the diaphragmatic or posterior surface of the left ventricle to end on the membranous ring at the auriculo-ventricular orifice; (2) to the columnar layer on the inner surface of the heart which runs on the lateral wall of the ventricle from apex to the membranous ring at the base; and (3) to the musculi papillares. All these act from the apex as a fixed point.

THE EFFECT OF PERICARDITIS ON MOVEMENTS OF THE LEFT AURICLE.

In order to allow its movements to take place freely and without friction the anterior wall of the left auricle is separated from the aorta and pulmonary artery by the transverse sinus (Fig. 17), while the posterior has inserted between it and the pericardium a serous diverticulum, the sinus obliquus (Fig. 16). In pericarditis adhesions are very apt to occur between the walls of the left auricle and the surrounding structures, with the result that the movements of the auricle and the power to produce a negative pressure within their cavities is partly or completely lost.

FIG. 17.

[illegible] auricle to the aorta.

MOVEMENT AND FUNCTION OF THE AURICULAR APPENDICES.

In late stages of heart disease when the auricles become greatly dilated the appendix of the right auricle, very rarely that of the left, is found filled and distended by an ante-mortem clot. The contraction of the appendix constitutes the final act of the auricular systole. The base of the appendix moves nearer the centre of the auricle so that its mouth lies over the auriculo-ventricular orifice at the end of auricular systole. The systolic retraction of the right appendix is brought about by a special retractor band which, rising from the tænia terminalis internal to the superior caval orifice, branches out within [illegible] the appendix. The left appendix, which [illegible] the whole of the proper [illegible] is drawn inwards by a band which springs from the left tænia terminalis. The contraction of the appendices completes the loading of the ventricles. When the auricles become permanently distended the ventricles are filled in the initial stage of the auricular systole, so that the appendices get no opportunity of discharging their load. Dr. James Mackenzie regards the clot in the appendix as a result of paralysis of the auricle.

FIXATION OF THE APEX OF THE HEART.

The apex of the heart is the least moved part of the ventricles during systole. It becomes then a functionally fixed point from which the musculature of the ventricles may act on the auricles. In reptiles the cardiac apex is fixed by a ligament, but in birds and mammals this end is accomplished by the peculiar structure of the left ventricle.

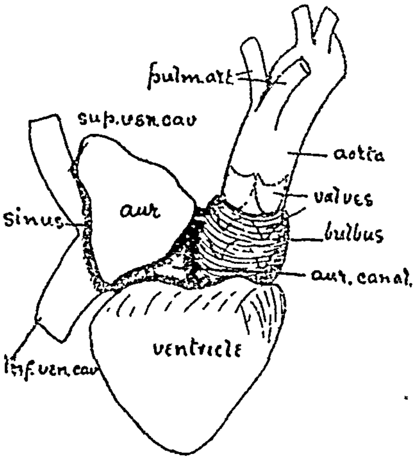
Those who have examined the thickness of the wall of the normal left ventricle must have been struck by its thinness at the apex (from two to three millimetres) and thickness at the base (from 12 to 15 millimetres) and marvelled why rupture of the apex is not more common than it is (Fig. 17). The muscular fibres at the base, owing to the wide calibre, act at a disadvantage in emptying the ventricle and therefore are increased in number, but the difference between the diameter of the base and apex will not account for the great difference in the thickness and arrangement of their muscular coats. In the wall of the left ventricle of all mammals the three layers of muscle described by Henle can be recognised. They are the outer longitudinal, the inner longitudinal, and the great middle "driving" layer of circular or spiral fibres. Of the bundles of spiral fibres no more need be said than this, that they pass in their oblique course from the outer to the inner surface of the ventricular wall and that each layer runs at a slightly different angle to the one deeper to it. In the superficial longitudinal fibres there are two distinct sets and both rise in the vortex at the apex (Fig. 17). One set runs straight upwards on the diaphragmatic surface of the left ventricle to end in the membranous ring at the base. The other passes spirally on the anterior surface to end chiefly on the base of the aorta, but some end by passing into the septum at the anterior interventricular groove. The inner longitudinal fibres begin in the reticular meshwork of the apex and like the outer longitudinal fibres, those on the septal wall end in the aortic orifice, while those in the lateral and posterior wall, including the musculi papillares, end in the membranous ring at the base. In systole the apex becomes the seat at which two forces act in opposite directions. While the thick layer of circular fibres in the basal part would drive it outwards, the longitudinal fibres act in the opposite direction and draw it inwards. The two forces are equally balanced in expelling the ventricular column of blood and hence the comparatively stationary position of the apex. While the longitudinal fibres that end in the root of the aorta act mainly on the apex as restraining fibres (for the slightness of the shortening from the apex to the origin of the aorta in systole is an observation in which physiologists agree) the fibres which pass to the base of the ventricles use the apex as a fulcrum from which they draw forwards the lateral and posterior base of the left ventricle.

On looking over the specimens of rupture of the left ventricle in the London Hospital College Museum I found they were of two distinct classes—one due to a localised thrombosis of the coronary artery which may occur at any point, the other class being greatly dilated hearts in which the rupture had occurred at the apical vortex. The region of the apical vortex is apparently contracted at an early stage of the systole in the healthy heart, otherwise it could not withstand the high systolic pressure, but in greatly dilated hearts it apparently closes later and has to withstand a higher ventricular pressure and hence becomes the seat of rupture.

THE MANNER IN WHICH THE PULMONARY VALVES ARE RENDERED COMPETENT.

It has been shown that there is still a remnant of the musculature of the sinus venosus in the right auricle of man but there is also a remnant round the base of the pulmonary artery of the musculature of that fourth chamber of the heart known as the bulbus arteriosus. In Fig. 18 is shown the bulbus arteriosus of a child who lived for some weeks which is in every way similar to that found in many fishes. The circular muscle fibres surround the common aortic stem in which the pulmonary artery and aorta are still unseparated, and within the bulbus are rows of valves with three well-marked semilunar valves at the summit (Fig. 18). Normally, the bulbus arteriosus is divided to form the roots of the aorta and pulmonary artery, but while its musculature, as shown in Borns's models, disappears from the aorta it remains as loops which encircle the terminal part of the infundibulum of the right ventricle and take their fixed origin from the base of the aorta. In all vertebrates the competency of the semilunar valves depends on this musculature.

FIG. 18.



Heart of a child showing retention of the bulbus arteriosus (from a specimen in the London Hospital Medical College Museum).

The great development of the bulbus arteriosus in gill-breathing vertebrates is due to the peculiar nature of their circulation. The heart is primarily a respiratory pump; the ventricle throws its load into the short aorta leading to the gills. To be able to receive the ventricular load and to force it onwards, that vessel is endowed with enormous elasticity so that no valves situated within it could be mechanically competent were they not furnished with a muscular or elastic support, such as is provided by the bulbus arteriosus. The musculature of the bulbus like that of the aorta is always in action but most so in *diastole* of the ventricle. In every way the pulmonary artery resembles the short gill aorta of fishes of which it is the functional representative in air-breathing vertebrates. The elasticity of the aorta has a definite limit; once the pressure is raised to from 120 to 130 mm. Hg the physiological limits of its expansibility are reached, but with the pulmonary artery it is different; it goes on increasing in size with every increment of pressure up to about 60 mm. Hg. The elasticity of the pulmonary artery becomes partially lost in emphysema. The pulmonary artery of amphibious mammals is enormous and capable of storing up many ventricular discharges. Dr. E. A. Gibson proved years ago that the pulmonary valves of the human heart received their competency from the musculature of the infundibulum.[2] The fibres of the bulbus arteriosus in lower vertebrates are not truly discharging but regulating fibres that maintain their tonicity when the true fibres of the ventricle have passed into a state of diastole. As far as one can tell with the naked eye this seems to be also the case in the mammalian heart. They probably play a part in the much discussed question of functional systolic bruits at the pulmonary orifice. When the right heart is distended the circular fibres round the base of the pulmonary artery form a functional stricture at the commencement of ventricular systole between the infundibulum and greatly dilated artery and are a factor which must be considered in explaining the production of pulmonary systolic bruits.

THE CLOSURE OF THE INTERVENTRICULAR FORAMEN.

In cases of congenital pulmonary stenosis, the commonest of all congenital diseases of the heart, or in those where the infundibular part of the right ventricle has never been functionally opened up, the interventricular foramen stands widely open. In birds and mammals it becomes closed whenever the foramen ovale is opened up. In the human embryo it is closed early in the second month, its disappearance being due to the development of a great band of musculature which is characteristic of the mammalian right ventricle and of which no notice has been taken (Fig. 19, B.). The relationship of this band to the interventricular foramen, or, rather to the membranous space which marks the position of that opening, is shown in Fig. 19. When the septal wall of the infundibulum of the right ventricle is examined there will be observed a raised wide flat band of muscular fibres which end in the base of the aorta (Fig. 19, A). That band is well known in the reptilia in which it is attached above to the septum between the orifices of the aorta and pulmonary artery. In a manner which need not be described it separates the arterial from the venous blood during systole of the reptilian ventricles. The great muscular band which first appears in the mammalian ventricle is shown cut across near its origin in Fig. 19, B. It is part of the inner system of the musculature of the right ventricle which bends inwards to reach the base of the aorta and fuses at its origin with the flat band on the infundibular septum (Fig. 19, A). From that origin it proceeds on the lateral wall of the right ventricle towards the right border of the heart, but its main branches run along the base of the ventricle, on the lateral margin of the right auriculo-ventricular orifice. In systole of the ventricle it helps to draw the lateral against the septal wall of the ventricle and forms a part of the safety-valve mechanism of the tricuspid orifice. The relationship of this band to the interventricular orifice will be observed. In systole the margin of the band falls right across the opening and closes it. In abnormal hearts showing congenital pulmonary stenosis this band is either absent or it has failed to join the septal band.

In conclusion, I should like to say that I have sought to show that the Hunterian method of using structure to interpret function and of using physiological knowledge to interpret structure is the most profitable of anatomical methods. If much advantage has followed the complete separation of anatomy and physiology much harm has also been done by this divorce which can only be remedied by a restoration of former relationships. No description of the anatomy of the heart can be considered satisfactory unless it can show the meaning of the structure of that organ. The key to the form and arrangement of the parts of the heart is a proper understanding of a wide principle which affects all mammalian hearts—namely, that they are so constructed that the ventricular systole may be utilised to fill the auricles.

TROPICAL DISEASES.—At a meeting of the West India Committee held at 15, Seething-lane, E.C., on March 8th, the Duke of Marlborough presiding, a paper on the Disease Problem in the West Indies was read by Sir Patrick Manson who said that the list of West Indian diseases included all the diseases of Europe with some two or three dozen tropical diseases He suggested that a well-equipped laboratory with an able and experienced director with suitable assistance should be established at some central and otherwise suitable point in the West Indies and also that every boy and girl in every school in the West Indian colonies should be taught the leading facts on which a rational system of tropical sanitation might be founded. All that was required was a short course of instruction to the teachers, together with a few diagrams and two or three additional pages in the current school-books. He felt sure that if these suggestions were carried out incalculable benefit would result to the West Indies in a few years.

Presidential Address

ON

THE CONGENITAL ORIGIN OF HERNIA.

Delivered before the Medical Society of Victoria, Australia, on Jan 6th, 1904,

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,

SURGEON TO THE ALFRED HOSPITAL, MELBOURNE.

GENTLEMEN,—Considerable latitude is by custom accorded to the retiring president in his choice of a subject for the annual address. I propose to deal with a subject which I would entitle "The Congenital Origin of Hernia" and as it is my intention that this address shall fall into series with various papers that I have published on the subject of hernia during the last five years I must ask your permission very briefly to epitomise the views I have already expressed on the subject. At the Brisbane Congress of 1899 in a paper on the Etiology and Treatment of Inguinal Hernia in the Young[1] the following conclusions were arrived at: 1. Oblique inguinal hernia is invariably caused by the presence of a congenital sac which in the vast majority of cases is provided by patency of the whole or a portion of the processus vaginalis. 2. There is no evidence in favour of the view that congenital weakness of the abdominal wall in the inguinal region is a factor in the causation of inguinal hernia. 3. While actual weakness of the abdominal wall in the inguinal region is frequently met with and may be an occasional cause of recurrence after operation, such weakness is not congenital but is an acquired weakness due to the existence of the hernia during a lengthened period. 4. Complete removal of the sac when performed before the abdominal wall has sustained such damage will not be followed by recurrence; it is furthermore the only treatment which is in the true sense curative. 5. It follows from the foregoing that the use of a truss (except in the case of very young infants) is an improper method of treatment and that the only permissible course to advocate for every case of hernia in a child is operative removal of the sac—the sole cause of the hernia.

Three years later, at the Hobart Congress of 1902 I was enabled to produce a [illegible] short, perhaps, of being quite [illegible] congenital origin of femoral hernia;[2] I then felt that with a little close scrutiny we might possibly gain some information as to direct inguinal hernia, that would at once resolve our doubts and enable us to place it in the same category with the oblique inguinal and the femoral varieties and regard it as being due to the presence of a congenital sac internal to the epigastric artery. This expectation has been at least partly realised, for I have here [illegible] which I am indebted to Professo [illegible] sac associated with an open pro [illegible] was taken from the body of a man who had never been the subject of hernia. My own belief is that such a pouch would be found to be always antecedent to the occurrence of direct hernia. I will supplement the evidence I adduced at the Hobart Congress of 1902 in favour of the congenital origin of femoral hernia by some additional facts which will render it impossible any longer to regard it as other than absolutely conclusively proved. My method of investigation has been exceedingly simple; it has consisted merely in looking at hernial sacs after their removal by operation and I purpose to narrate in detail the appearances observed which [illegible] afford instructive information as to the nature [illegible]

[illegible] lesson the case of a boy, aged nine years, with a somewhat large hydrocele of the cord on the left side, who came under my care at the Children's Hospital in May, 1900 On close examination I found that I was able to diminish the volume of the swelling somewhat by manipulation and I concluded that there must be a small opening of communication with the general peritoneal cavity. I removed the sac of the hydrocele and on examining the specimen which is depicted in Fig. 1 this is what I found. Above there was an exceedingly narrow communication with the abdominal peritoneum through which the peritoneal fluid was enabled to percolate but far too small to permit the escape of any portion of bowel. The remarkable sacculated outline of the bag should be noted and also that one of the sacculations has become completely closed over, forming a cyst. The whole sac is, of course, obviously congenital; it is a portion of the funicular process. The sacculations are also obviously congenital, for it can hardly be suggested that they could have been caused by pressure from within even were the cyst not present to give an absolute denial to such a view. It is rare to find an inguinal sac with this secondary sacculation so well marked but it is still more rare to find one without some more or less distinct diverticula. Sometimes inspection will reveal only one or two irregular contractions of the serous surface. On the other hand, the sacculation, either single or multiple, may assume any form, occupy any position, and be of any size.

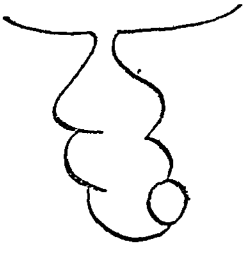
FIG. 1.



Sac of hydrocele showing sacculation.

I have selected this case for consideration in the first instance because it is free from certain factors that might have become the subject of debate and doubt in a case in which hernia had been present. It is impossible to over-estimate the importance of this observation as to the liability of the congenital sac to display a certain amount of sacculation. You are perhaps a little puzzled at my insistence on this point, for I am not aware that attention has been called to it at all prominently before this evening. It is true that these appearances have been noted and occasionally alluded to, but the real significance and the far-reaching influence of this secondary sacculation do not seem to have occurred to observers who have usually ascribed it quite erroneously to the results of localised inflammation. Nevertheless, it is not merely of fundamental importance to the correct understanding of hernia, it is the very alphabet of the subject. For just as we have already seen that the cause of hernia is the presence of a sac, so I shall endeavour to show that all the multitudinous varieties of inguinal hernia owe their origin to corresponding varieties of sacculation of the sac. This being so, it becomes a matter of great importance to inquire as to the cause of this sacculation, and in order to do this we must go back to the embryological period at which the sac is formed. Further, for reasons that will appear, we shall do well in the first instance to direct our attention to the study of the femoral sac, from which we shall gather information which will enable us the more readily to fathom the somewhat intricate problems associated with the varieties of inguinal hernia. At an early period of embryonic development the three primary layers of the embryo become arranged in the manner depicted diagrammatically in Fig. 2. Ventrally two main layers are formed, the splanchnopleure closing in the primitive alimentary canal and the somatopleure constituting the body wall. Between these two layers is situate the primitive pleuro-peritoneal cavity lined throughout with mesodermic tissue, on the inner surface of which a layer of cells, flattened and stratified, will ultimately become specialised as the endothelial structure of the peritoneum. During the second month bud-like projections are extruded from the surface of the body wall which are the rudiments of the four limbs. These buds are projections of the whole thickness of the body wall and it may quite probably be a normal event for a pouch of peritoneum to be included in the bud (Fig. 2, D) to become subsequently obliterated. Whether this inclusion of a pouch of peritoneum is a normal event or whether it is a developmental accident matters not at all. That which does concern us is the fact that such a pouch of peritoneum is not only often formed but that it often persists; further, that it may occur in more than one situation in the limb but that its most frequent seat is in the immediate vicinity of the main vessels and is the future crural canal. This peritoneal pouch having been formed at a very early period it becomes a matter of extreme interest to trace its destiny and to see how it will fare during the period of rapid changes associated with the developing limb. There is a method of studying the finer processes of embryonic development which is peculiarly helpful to us in this matter, for it must be confessed that the knowledge we are enabled to gather from the skilled examination of embryos at varying periods would unaided be of scarcely sufficiently fine texture to enable us to predict the probable future of so minute an embryological structure as this peritoneal sac. Such knowledge may, however, sometimes be usefully supplemented by a process of inductive reasoning from observation of the distribution of blood-vessels and nerves. I need not elaborate this principle here, as I have already drawn attention to it in a previous article,[3] but I will at once invite your attention to a consideration of the branches of the common femoral artery which run upwards on to the abdominal wall, the superficial epigastric and circumflex iliac vessels, and the superior and inferior external pudics. The explanation of the somewhat retrograde course pursued by these little vessels becomes very evident if we refer to the first beginnings of a vascular system in the embryonic limb bud. The first branches that are given off from the main vessel of the limb bud will be apportioned to structures that are destined to form part of the abdominal wall, so that when in the course of development the groin becomes deepened and the limb undergoes changes that are to fit it to straighten out it will at once be seen how it comes about that the superficial epigastric artery and its fellows follow the course they do. A little twig passing directly upwards will ultimately become the superficial epigastric, another with a slightly outward tendency will become the circumflex iliac, and one or two passing somewhat inwards the external pudics.

FIG. 2.

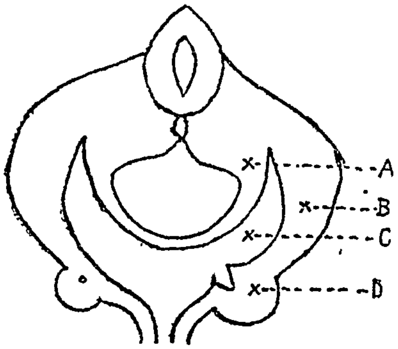


Diagram of embryo. A, Somatopleure. B, Splanchnopleure. C, Primitive pleuro-peritoneal cavity. D, Limb bud with hernial sac.

And now that we have arrived at a conclusion as to the causes that have determined the course of the branches of the common femoral it would seem reasonable to expect that a contemporaneous peritoneal sac occupying a similar position in the evolving limb should in response to the same developmental influences incur a like fate, so that a sac which is of sufficient length and suitably disposed at its inception would assume a position similar to that of the epigastric artery; another in like manner will display an outward and upward direction like the circumflex iliac, while yet another will follow a course corresponding to that of the external pudics; and this is exactly what we find. It is impossible to look at Fig. 3, which represents the branches of the femoral artery on one side and the favourite positions assumed by femoral sacs on the other, without being impressed with the conviction that the developmental influences which determine the course of the arteries on the one hand and the position of the hernial sacs the other are [illegible]. The three upper sacs depicted in Fig. 3 have all come under my personal observation during the last three years. I venture to assert that any material enlargement of a femoral sac as the result of the presence of hernia is impossible and I would also venture to formulate the following law of hernia—viz., *the variations observed in the clinical manifestations of hernia are mainly determined by the size and position of the sac.*

---

[3] Ibid.

FIG. 3.

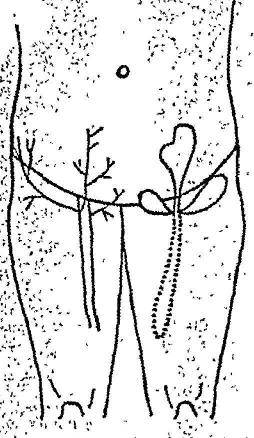

Diagram showing on the *right side* the *femoral artery* and its branches and on the left side the favourite seats of femoral sacs. That shown passing downwards is extremely rare (see Macready, Treatise on Ruptures).

[Mr. Russell went on to say that even in small femoral sacs there was evidence of their congenital origin. He continued:]

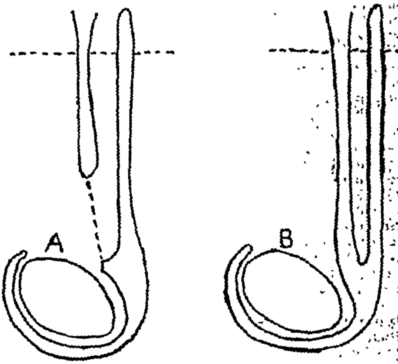
I shall have to refer to the relationship between the course of the blood-vessels in the fully formed body and the processes of embryological development which determined their disposition. A similar relationship must, of course, exist between the branches which, by repeated multiplication, dwindle to the smallest arterial ramifications and the evolutions of the parts to which they are distributed; only here the processes in question become too rapid and *too minute* for detection by the eye of embryological research, so that the vascular arrangements supply the only available *record* we possess of their nature. Now, it would be remarkable if these mesodermic evolutions, which are finally mapped out for us in the tortuosities of the arterial branches, should leave no mark upon the sac which is subject to the same vicissitudes, and we should expect to find some permanent record of their incidence in the shape of irregularities of the sac wall or sacculi. Here, again, our expectations have been abundantly realised. Of all the femoral sacs that I have removed during the last three years in every one has secondary sacculation been not merely evident but exceedingly marked; I should be interested to see a femoral sac devoid of sacculation of this kind. This evidence appears to me to be quite conclusive, but I would point out that apart from these various points that I have alluded to the mere inspection of the tissue of a femoral sac with eyes that are alert would convince us that it is a congenital structure. It is a thick structure lined, it is true, with endothelium continuous with that of the peritoneum, but comprising in addition a quantity of [illegible] muscle, fibrous tissue, and fat. In fact, I have no hesitation in saying that if we really look at an ordinary femoral sac now that these various features of it have been pointed out we shall only wonder that the truth about femoral hernia should have lain hidden so long and that it should ever have been thought that femoral hernia was an acquired form of the affection

I turn now to a branch of the subject which surpasses in interest that which we have been considering and enter upon an examination of the different varieties of inguinal hernia. Of these there are a whole cluster of which the great majority (all excepting one, in fact) are produced by developmental variations in the formation of the processus vaginalis. I have classified the varieties of inguinal hernia in the accompanying table and you will notice that under the heading of *funicular varieties* of hernia I place the commoner oblique forms and in addition the infantile, interstitial, and properitoneal forms.

Congenital inguinal hernia.	Funicular.	Simple—total and partial funicular hernia.
		Sacculated—interstitial, properitoneal, and *infantile*.
	Non-funicular—direct inguinal hernia.	
Acquired inguinal hernia.	Probably not existent (? direct hernia *sometimes*).	

In order to understand how these numerous varieties of inguinal hernia take their origin it becomes necessary to cast back once more to the developmental period. The events which result in the formation of the processus vaginalis have not been observed with any exactness but certain things are abundantly evident and these are sufficient for our practical purposes. The chief one is that in its extension from the primitive pleuro-peritoneal cavity to the scrotum the funicular process is subject to accidents of a special kind. Between the abdominal cavity, on the one hand, and the scrotum on the other it has, as it were, to run the gauntlet of the very actively developing abdominal wall. There is then a liability to the occurrence of a process of sacculation analogous to that about which I have already said a good deal in speaking of femoral hernia and of which the evidences in the inguinal region are most abundant. Here (Fig. 4, A) is diagrammatically represented an interesting example of the way in which the funicular process is liable to be "caught" by the abdominal wall in the process of development. It is the case of a man on whom I operated for left inguinal hernia in the Alfred Hospital. On making the usual incision in the groin I at once found myself in the tunica vaginalis which was arranged as depicted in the diagram. At one point the descending process of peritoneum had simply been implicated by the muscles of the abdominal wall during development, so that the descent of the testis had caused it to be drawn out into this long bag. On incising the further wall of the tunica vaginalis an ordinary hernial sac was found behind it which was removed in the usual way. How this arrangement has come about as the result of a developmental accident to the processus vaginalis will be readily understood from the diagram. If we mentally restore the portion of the processus vaginalis that has been obliterated so that we see that structure as it was originally it will be at once seen what has occurred (Fig. 4, B). A portion of the descending peritoneal sac has been caught and fixed by the developing abdominal wall and it has so happened that the hung-up portion was at a sufficient distance from the testis to permit of the normal descent of that

FIG. 4.



A, Diagram of condition found at operation, the hernial sac lying behind the tunica vaginalis. B, Diagram showing developmental condition before processus vaginalis is partly obliterated.

They are not applied tightly but merely laid on so as to get the exact size of the limb. The cast is removed while still wet. The best plan of removal of the outside plaster cast is to split it down the front by a vertical incision slightly to the outer side and then horizontally across the front of the ankle-joint. The edges are then fitted together again, the incision thus being closed, and the whole is consolidated by a final plaster of Paris bandage applied after removal. The cast thus taken should be about a quarter of an inch thick. From the cast a model is made in solid plaster and on this the leather casings are modelled. It is impossible, of course, to mould dry leather on the plaster so that it will keep its shape, but the difficulty is surmounted by soaking the leather in water. The only difficulty I have met with in this country is getting suitable leather. English leather does not seem to be nearly so pliable on soaking or to set so well on drying as the continental leather.

In order to make sure that the leather casings are strong enough, especially in the case of adults, thin steel bands are imbedded in the leather. These bands are first fastened securely on the plaster model, then on moulding the leather above them they leave an impress on the casing, so that on removal the bands may be riveted in their exact position in the leather. One band must always strengthen the thigh-piece below the tuber ischii. The holes for the escape of perspiration are punched from within out. The lateral supports are jointed at the knee but the joint is fitted with a peg screw, so that, if desirable, it may be immobilised.

By means of this splint the patient in nearly every case of fracture of the leg can be made to walk, with or without the aid of a stick, at the end of a week. Case 2 was one of the worst cases of Pott's fracture it was possible to meet, where the swelling and ecchymosis were so great that the posterior surface of the limb is still ecchymosed as high as the middle of the thigh now a month after his accident. If this splint can be applied to so severe a case of fracture any case can be treated with it. The bone is united well and the patient's joints, knee and ankle, are no longer stiff, as they would have been had they been kept at rest during the whole time he was in bed with a splint on or had plaster of Paris been applied to the limb. The advantage of this splint, in enabling a man to get up out of bed, to walk about, and even to go to business at the end of a week or ten days, must be very obvious. In cases of fracture of the femur also in old people where it is essential that they should not be kept in the recumbent position with a long splint on, this appliance will enable them to be got out of bed, and the tendency to hypostatic congestion of the lungs and bed-sore is thereby counteracted. The case of fractured femur shown above was one of fracture of the middle of the thigh bone, but this splint is also applicable to fractures of the lower and upper extremities of the femur. This splint was made for me by Mr. Hoefftcke, 21, Woodstock-street, London, W., who has modified and considerably improved Hessing's appliance.

Wimpole-street, W.

AN INQUIRY INTO THE SOURCE OF SCARLATINAL INFECTION AND ITS BEARING UPON HOSPITAL TREATMENT.[1]

BY R. E. LAUDER, F.R.C.S. EDIN., D.P.H.,

MEDICAL OFFICER OF HEALTH OF THE COUNTY BOROUGH AND PORT OF SOUTHAMPTON; MEDICAL SUPERINTENDENT OF THE BOROUGH AND PORT FEVER HOSPITAL.

MY first duty is to thank you for this opportunity of bringing before the Southampton Medical Society for its serious consideration a subject of much medical and public importance. The conclusions at which I have arrived are not altogether in accordance with those usually accepted and as a public official I look upon this society as the only competent tribunal in the borough to discuss and to decide the points at issue. As, moreover, the patients of everyone here form the basis of my remarks and deductions you will further be able to express an opinion as to the accuracy of the statistics and details I place before you. To this end I have sent to each medical practitioner a list of the cases notified by him during the past year and marked those which had been discharged from the isolation hospital and considered responsible for "return" cases. Gentlemen also who have notified cases of scarlet fever and are not members of this society have been invited to attend and if unable to do so have been asked to communicate any observations they might desire to make on cases which have been discharged from hospital and which are likely to be considered responsible for "return" cases.

The value of isolation hospitals from a public health point of view has recently been a subject of discussion both in the medical press and at the conferences of medical officers of health, and while it is true our knowledge of the infective process is not such as to preclude the possibility of mistakes, yet the observations of those controlling large hospitals and areas must help towards the solution of the problem. The difficulties of an isolation hospital present themselves, by universal opinion, very especially in scarlet fever wards. It is about scarlet fever that the greatest uncertainty exists and this uncertainty has led some experienced officers to demand the abolition of centred hospitals. In making this demand, however, a very important question has been largely ignored—viz., the question of internal administration. Before we can decide whether isolation hospitals are a failure or not we must ask ourselves whether our administration is such that the isolation principle has been properly tested.

In February last I altered my methods of administration and I propose now to sketch shortly the new procedure adopted, with the results obtained since that date. Our isolation hospital is for the use of the whole area of Southampton, in addition to being a refuge for the port sanitary authority, and during the past 12 months a sufficient number of cases of scarlet fever has been admitted and discharged to form a reasonable judgment of the value of the altered methods. The new methods are due to a firm belief, based on observation, that more classification and more segregation are essential and, moreover, that "return" cases are attributable not to the peeling condition, as is generally contended, but mainly to undetected discharges from the respiratory passages and ears in those who have left the hospital. The value of ordinary personal observation in arriving at this belief is enhanced when we bring into review our want of knowledge of the specific organisms and our present ignorance of where and when infection ceases. My observations, extending over a wide range of cases, have led me to regard the upper respiratory passages, particularly the naso-pharynx and the pharyngeal and faucial tonsils, as responsible for the reception and propagation of the infection.

It is not the purpose of this paper to discuss questions of pathological anatomy but a review of the anatomical peculiarities of the upper respiratory tract is essential in considering the feasibility of my contentions. The structure of this region, moreover, shows the possibilities that exist of long-continued infection and may of itself throw light on this obscure problem. I presume, therefore, to remind you very briefly of the more salient points. The nasal passages in the living subject present a very different picture from that viewed in the bony framework, owing to the thick mucous membrane which covers it, causing a narrowing of the openings of the different sinuses and nasal duct. The mucous membrane is thickest over the middle and inferior turbinates and covered by ciliated columnar epithelium with goblet cells on a delicate basement membrane and extends into the various air cells, communicating with the nasal fossæ. The tunica propria is composed of white fibrous tissue, rich in leucocytes and traversed by a venous plexus. Numerous compound racemose mucous glands open on the surface and between them there is much lymphoid tissue sometimes accumulated into nodules. In the air cells the tunica propria is very thin and sparingly supplied with glands. The following sinuses communicate more or less directly with the nose: the antrum, the frontal sinus, the anterior, middle, and posterior ethmoidal and sphenoidal cells, as well as the nasal duct, while the Eustachian tube connects the naso pharynx with the middle ear. The patency of all these communications depends for our purpose on a healthy condition of the mucous membrane. The mucous membrane lining the accessory sinuses is thin and pale and, with the exception of the frontal sinus, the drainage of these cavities, owing to their openings not being placed near the bottom, depends on the healthy and efficient ciliary action of their epithelium.

---

[1] A paper read as the annual address before the Southampton Medical Society on Jan. 20th, 1904.

The naso- and oro-pharynx, including the tonsils, present points of first importance. Here, again, the mucous membrane is rich in lymphoid tissue; particularly is this so at the vault and across the back of the pharynx on a level with the hard palate where it forms the pharyngeal tonsils. The mucous glands are very numerous and the surface down to the level of the hard palate is covered with columnar ciliated epithelium. The faucial tonsils are substantially masses of lymph nodules with numerous irregular depressions, into the bottom of which mucous glands open. We have here an extensive surface of glandular tissue richly supplied with vascular and lymphatic vessels, the main functions—outside the special senses—of the nose and tonsils being to purify, to warm, and to moisten the air inspired. It is not difficult thus to appreciate the possibilities offered by the upper respiratory tract for the reception, cultivation, and dissemination of specific micro organisms.

Independent of adenoids and enlarged tonsils so common in children it is easy to realise how, with our rapidly varying climatic conditions, a modification in the mucous membrane of the upper respiratory tract can be produced suitable for the reception, development, and manifestation of the specific microbe of an infectious disease. Again, the glandular tissues and the accessory sinuses may afford conditions favourable to the continued existence of this specific poison —conditions which may be sometimes [illegible] impossible [illegible] parent, may [illegible] membrane [illegible] jected and [illegible] more or less degeneration and shedding of the epithelium. An increase in the severity of this process may present many phases up to that of ulceration or sloughing. In the very simplest variety one can readily realise that a patient who has run a favourable course may be sent from hospital with one or more follicles distended with infective secretion, the virus being probably in an attenuated condition, which, under conditions such as catarrh, may discharge and infect a surface ripe for its cultivation, often leading to rhinorrhœa or middle-ear disease and invariably causing a "return" case. In the more severe cases accompanied by marked proliferation of adenoid tissue and altered secretions the probability of spreading infection is recognised not only while discharges continue but for a considerable period after they have ceased, being in proportion to the abnormal conditions set up in the mucous membrane and the implication of the tonsils and accessory sinuses.

The fact that prolonged stay in hospital or the absence of desquamation does not assist in preventing "return" cases gives support to the potentialities of the upper respiratory tract as being the focus of infection. This is indicated by the following clinical observations. 1. The class—young persons—which is most susceptible to scarlet fever is also most subject to abnormal conditions of the tissues of the naso-pharynx and the tonsillar region These tissues, consisting as they do of a large amount of lymphoid tissues with involutions of the mucous membrane, offer a most favourable nidus. 2 The period of incubation is short and the changes in the mucous membrane of the upper respiratory tract appear early. 3. Evidence of infection following operation on the upper respiratory tract 4. The constitutional symptoms and fever are, as a rule, in proportion to the condition of the respiratory passages. 5. The great majority of "return" cases is associated with discharges coming from the upper respiratory passages and ears. 6 Enlarged glands are in proportion to the crowding of the ward and the introduction of fresh acute cases.

Previously to February of last year the method employed here was that I believe in almost universal practice, of treating all cases in the general wards until such time as peeling and discharges had ceased. Patients were then disinfected by being passed in the ordinary way through the out-bathing station. Under this system complications of the fever in our wards were both common and obstinate. Nor is it difficult to postulate a reason for this. In such conditions the respiratory passages, healthy or otherwise, were kept continually within a zone of active infection, an infection, moreover, not necessarily confined to that peculiar to scarlet fever. The method now adopted aims at the protection of mild and convalescent cases by segregating them from those which are received in an acute state or are suffering from discharges. These mild and convalescent cases are thus, as far as possible, guarded against reinfection and their respiratory passages are assisted to free themselves naturally from the organisms of infection.

The following is a brief account of the methods adopted in our hospital. The cases are brought to the hospital from only one house at a time. On arrival each patient is examined before removal from the ambulance by the resident medical officer and a swab is taken from the throat for bacteriological examination. Doubtful cases are put into an observation ward and detained or sent home according to whether scarlet fever is found to be present or absent, the ward being disinfected immediately after their removal. Undoubted cases of scarlet fever are put into an "acute room" and kept there until the acute stage of the disease has passed and a bacteriological examination of the swab has excluded diphtheria They are then removed into the general ward where the recent cases are kept apart from those that are convalescent. These precautions are taken even with the mildest cases. If at any time aural or nasal discharges, enlarged tonsils, glands, &c., develop the patient is removed from the general ward to a pavilion or block reserved for such complications. At the end of the third week of the disease, if free from complications, the patients are transferred from the general ward to another pavilion which has been thoroughly disinfected and to which no cases are admitted except through the out-bathing station with the same precautions as if they were being discharged from hospital. They are kept in this pavilion apart from all other patients for one week, the nose, ears, and throat being carefully douched with a disinfectant each evening after bathing. At the end of the week—that is, the end of the fourth week of the disease—they are discharged from hospital after again passing through the out-bathing station, no matter what the condition with regard to the peeling may be. After their discharge no patients are admitted into the same pavilion until it has been thoroughly disinfected. The general wards are thoroughly disinfected at least once a month or as indicated by the condition of the patients. These methods have not only comparatively freed us from the occurrence of albuminuria, enlarged glands, discharges from the nose and ears, &c, in the patients, but have reduced the duration of fever and the period during which they had to be kept in bed, and left us during the year without a single case of post-scarlatinal diphtheria or relapse. Further benefit would, I believe, result from the complete and continued separation of each individual case.

I wish now to put before you in tabular form the results of carrying out the methods I have shortly described. The cases dealt with in the tables I lay before you have, as I have already mentioned, been submitted to each medical practitioner who notified. In this way each member has it in his power to challenge, if he has any grounds for doing so, the accuracy of the figures. The statistics of results obtained under the different methods are given in Table I. During 1902 no cases were discharged from hospital until all peeling had ceased, but during 1903 I have acted on the belief that the infection is in the respiratory tract, that the constitutional condition and particularly the rash are only the result of toxic products, and that therefore the desquamation of skin is not *per se* a source of danger.

TABLE I.

Year.	Cases notified.	Removed *to* hospital.	Discharged *from* hospital.	Average period in hospital (days).	Number causing "return" cases.	Cases treated at home.
1902 ...	261	208	164	48	7	53
1903 ...	427	353	325	34	7	74

In Table I. a contrast under various headings of the work of 1902 and 1903 will be found. You will notice at once that the total number notified in 1903 exceeds that of 1902 by 166; you will further observe that in 1902 the average period of detention in hospital was 48 days, while in 1903 it was 34 days—a reduction of 14 days. Notwithstanding this reduction in the period of hospital treatment the number causing "return" cases is in each period the same—viz., seven—and this works out in 1902 as 4·27 per cent. and in

1903 as 2·15 per cent. So that the percentage after 48 days' treatment was greater considerably than the percentage after 34 days, showing clearly, as far as statistics for such a period can show, that the longer period of detention with the associated causes did not remove, but rather increased, the possibility of the patient carrying away infection.

In Table II. a further analysis of the 325 cases discharged from the hospital during the year will be found :—

TABLE II.

—	Dis-charged.	Average duration in hospital (days).	Number causing "return" cases.
1. Without peeling or complications	33	33	0
2. Peeling without complications	204	28	2
3. Cases with complications ...	88	50	5
Total	325	34	7

I have arranged this table so as to illustrate the length of time each class was detained in hospital and also the number in each group that could possibly be held responsible for "return" cases. In the first group, limited to 33, and dismissed after 33 days' residence, without either peeling or complications, we received no "return" cases. The second group—those peeling but without complications—includes the great majority of cases treated. There were 204 in this group dismissed after an average of 28 days' treatment. None of those 204 had suffered from complications during their stay in hospital and at the time of their leaving no symptoms of any discharge were apparent. This large class was responsible for two patients to whom "return" cases were due. The details of these cases I will submit further on. The third group, in which complications of various kinds had occurred, numbered 88. These were detained an average of 50 days in hospital. This group produced the largest number of "return" cases—five—the particulars of which I will also submit to you. The second class of cases in the table—204 in number—were followed to their homes, being visited there daily for ten days This method was adopted so as to preclude the slightest possibility of even a mild case occurring without detection The conditions, also, to which these patients returned were carefully investigated, as their surroundings had considerable bearing on the probable spread of infection. Few, if any, of the cases could have been satisfactorily isolated at their own homes The statistics show that the 204 cases returned to 180 houses. These houses had an average accommodation of five or six rooms and contained 744 persons who had never suffered from scarlet fever. Of these, 363 persons were under 15 years of age, 36 were between 15 and 18 years, and the remainder—or 345—were over 18 years. If, therefore, peeling *per se* were infectious these 204 cases were returned to the very conditions under which the infection was likely to spread Of the "return" cases notified the following are the details of the two in Group 2 of Table II.

CASE 1.—The patient, a girl, aged eight years, was discharged after 29 days' treatment and while still peeling Eight days after leaving the hospital she was found to be suffering from a discharge from the nose. A brother and sister of the patient developed all the symptoms of scarlet fever five days later i e, on the thirteenth day after the patient had left hospital In this case it is probable that the specific organism still remained in an attenuated condition and was rekindled into activity by the condition causing the catarrh.

CASE 2—The patient, a girl, aged three years, was discharged after 24 days' isolation, peeling A sister developed scarlet fever three days later. The former case received seven days' special treatment in the same room as another patient who had suffered from discharges until three days before admission into the special ward. In this case probably the specific organisms remained in unhealthy tissues which ceased to give outward evidence of their presence

So that in the two cases of this group responsible for "return" cases there were other possible sources of infection present, and considering the total number—204—followed by only two "return" cases it is not illogical or unreasonable to say that the desquamation played no part in the result. Of the five "return" cases under Class 3 of Table II. the following briefly are the details.

CASE 3.—The patient, aged four years, was in hospital 54 days; no peeling on discharge. Suffered from nasal and aural discharges; nasal discharge returned on the day after leaving hospital. A servant was notified as suffering from scarlet fever ten days after the patient's return home.

CASE 4.—The patient, aged six years, was in hospital 44 days; no peeling or discharge on leaving hospital; had had aural discharge. A brother was notified seven days after the patient's return home.

CASE 5.—The patient, aged seven years, was in hospital 31 days; peeling; had watery discharge from the nose. A brother was notified as suffering from scarlet fever eight days after the patient's return home.

CASE 6—The patient, aged four years, was in hospital 31 days; peeling on feet; no discharge; had had discharge from the ears and the nose which had ceased ten days prior to leaving hospital. A brother was taken ill four days after the patient's return home.

CASE 7.—The patient, aged five years, was in hospital 28 days; peeling on feet; no discharge; tonsils enlarged and nodular condition of pharynx. The patient developed a purulent discharge from the nose two days after leaving hospital. A sister was notified as suffering from scarlet fever 15 days after the patient returned home.

These cases clearly point to the discharges as being the source of infection.

Table III. shows the number of cases treated in hospital and at home and the respective duration of treatment, with mortality.

TABLE III.

—	Number of cases.	Average duration of treatment.	Deaths.	Case mortality (per cent.).
Number discharged from hospital ...	325	34 days.	5	1·5
Cases treated at home	74	38 days.	3	4·1

Table III. is of value in showing that in patients treated at their homes the duration of treatment is much reduced from what it formerly was, the average duration for the hospital being 34 and in private 38 days. The mortality percentage is put down in this table not for the purpose of drawing any comparative conclusions. Such conclusions are undesirable and, moreover, are impossible, inasmuch as necessary factors are wanting. The low percentage mortality in the hospital, however, shows that treatment in centred hospitals is far from deserving a criticism so severe as to justify the statement that isolation hospitals should be abolished.

Such, then, are the main features of a year's work in our scarlet fever wards and I have taken the earliest opportunity of submitting them to you. I have dealt only with my own experiences, leaving out altogether the conclusions and methods of other workers. It is only by so doing and adding gradually to evidence already gathered that the vexed question of infection can be finally settled. I have put before you my contention that the respiratory tract is the source and centre of scarlatinal infection and I have put this contention before you not as a theory only but as a theory which has, I believe, stood the test of practice. If peeling *per se* were infectious then it is almost impossible to conceive how 204 patients discharged from the hospital in a peeling condition failed to be responsible for more than two "return" cases. This failure, moreover, of these patients to infect others was not due to any special condition of the homes and surroundings to which they returned. The conditions which did exist were just such as would put the method to a crucial test. For in nearly all the cases—as you will see by the statistics, each unit of which you must be acquainted with—the discharged patients were located in surroundings which were distinctly favourable to the spread of infection.

Although the primary object of an isolation hospital is the prevention of infection, yet the treatment of the patients is equally important, and I think our hospital records show that the short period of detention with the methods practised is not prejudicial to complete and early convalescence but rather the reverse. The patient is removed *sooner from the* infected zone and the risks of the many *complications are* minimised. Another advantage derived from this *system is* the increase of our hospital accommodation. *This is, of* course, a minor consideration, but from the point of view *of* a public official administering a large and expensive *department* it is a feature not to be disregarded. Can I not therefore claim that for the interests of public health, for the welfare of the patients, and for the advantage *of the ratepayers*, the system adopted has proved successful? It was not, I can assure you, without a feeling of *considerable* anxiety that I commenced to carry out a method so much at variance with the accepted traditions of the *profession*, but as case after case left the hospital without producing *any of* the dreaded results I felt to be *working on safe grounds*. Now, at the end of a year, I invite *your opinion* of the method employed.

Southampton.

ABSTRACT OF A CONTRIBUTION TO THE STUDY OF THE ACTION OF INDIAN COBRA POISON.[1]

BY R. H. ELLIOT, M.B., B.S. LOND., F.R.C.S. ENG., D.P.H. CANTAB.,
MAJOR, I.M.S.

THIS research[2] was undertaken by Major Elliot, who is on special duty making investigations into snake *venom* under the orders of the Secretary of *State for* India, with a view of accurately ascertaining the precise part played by the various important centres, nerves, and organs in the production of death from cobraism. After detailing the work of previous investigators and the methods *employed* in his researches Major Elliot came to the following summary of *conclusions* :—

1. Cobra venom acts directly on the muscular tissue *of* the blood-vessels or through their vaso-motor nerve endings, constricting the arterioles and thus raising the arterial *blood* pressure. It probably affects all organs alike. In the *frog* vessels the action can be traced down to dilutions of 1 in 10,000,000 In a cobra bitten man the concentration *of* venom *in* the *blood is* probably at least 30 times as great as this.

2. Cobra venom also acts directly on the *isolated frog* ventricle, killing it in a position of firm *systole if the solution* be *concentrated* and stimulating it if a *weaker strength* be *employed.* The limit of the speedy lethal action on the isolated heart is reached at a *concentration of about* 1 in 500 000. The stimulating action can be traced down to a *dilution of* 1 in 10,000 000. *This action* of cobra venom brings it into line with the glucosides of the *strophanthin* group Its action is more *rapid than that of strophanthin and is* certainly not inferior to it in *strength. Atropin sulphate* and cobra venom, when acting in the same solution, *intensify* each other's action and *produce more summation of effect* than one would have anticipated. This *detracts from the* value of the atropin salt *in the treatment of* cobraism and makes it a dangerous remedy. The blood pressure work has confirmed this view *of the case.*

3. Cobra venom powerfully affects the isolated mammalian heart when *solutions of* it are *perfused through the coronary* circulation. The *action* appears to be a *dual one—viz* : (1) a direct action on the muscular fibre, or on the *nerve endings,* closely resembling that which is produced on *the isolated frog* ventricle; and (2) an action on the intracardiac vagal mechanism, which makes *for* inhibition. The result is that in strong solutions we find an *irregular* and extreme excitation *of the* heart, *followed by early death in* a position of systolic tone. *If the concentration* be less *the early stage* of excitement yields to a prolonged *phase in* which the tonic action *of the* poison on the heart is most pronounced; the beat is regular, steady, and strong. Cobra *venom interferes* with the circulation through the heart in a marked manner. This is probably due (1) to a constriction of the *coronary vessels*, brought about by the direct action of the venom on the vessel walls, and (2) to the condition of tonus *into* [illegible] ss.

4. [illegible] low lethal doses cobra veno[illegible] [illegible]piratory centre. Such a *paralysis is* in these circumstances gradually evolved and in the *early* stages of the process there is often evidence of a phase of stimulation preceding the paretic phase. There is a gradually *increasing* venosity of the blood and in consequence thereof all the harmful results of slow asphyxiation are produced. If life is prolonged beyond the usual *term by* artificial respiration, and possibly also if the dose *of venom* is a very low lethal one which takes many hours to kill, the phrenic and other motor nerve ends may *become* paralysed, but *this* is certainly not an essential feature of death from lethal doses of cobra venom which kill within *five hours. I hope to make* a further communication on this subject later. The convulsions which precede death are purely asphyxial and can be at once stopped by artificial aeration of the blood. Each such convulsion is followed by a phase of exhaustion of the respiratory *mechanism* which is almost certainly central. If the dose of cobra venom administered be a large one, and especially if it be given intravenously, the respiratory centre is quickly and severely affected and respiration may cease almost at once. This cessation of breathing may be permanent if artificial respiration be not quickly started, but if the dose be a *smaller* one the rhythmic activity of the centre reasserts itself. At first there may be a number of deep spasmodic gasps and then the movements of respiration re-begin, very gently at the commencement and gaining force as time goes *on* till a normal rhythm is re-established or even a stage of stimulation is manifested Soon, however, the centre fails again and all the phenomena of asphyxiation appear. By applying cobra venom directly to the exposed medulla oblongata of the rabbit I have shown that the respiratory centre can be paralysed without the phrenic nerve ends or the heart being appreciably affected. If very large doses of venom are injected death may take place by cardiac failure before the respiratory mechanism has given way. We have here to do with the direct action of the venom on the heart muscle; the beats become rapid and shortened and the heart passes into a systolic phase in which it dies tightly contracted.

5 Cobra venom when given in low lethal doses subcutaneously raises the general blood pressure There *may* be a slight preliminary fall before the rise but often this is wanting. In the absence of further interference the blood pressure remains high till very near the end of life. In the asphyxial convulsions which herald death a further steep rise of blood pressure takes place; this is soon followed by a sudden and very rapid fall to death The high level of blood pressure is due to (1) the direct action of the circulating venom on the muscular tissue of the arterioles, causing a constriction of these vessels and thus opposing a barrier to the onward flow of the blood; (2) the increased force of the heart beat as the outcome of the direct stimulating action of the venom on its muscular tissue; and (3) the stimulation of the vaso-motor centre, as a result of the steadily increasing venosity of the blood. The slight preliminary fall of blood pressure which is sometimes seen is due to cardiac inhibition, but this subject will be reserved for discussion when dealing in the next section with the action of large doses of the poison. The late fall in the rate of the heart beat is due to cardiac inhibition; the latter is due to several factors. 1. A gradually progressive asphyxiation is taking place throughout such an experiment; this affects the vagal centre in common with the rest of the nervous system; the result is a stimulation of the inhibitory mechanism and a consequent slowing and weakening of the heart 2 The direct stimulating action of the venom on t[illegible] [illegible]s in the same direction as the [illegible] 3. There is distinct evidence [illegible] of the vagal centres is remov[illegible] continues to [illegible] the blood. 4 It is not [illegible] of the heart muscle follows the early stimulative action of

the venom. 5. Exhaustion of the heart is probably predisposed to by the strain put upon the organ in having to work for a long period against an abnormally high blood pressure.

We are now in a position to explain the sudden rapid fall of the curves of heart-beat rate and of blood pressure which ushers in death at the close of one of these long experiments. An over-strained and weakened heart is suddenly and violently called upon to bear a further burden, for respiration has ceased and the medullary centres are acutely asphyxiated. As a consequence there is a violent excitation of the cardio-inhibitory and vaso-motor mechanisms. The heart is slowed and at the same time has to work against a suddenly increased pressure and it gives way. In fact, we have the phenomena of asphyxiation in their entirety. The vessels of the splanchnic area are affected *pari passu* with those of the body generally and they in no wise act independently. The vaso-motor mechanism remains active throughout and is, as we have seen, profoundly affected by changes in the venosity of the blood.

6. Cobra venom, when injected in large doses and especially when given intravenously, causes: (1) a sudden fall of blood pressure; (2) a subsequent rise, provided that the dose has not been too large; and (3) a final fall to zero. The early fall is undoubtedly due to inhibition of the heart. It has been clearly shown that this is mainly brought about by the direct action of the poison on the vagal centres in the medulla oblongata, as it occurs before the accompanying failure of respiration has had time to act. Moreover, it is seen whilst artificial respiration is being actively carried on and can be checked in these circumstances by division of the vagi. On the other hand, there can be no doubt that asphyxiation of the vago inhibitory centre intensifies and maintains the inhibition which direct influence of the venom on the vagal centre produces. The spontaneous recovery of respiration or the application of artificial respiration has a powerful influence in mitigating the action of the venom on the vagal centre. In the same way artificial respiration, and to a less extent the spontaneous recovery of respiration, appear to act beneficially on the poisoned respiratory centre. Even if the heart is cut adrift from all central vagal impulses, whether direct or indirect, by the division of the vagi there yet remains evidence of a continued inhibition which must be attributed to the direct action of cobra venom on the terminals of the vago-inhibitory mechanism. This action would appear to be a direct one but there is every probability that it is indirect as well, in other words, that it acts through asphyxiation of the vagal terminals as well as by the poisoning of these parts by the circulating poison. There is, however, another factor which must not be lost sight of—viz., a direct exhaustion of the heart muscle as the result of irregular over-stimulation.

7. When the secondary rise of blood pressure which follows the primary fall takes place it is due to the same factors which determine its occurrence when small doses have been injected. It remains to explain why it is sometimes absent, brief, or ill marked. The explanation is simple: it is merely a question of cardiac failure. We have seen that the direct inhibitory action of the venom through the vagal centre is capable of overcoming the tendency which the blood circulating through the heart muscle has to throw that muscle into death in systolic tone. Were it not for these two rival forces to some extent equilibrating each other cobra poison would kill by its direct action on the heart muscle. When the doses are comparatively small, or when the vagi are cut or thrown out of gear by atropin, we find the tonic cardio-muscular influence of the venom in evidence, but when the dose of venom is large, and especially when it is given intravenously (the vagi remaining intact), the inhibitory action overpowers the muscular excitation and failure of the heart occurs. If the inhibition is sufficiently well marked no amount of arteriolar spasm that occurs will compensate it, consequently the blood pressure falls. When the dose of venom is a very large one the direct muscular stimulation may be so intense as to overcome the maximum inhibitory impulse and then the heart dies in systole with a quickened beat and is found after death as hard as a contracted post-partum uterus. In such circumstances any increase in the force of the heart is temporary, for the beat is probably a very partial one, the heart passes through a stage of excitement into one of increasing systolic tonus in which the contractions are very limited in extent.

THE TREATMENT OF INCONTINENCE OF FÆCES BY THE SUBMUCOUS INJECTION OF PARAFFIN.[1]

BY ARTHUR H. BURGESS, F.R.C.S. ENG., M.B., M SC. VICT.,

VISITING SURGEON TO THE MANCHESTER UNION HOSPITAL; SURGICAL OFFICER TO THE MANCHESTER CANCER PAVILION.

INCONTINENCE of fæces may arise from many and very varied causes but from the point of view of surgical treatment the cases may be broadly classed into two groups. 1. Those cases in which the sphincter ani still retains some amount of power but not sufficient to close entirely the anal orifice. It is conceivable that if by introducing paraffin into the submucous tissue on the inner surface of the sphincter we narrow the lumen of the bowel at this situation and thereby diminish the work which the sphincter has to perform, even a weakened sphincter may be able firmly to occlude the remaining lumen and so to render the patient continent. 2. Those cases in which the sphincter is completely paralysed, as in many nervous diseases, or has been entirely removed as after the operation of excision of the rectum. Various plastic procedures have from time to time been advocated with the object of surrounding the anus in such cases with muscular fibres diverted from their natural function, the chief muscles concerned being the gluteus maximus and the levator ani. Attempts have also been made to produce a valvular action of the rectal wall, such as by dissecting out the rectum, twisting it on its long axis, and refixing it, or by producing a sharp curvature or kink in its lower portion—attempts which are frequently unsuccessful. In two cases of incontinence of fæces belonging to this second group, one of which was associated with rectal prolapse, I have obtained great benefit from the submucous injection of paraffin into the lower portion of the rectum, as originally suggested by Gersuny of Vienna in 1899.

CASE 1.—The patient, a male, aged 58 years, was admitted to the Manchester Union Hospital with the history that three years previously he had undergone two operations elsewhere for fistula in ano, as the result of which the fistula was cured but he was completely incontinent of fæces. Two subsequent plastic operations were performed to relieve this condition, but were unsuccessful, and he had had absolutely no control over his stools for three years. On examination no trace of a sphincter could be discovered, the anus extended in a posterior direction almost to the coccyx and was surrounded by several dense scars, the result of former ulceration. Under anæsthesia I injected paraffin in several places into the submucous tissue of the rectum, commencing as high up as I could reach and working towards the anus. In all, upon two occasions, the rather large amount of 52 cubic centimetres of paraffin was introduced, its melting point being 111° F. This patient was shown at a clinical meeting of the Manchester Medical Society three weeks after the operation and I last heard of him nine weeks afterwards, during which interval he had had complete control over his motions and had never soiled his linen upon a single occasion.

CASE 2.—The patient, a boy, aged seven years, had been an inmate either of the Manchester Union Hospital or of the Swinton Schools attached thereto for the last five years, suffering from complete incontinence of fæces associated with a large rectal prolapse dating from infancy. During the past four years he had undergone linear cauterisation on two or three occasions, excision of the elliptical folds of the mucous membrane, and, finally, excision of the lower portion of the prolapsed rectum, all of which were unsuccessful in curing the prolapse, and had no effect upon the incontinence. The anus was abnormally large and lax and easily admitted four fingers, while there appeared to be an entire absence of sphincteric action. At first I injected only six cubic centimetres of paraffin submucously, but even this small amount certainly prevented the prolapse from descending with anything like its former frequency. On a subsequent occasion I introduced 27 cubic centimetres in three successive tiers, each tier consisting of three nodules of three cubic centimetres each and the prolapse has never since recurred, while the incontinence was very considerably improved. As, however, he still occasionally soiled his linen at night I decided to narrow the enlarged anus, which I did by a plastic procedure similar to Tait's flap-splitting operation for the repair of an incomplete laceration of the female perineum and this operation, performed 12 weeks ago, has resulted in complete relief. The boy is still under observation and his general condition has considerably improved since he acquired full control over his motions. An interesting point in this case was that when the patient was under the anæsthetic on the last occasion, before commencing the plastic operation I attempted to draw the former prolapse forcibly down but could not do so.

THE THERAPEUTICS OF THE ICHTHYOL COMPOUNDS: WITH SPECIAL REFERENCE TO ICHTHOFORM AND ICHTHARGAN.[1]

By JAMES BURNET, M.A., M.B., M.R.C.P. Edin.,
SENIOR CLINICAL TUTOR, EXTRAMURAL MEDICAL WARDS, ROYAL INFIRMARY, EDINBURGH; PHYSICIAN TO THE MARSHALL STREET DISPENSARY, EDINBURGH.

Exactly a year ago I had the honour and privilege of bringing before your notice my experiences with ichthyol in the treatment of pulmonary diseases.[2] When I was asked to give you something on the same lines this session I thought I could not do better than follow up my former paper by saying a few words about the various compounds of ichthyol. As some of you may know, I have devoted much time and careful research to the investigation of ichthyol and its preparations, so convinced am I that in it we possess a most valuable therapeutic agent the properties of which depend not so much on its containing a fairly large amount of sulphur in its composition as on its being a very powerful anti-inflammatory agent. This fact I have tried to bring to the notice of the profession in a short paper on the subject which I recently contributed to the *Journal of Tuberculosis.*[3] I may, perhaps, be allowed to quote the concluding sentences of that paper: "I am no believer in the theory that ichthyol owes its action to its antiseptic property nor in the view that its beneficial effects are entirely due to its action upon nutrition. We must go further afield and regard ichthyol in its true light as a vaso-constrictor and as an anti-inflammatory agent. This is its true action and the only one which is of much value in the application of the remedy to cases of pulmonary tuberculosis. Thus regarded ichthyol becomes a remedy of the greatest importance and one worthy the support of the profession everywhere." Ichthyol, I need hardly remind you, is a natural product that has been chemically treated. It is, in fact, a hydrocarbon oil obtained from a fossiliferous mineral, and this, after being acted on by sulphuric acid, gives us ichthyol-sulphonic acid. It is the ammonia salt of this acid which is known commercially as ichthyol. The history of the discovery of this hydrocarbon oil is of the greatest possible interest but it is somewhat outside the scope of the present paper.

Ichthyol, moreover, may be combined with quite a variety of active therapeutic substances. Thus we have iron-ichthyol, otherwise known as ferrichthol, calcium-ichthyol, sodium-ichthyol, and combinations with lithium, zinc, and mercury. Lastly, we have two quite recent ichthyol compounds—namely, ichthoform and ichthargan—the former being a compound of ichthyol with formic aldehyde and the latter the silver salt of ichthyol. Although I have had considerable experience with all of these time will not permit of my making more than a passing reference to most of them, reserving the greater part of my paper to a more detailed consideration of the two last named—ichthoform and ichthargan.

Iron-ichthyol or ferrichthol is a brownish-black, amorphous powder, very light and non-hygroscopic. It is practically odourless and tasteless and is best administered in cachet or in tablet form. The amount of iron contained in this preparation is about 3·5 per cent. Aufrecht of Berlin was one of the first to publish results of clinical tests with this compound. Personal clinical experience with ferrichthol shows that it is an excellent remedy in secondary anæmia. Thus in a case of subacute rheumatism in which the red corpuscles and the hæmoglobin were reduced they returned to normal within a month under the administration of 30 grains of ferrichthol per day. Another case in which this remedy proved valuable was that of a woman suffering from carcinoma ventriculi. She was able to take ten grains of ferrichthol in the 24 hours without producing nausea, although many other iron preparations previously given had not been retained. In a case of chronic renal disease where the patient suffered from intense headache and was markedly anæmic ferrichthol proved very useful not only in improving the condition of the blood but also in diminishing the frequency and severity of the cephalic pain. In severe cases of dysmenorrhœa associated with constipation and anæmia one of the most suitable remedies is ferrichthol in ten-grain doses thrice daily. In cases of chlorosis, on the other hand, I have seen no good results follow its persistent employment. It is, therefore, in secondary anæmia that it is of most value, and here no doubt the action of the iron is largely aided by the presence of the ichthyol with which it is combined. Although I have no personal experience of its use in skin affections it is interesting to note that Unna[4] advises its adoption in all chronic conditions, especially in urticaria and analogous skin diseases, in papular and bullous affections, and in lichen as it occurs in children. Again he finds it of service in diseases complicated either by chlorosis or by anæmia. Thus in eczemas occurring in anæmic subjects the ichthyol in combination with iron improves the circulation and so does good. No doubt iron-ichthyol has a wide sphere of therapeutic application in all diseased conditions associated with anæmia, and my own observations on its value in general diseases are fully borne out by Unna's with regard to dermatological conditions.

Sodium-ichthyol is a solid preparation and thus forms an excellent substitute for the internal administration of the ammonia salt as it can readily be made into pills. I am of opinion, however, that it is not nearly so active in pulmonary disease as is the original ammonia salt, though it is perhaps a little more readily taken by fastidious patients. In chronic gastric catarrh it has the power of checking the fermentative processes which form such a troublesome element in many of these cases. Generally speaking, where ichthyol is indicated this preparation should be prescribed, except in cases of pulmonary disease in which the original ammonia salt alone should be employed.

Calcium ichthyol is well suited for use in dermatological practice and I have found it readily taken by children. It is not, however, in my experience such a generally useful salt as are some of the others. The zinc salt finds many indications for its use in diseases of the skin and hence its value appeals most to dermatologists. It may be used as an ingredient in ointments and in certain cases is to be preferred to the ammoni. [illegible]
now speak as, not being [illegible]
have not felt it my du [illegible]
compound of ichthyol.

Within the last few years ichthyol has been made use of as a vehicle for certain insoluble agents such as cresol, eucalyptol, and even iodine. I have elsewhere[5] fully recorded my experience of the use of iodine anytol, as this new combination is called, and I need not stay to consider these quite recent additions to our pharmaceutical armamentarium. Of all preparations of ichthyol two stand out pre-eminently—namely, ichthoform and ichthargan. Of these I have been making trial for some time past and it is with the greatest possible pleasure that I take this opportunity of bringing the results of my work in this connexion before your notice.

Ichthoform is an amorphous, brownish-black powder, being practically odourless and tasteless. It is insoluble in ordinary media such as water, alcohol, and glycerine. When brought into contact with dilute alkalies it gradually splits up into its two components—ichthyol and formic aldehyde. The latter being a powerful germicide and the former an active anti-inflammatory agent, ichthoform is at once an antiseptic and an astringent. It is practically a non-toxic substance and can therefore be administered internally with comparative safety. Rabow and Galli-Valerio of Lausanne[6] made a thorough investigation into the properties of ichthoform for the purpose of clearing up the following questions:—1. What is its influence on the development of bacteria and fungi? 2. What is its value as a deodorant? 3. How is it borne by animals? 4. What effect has it on man? They found that gelatin plates infected with such organisms as bacterium coli, bacillus typhosus, bacillus icteroides, bacillus pyocyaneus, staphylococcus pyogenes aureus, and aspergillus niger when dusted over with ichthoform showed sterility during the first week, while vigorous development took place in control plates. In some cases development occurred during the second week, but the colonies were few in number with the exception of aspergillus niger. To show the deodorant action of ichthoform they took nine grammes of rabbit's fæces, diluted these with water, and then added half a gramme of ichthoform. This was then heated to a temperature of 37° C., but no disagreeable odour was felt even after the lapse of several days. They then took frogs weighing 32 grammes and introduced into the abdomen one-tenth of a gramme of ichthoform without producing any untoward result. They further experimented with guinea-pigs weighing 250 grammes and into these they injected half a gramme of ichthoform without producing any functional disturbance. As regards its effect on man it was found that from two to three grammes could be taken daily without harmful effects. It gave excellent results in intestinal diseases and also in the treatment of wounds, in the latter case forming a valuable substitute for other less agreeable substances such as iodoform.

[5] The Medical Times, Dec 20th, 1902.

Personally I have used ichthoform more or less extensively in four different directions: (1) as an intestinal astringent and antiseptic; (2) as a dusting powder; (3) as an ingredient in ointments; and (4) as a means of impregnating gauze.

1. *As an intestinal astringent and antiseptic* I have employed ichthoform in a large number of cases. In infantile diarrhœa, so prevalent in the summer months and no doubt due to the presence of micro-organisms, ichthoform has afforded me excellent results. My practice is to administer it to infants one year of age in doses of two grains every six hours in a little jelly. For children generally the dose ranges from two to ten grains given thrice daily. To them it may be given concealed in milk, cocoa, or gruel; but I much prefer to give it sandwiched between two thin pieces of buttered bread. In tuberculous lesions of the intestinal tract ichthoform has given me great satisfaction. Where diarrhœa is a prominent symptom I have ordered ichthoform in doses of from 10 to 15 grains thrice daily with marked effect. In a few instances the dose has been increased to 20, 25 and even to 30 grains, but these doses are somewhat excessive and may give rise to dryness of the throat and other troublesome phenomena These I have not observed personally in my own cases, but Schäfer of Munich mentions[7] especially dryness of the throat as resulting in one or two of his cases. I am of opinion that these undesirable symptoms were entirely due to the remedy being given in somewhat too large doses. As he states, however, ichthoform is non-poisonous and may be given in amounts even up to ten grammes a day without any harmful effects, and so too much importance need not be attached to the occurrence of these untoward results. In mild cases I have noticed great improvement even on the third day after its administration, and within a week, as a rule, the diarrhœa was found to have ceased. In more obstinate and severe cases not infrequently the dose of ichthoform has had to be raised to 30 grains before any evident effect was produced. In one or two cases I have tried rectal injections of mucilage of starch containing from 40 to 50 grains of ichthoform. As these were cases in which the patients were practically moribund no inference of any practical importance can be drawn as to the ultimate result of this form of treatment, but certainly in all cases the diarrhœa and abdominal discomfort were considerably alleviated. I would urge, however, that this means of employing ichthoform should be given a more extended trial.

Polacco of Milan has given us a short account[8] of his experiences with ichthoform in the treatment of enteric fever. He employed doses of half a gramme frequently repeated, so that in some cases the patients received as much as six grammes per day. This form of treatment was at times combined with ichthyol baths. 60 grammes of ichthyol were dissolved in a bath of hot water at a temperature of 95° F., and while the patient was in the bath this was reduced to 86° and even to 81·5°. The patient remained in the bath from 10 to 15 minutes and all the time an ice-bag was kept to the head. This combined method of treating enteric fever resulted in a reduction of the patient's temperature and a diminution in the frequency of the pulse, while the respirations became fuller and deeper. Polacco's statistics for the year 1900-01 give a mortality of 5·4 per cent. under this treatment, whereas previously it had been as high as 22 22 per cent.

2 I shall now pass on to consider my second use of ichthoform—viz., *as a dusting powder*. It is more particularly in cases of varicose ulcer that I have found benefit from this use of ichthoform. In many of these cases I have used it pure. Even foul discharging ulcers have healed under the simple daily free application of this powder. The fœtor rapidly disappears and the astringent action of the remedy soon makes itself felt. It thus stimulates healing by formation of healthy tissue. For foul ulcers I know no more trustworthy remedy. Admixed with equal parts of boric acid ichthoform will be found serviceable as a dusting powder for general use. Wherever there is a tendency to the formation of redundant granulation tissue during the process of wound-healing the area should be freely covered with ichthoform and zinc oxide in equal parts. For dysidrosis I find nothing so satisfactory as a powder composed of ichthoform, bismuth, and starch.

3. *As an ingredient in ointments* ichthoform is of special value. Time after time cases of chronic eczema have yielded to ointments into the composition of which ichthoform has entered. It may be used in strengths of from 1 to 5 per cent. with lanoline or vaseline as base. If used in too great strength it is apt to harden the skin and so delay the process of repair. Although, naturally, I have not had very great facilities for treating skin diseases with ichthoform still in the few that have come under my care I have made use of ichthoform with definite results. It is of service not only in subacute and chronic eczema, but also in the impetiginous eczema so frequently met with in school children, in certain affections of the nails, and also in scabies.

4 Lastly, I have suggested its use in the form of *ichthoform gauze*, to be used as a substitute for iodoform gauze for packing cavities. Thus for cavities left after removing tuberculous cervical glands or in cases of ischio-rectal abscess and fistula in ano nothing will be found so suitable and so efficacious as gauze thoroughly impregnated with ichthoform. I trust that a gauze of this nature will soon be made available for general use as a better and less expensive material than the present iodoform gauze.

If I were to sum up the conclusions which I have arrived at after considerable experience in the use of ichthoform in private and other practice I should say that: 1. It is one of the most efficacious antiseptics which we at present possess, more especially in cases of intestinal disease where its action is more certain and less harmful than salol and similar substances. 2. It forms an excellent substitute for iodoform in all cases where the latter is indicated. It is odourless and practically non-toxic, epithets which cannot be applied to iodoform. 3. For internal administration it is best given in small doses frequently repeated. Large single doses do not give the same satisfactory results and are more likely to produce untoward symptoms. As much as two drachms may be given in one day if divided into small, frequently repeated doses.

Although my experience with ichthargan is perhaps hardly so extensive as with ichthoform, still I hope to be able to place before you certain facts of practical interest and importance which I have noted during my employment of ichthargan. Ichthargan is a brownish-black, amorphous powder, containing 28·7 per cent. of silver, and is quite odourless and tasteless. It is readily soluble in warm or cold water, in dilute alcohol, and in glycerine. It is, however, insoluble in absolute alcohol, in ether, and in chloroform. Its solutions are clear when freshly prepared but become dark on exposure to light. It is relatively non-toxic.

---

[6] Therapeutische Monatshefte, April, 1900.

[7] Therapie der Gegenwart, October, 1900.

[8] Deutsche Medicinische Wochenschrift, 1901, No. 5.

Solutions should always be prepared fresh with sterilised water and filtered.

As regards the bacteriological properties of ichthargan Aufrecht has shown[9] that it is more powerful than silver nitrate in its action on the streptococcus, staphylococcus pyogenes aureus, on the bacilli of enteric fever and of diphtheria, and on gonococci. He compared its effects with those produced by collargol and protargol. He not only observed the superiority of ichthargan over these other silver compounds but he also noted that ichthargan possessed greater penetrating powers. Pieces of liver were placed in a 5 per cent. solution of ichthargan for 16 hours and it was found that the entire mass had been acted on, whereas pieces similarly treated with silver nitrate only showed a deposit of silver on their surface at the expiry of the test. It was further found that ichthargan was less poisonous than other silver salts. The lethal dose for guinea-pigs and rabbits was determined by experiment to be between 0·1 and 0·15 gramme per kilogramme of body weight, whereas that of [illegible] at of [illegible] ime. [illegible] ntra-venous injections in animals I pass over as I fear we may fall into error if we apply too dogmatically to the human organism the results obtained in the case of the lower creation. The great fact which we must constantly bear in mind regarding ichthargan is that more than two thirds of it is made up of ichthyol and hence it combines the therapeutic action of a silver salt with the valuable analgesic, antiseptic, and anti-inflammatory effects of the former. Moreover, it contains a very large proportion of silver and is exceedingly stable in solution and, above all, is comparatively non-irritating.

On the whole I think it will be more profitable for us to consider together the various clinical uses to which ichthargan may be put rather than to pursue further its pharmacological and bacteriological properties. The therapeutic uses of ichthargan may be classified under seven different categories and we shall now look at each of these very briefly.

1. *The employment of ichthargan in gonorrhœal urethritis.*—Much attention has been paid by continental clinicians to the use of ichthargan in this somewhat troublesome affection, notably by Lohnstein,[10] Furst,[11] Leistikow,[12] Duhot,[13] Goldberg,[14] Rudolf,[15] and others. My experience of its value in gonorrhœa has been chiefly amongst dispensary patients. These in some respects are a difficult class to deal with, as they not only lack the ordinary habits of personal cleanliness but they are apt to treat the condition somewhat lightly and to regard themselves as cured as soon as they are free from pain and genito-urinary discomfort. Again, many of them fail to return at regular intervals, while some make only one visit and nothing more is heard of them. Putting aside the cases where the visits were either too few or irregular to be of any clinical value I find there still remain 21 in which ichthargan was employed with more or less success. The mode of treatment adopted was to prescribe an alkaline diuretic mixture combined with a little tincture of hyoscyamus and to order morning and evening urethral injections of ichthargan in distilled water. The strength of solution employed varied from 1 in 5000 to 1 in 500, according as the case was acute or chronic in its nature. I found it always advisable to begin with comparatively weak solutions and gradually to increase the strength of the injection as I found the patient's urethral mucous membrane would tolerate it. In the majority of acute cases cure was effected within three weeks, the injection being employed, as a rule, thrice daily. In two subacute cases an injection of 1 in 1000 produced considerable irritation. Patients were always advised to continue the injection at bedtime for some days after they were considered cured. In chronic cases, perhaps more so than in any others, were ichthargan injections found very valuable. The strength used never exceeded 1 in 500 as this was found to be sufficiently energetic. Leistikow, however, mentions much stronger solutions, but these I have found from experience are apt to cause the patient considerable suffering. They may, indeed, have somewhat of a caustic action and so produce cicatricial contraction of the urethral canal, a most undesirable result. In the treatment of chronic urethritis I believe bougies containing a small amount of ichthargan (say, a quarter of a grain) would be more advantageous even than injections, as they are not only more readily applied to the diseased parts but they are also more penetrating in their effects. Still, even with simple injections I have had excellent results, only four out of my total of 21 cases having failed to be cured completely, although even these exceptional cases derived much benefit from ichthargan. Indeed, I fear their failure to respond to its action with the best results was entirely due to irregularity in habits, alcoholic and otherwise. It is only fair, however, to warn against the use of too strong injections, as although ichthargan is a comparatively innocuous remedy, still it has undoubtedly a caustic effect if used in greater strengths of solution than those already mentioned.

2. *Ichthargan in gynæcological affections.*—All of you know how valuable ichthyol is in gynæcological practice and its combination with silver in the form of ichthargan is equally beneficial. The cases in which I employed it were mostly those of leucorrhœa associated with a variety of conditions, such as pelvic cellulitis, endometritis, uterine retroflexion, and cervical catarrh. My method of application was by means of pessaries containing half or one grain of active ingredient made into a mass with oil of theobroma. One of these was placed in the posterior vaginal fornix every alternate night and this was followed by boric acid douches next day aided by saline aperients. Improvement was always manifested even after the first or second pessary had been inserted and treatment rarely required to be continued for more than a few weeks. The milder cases were cured within a week; the more severe cases necessitated assiduous application of the remedy for a month or six weeks. Instead of the pessaries a 10 per cent. solution of ichthargan in glycerine may be employed. Tampons of cotton-wool are soaked in this and placed in the vagina. I prefer, however, to use pessaries, as they are cleanlier and more effective in their results. The indication for the use of ichthargan in gynæcological practice is the necessity for an astringent plus an anti-inflammatory agent.

3. *Ichthargan in dermatological practice.*—In the treatment of skin diseases ichthargan will be found of service when employed in the form of ointments of varying strengths. Here again my dispensary experience has proved of great use. Cases of skin affection which otherwise I should not have had an opportunity of treating have time and again presented themselves and I need hardly say that I have lost no opportunity in experimenting with ichthargan wherever its employment seemed indicated. The ointments used varied in strength from 0·5 to 5 per cent. in equal parts of lanoline and vaseline. The stronger ointments are apt to cause much burning where the skin is at all tender or raw and for all ordinary cases a 1 or 2 per cent ointment is quite powerful enough. My cases numbered 39 in all, a small number of cases certainly but sufficiently varied in character to afford practical evidence as to the real value of ichthargan. They include two cases of tinea tonsurans, seven of seborrhœic eczema, three of herpes zoster, and six of various types of eczema, the remainder including ulcers, boils, and a variety of minor skin affections. Boils after being thoroughly treated by means of innunctions of a 10 per cent. ichthargan ointment are very frequently aborted. Ringworm affecting the scalp also requires the application of a 5 or even a 10 per cent ointment. Otherwise I think a 1 per cent. ointment is the most generally useful.

Unna[16] has recorded his experience of this remedy in cases of ulceration. He used it as a dusting powder in strengths of 1 and 5 per cent. diluted with talc. He combined this with zinc gelatin bandages and compresses and obtained good results. He states that ichthargan is a keratoplastic remedy, inducing the formation of new epithelium. His best results were obtained in old callous ulcers where the horny epithelium was first removed by the application of salicylic-creasote or salicylic-cannabis plaster mulls. He also observes that the antiseptic and keratoplastic properties of ichthargan suggest its use in cases of eczema, especially as it is met with on children's heads.

4. *Ichthargan in affections of the throat and nose.*—So far as I am aware the only literature on the use of ichthargan in

---

[9] [illegible]

[16] Monatshefte für Praktische Dermatologie, 1901, No. 2.

these diseases is a paper which appeared in the *Laryngoscope*[17] from the pen of Dr. B. Douglas of New York. I shall not attempt to do more here than to summarise his results, as my experience of ichthargan in this connexion is a very limited one. For nose and throat work a strength of 4 per cent. will be found most generally useful. In 10 per cent. solutions this remedy produces a disagreeable taste and nasal irritation which lasts from 15 minutes to two hours and causes some congestion of the mucous membrane, with profuse nasal discharge, lacrymation, and a certain amount of sneezing. After much careful experimenting with this new remedy Dr. Douglas found that the strength of solution generally most satisfactory was a 4 per cent. one. This usually caused slight burning and smarting but no congestion. If congestion was present at the time of application the surface soon became pale and contracted. Its action was prompt and lasted for from 15 to 20 minutes. In atrophic rhinitis it acts as a deodorant. It has also anti-inflammatory and stimulant effects and is a powerful modifier of nasal secretion. It is therefore *par excellence* the remedy for atrophic rhinitis. In hypertrophic cases the best results are got from a 4 or 5 per cent. solution. One of my own cases, that of a girl suffering from atrophic rhinitis, showed marked improvement after the use of a 1 per cent. ichthargan ointment. For syphilitic, tuberculous, and simple chronic laryngitis I have found pigments of a 5 per cent. ichthargan solution extremely useful.

5. *Ichthargan in diseases of the eye.*—Save of the value of a 0·5 per cent. ointment in cases of marginal blepharitis I cannot speak from personal experience of ichthargan as a remedy of importance in this connexion. Fortunately, however, for my present purpose I am able to quote from the experience of others better qualified to speak on this matter than myself. Thus Guttmann of Breslau has reported[18] its use in 61 cases of eye affections. These include 25 cases of acute catarrhal conjunctivitis, 13 of chronic conjunctivitis, seven resulting from affections of the lacrymal apparatus, ten of trachoma, six of ophthalmia neonatorum, and one of serpiginous ulcer of the cornea. His conclusions may be summarised as follows. In congestive catarrh it proves efficient although it cannot be said to replace the older remedies for such conditions. He recommends that further experiments should be made regarding its use in ophthalmia neonatorum. In affections of the lacrymal apparatus it is a very useful remover of purulent secretion. Its chief action, however, is developed in the dissecting forms of trachoma and it is one of the most useful remedies we at present possess for the medicinal treatment of pannus.

Marczel Falta,[19] writing of his use of ichthargan in cases of trachoma, says that he has used it in all forms and at all stages of this disease. He found that fresh cases were completely cured by ichthargan in from six to eight weeks. In chronic cases the pannus is reduced very speedily. He began with a 0·5 per cent. solution and gradually increased the strength to 3 per cent. These solutions are brushed over the affected part and by this means a pannus showed retrogressive metamorphosis ("Rückbildung") in from three to four days, and a case of recent trachoma could be cured in from six to eight weeks. Similar results were obtained by Gortaloff[20] in cases of trachoma, who therefore considers ichthargan an excellent remedy for the treatment of trachoma and its complications.

6. *Its internal employment.*—During the course of his investigations Aufrecht took five grains of ichthargan on three successive days and eight grains on the fourth. No loss of appetite was produced, the urine remained clear and free from albumin, while the stools were unaltered in appearance. This preparation may, therefore, safely be given internally. It may be given in solution in the proportion of from half a grain to two grains dissolved in eight ounces of water and of this a teaspoonful may be taken three or four times a day. It would seem useful in promoting the healing of gastric ulcers. It might also be given as an enema in cases of dysenteric and other intestinal lesions. Not having as yet tried ichthargan in the manner suggested I offer these remarks for what they are worth. Doubtless, further experience will convince us of their accuracy.

7. *Ichthargan in veterinary practice.*—This is, to me, a subject of much interest and I have gone through a vast collection of German literature in the hope of being able to place before you a review of the work that has been done abroad in this wide field. Time, however, forbids more than a passing reference. I wish particularly to mention the names of Eugen Bass, Eberhardt, and Leibert in this connexion. Eberhardt employed intravenous injections of ichthargan solution in cases of influenza in horses. The strength used for injection was 1 per cent. in distilled water. His results were such that frequently the temperature fell to normal within two days. This has suggested a similar use of ichthargan in cases of septicæmia as it occurs in man. I wish there was time to go more fully into this matter, as it is one of great interest, but I must not detain you longer.

From what I have said it will be evident that the various preparations of ichthyol have a wide sphere of therapeutic application. This remark applies especially perhaps to ichthoform and ichthargan which, after the parent remedy itself, are, in my opinion, two of the most valuable anti-inflammatory agents at present in our possession. They are certainly trustworthy in their action and therefore valuable additions to our therapeutic stock. They assuredly deserve to be used more extensively by the profession in this country and if these somewhat brief remarks lead to an awakened interest in the ichthyol compounds I shall feel more than rewarded for the trouble I have taken in bringing them before you.

Edinburgh.

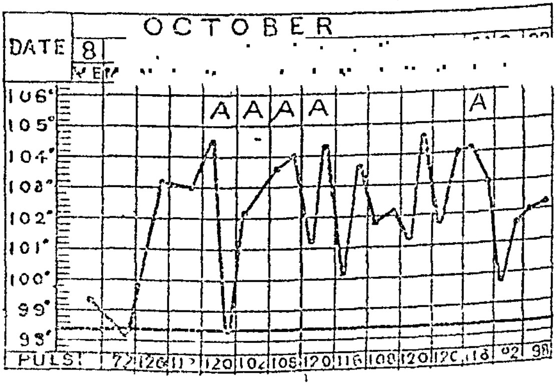
A CASE OF METRITIS AND CELLULITIS IN THE PUERPERIUM TREATED WITH ANTISTREPTOCOCCIC SERUM.

BY JOHN W. DUNCAN, M.B., CH.B. ABERD.

THE patient was a primipara, aged 24 years. The labour was normal after the case came under my care, except that the membranes were at the beginning bound to the uterus by slight adhesions that had to be broken before the os commenced to dilate. There was a history of irritation and discharge from the vulva before labour. The woman had been told by her mother and the nurse to bear down strongly and she had done so for a good while before the time when I first saw her, which was about 7 A.M. on Oct. 8th. Delivery took place the same day at 2 P.M. The perineum externally was intact but some abrasions were found in front afterwards. In the evening the fundus uteri was two fingers' breadth below the umbilicus and half a finger's breadth to the right side. The daily temperature and pulse-rate are shown on the accompanying chart. On the 9th the patient seemed to be doing very well; a fairly normal pulse tracing was taken. The fundus was one finger's breadth above the umbilicus and three fingers' breadth to the right. In the afternoon she complained of pain and the nurse gave her castor oil in the evening. On the 10th there was a motion of the bowels. Headache was complained of and there was pain in the lower part of the abdomen with marked tympanites. The fundus was half a finger's breadth above the umbilicus and one finger's breadth to the right. The tongue was brown and furred



A, Ten cubic centimetres of antistreptococcic serum injected.

on the dorsum, with whitish edges. The condition was diagnosed as metritis, and turpentine stupes were applied and aperient medicine was given. On the 11th the fundus was three fingers' breadth below the umbilicus and one finger's breadth to the right. Syringing with solution of mercuric chloride was used and iodoform pessaries were ordered; by mistake these were not got and a pellet of mercuric chloride was put in the vagina by the nurse, the consequence being that the patient was thrown into an agony of pain and could not pass urine. At a consultation which was held the consultant approved of the treatment which I was adopting. On the 12th the uterus was five fingers' breadth below the umbilicus. At 2 P.M., when the temperature was 104° F. and the pulse 120 per minute, ten cubic centimetres of antistreptococcic serum, obtained from Messrs. Burroughs, Wellcome, and Co., were injected, the vaginal outlet was dusted with iodoform, and an iodoform pessary was left in the vagina after the catheter was passed. At 8.45 P.M. the temperature was 98·4° and the pulse rate 88. The vaginal abrasions were perfectly clean, showing red granulations where a "diphtheritic" covering had been; the vulva was swollen and slightly everted from irritation by the mercuric chloride. On the 13th the temperature was 102·2° as shown in the chart. The pain and tympanites were both less but hardness and tenderness were now made out in the left inguinal region and also just above the pubes. The tongue was moist but was still red at the edges with a dirty grey coating on the dorsum. The vulva was now less red and swollen. A tear was discovered in the left side of the cervix and there were many smaller ones around the edge. Ten cubic centimetres of antistreptococcic serum were injected. On the 14th an injection of ten cubic centimetres of antistreptococcic serum in the back was given in the morning and was followed by a fall in the temperature and the pulse-rate. On the 15th an injection of ten cubic centimetres of antistreptococcic serum was given in the afternoon and was followed by a rise of temperature. There was some redness of the back at the site of the injections. The fundus uteri was five and a half fingers' breadth below the umbilicus. On the 16th, 17th, 18th, and 19th the pyrexia continued. No serum was used. On the 20th ten cubic centimetres of antistreptococcic serum were injected. On the 21st there was a decided improvement in the patient's condition. On the 22nd there were marked swelling and redness on both arms [illegible] on both legs—three [illegible] The improvement [illegible] continued and her temperature became subnormal on the 30th. On the 31st she was removed in an ambulance vehicle to a more suitable house. On Nov. 6th her temperature rose to 102·2° and the pulse-rate to 112. The calf of the right leg became red and swollen and an abscess formed in the leg. This abscess and the swelling in the right arm were opened but the swelling in the left arm disappeared without being incised. Convalescence was delayed for about ten weeks from the date of confinement. Some very slight œdema was left in the leg and foot and a slight limp was apparent. Five injections of antistreptococcic serum were given and a fall in the patient's temperature followed three of them—namely, those given on Oct. 12th, 14th, and 20th, while on the contrary a rise followed the two injections given on Oct. 13th and 15th. Only a few indeterminate cocci were found in the vaginal discharge. The onset of metritis was marked by a delay in the involution of the uterus, as shown by the measurements recorded above. The house where the patient was confined was a small fruit shop, the backyard of which abutted on the backyard of a rag-and-bone shop where green, mouldy rabbit skins were to be seen in the window. Next door to the fruit shop was a butcher's shop, and the patient's mother, who was present at the confinement, kept a fish and rabbit shop.

Hockley, Birmingham.

MEDICAL MAGISTRATE.—Mr. T. W. Heywood, M.R.C.S. Eng., L.R.C.P. Irel., D.P.H., has been appointed a magistrate for the borough of Darwen.

UNIVERSITY OF OXFORD.—Sir John Burdon Sanderson, who ceased to be a member of the Board of Faculty of Medicine on his resignation of the Regius professorship of medicine, has now been made a co-opted member of the board and has been re-elected chairman for the current year.

WESTMINSTER HOSPITAL.

FIVE CASES OF ULCERATIVE COLITIS.

(Under the care of Dr. W. MURRELL.)

CASE 1.—A man, aged 21 years, was admitted to Westminster Hospital on May 2nd, 1903, for diarrhœa and vomiting. He stated that for four months his bowels had been relaxed and that for six weeks they had acted very frequently, often 16 or 17 times a day. The motions were fluid and not infrequently mixed with blood. He had had treatment but without benefit. For two days he had suffered from persistent vomiting, with colicky pains in the abdomen, and it was the onset of this symptom which determined his visit to the hospital. His weight had fallen in two months from 9 stones 3 pounds to 6 stones 12 pounds. He was resident in London and had never been abroad; he had had no previous illness and his family history was unimportant. On admission he was found to be thin and wasted and his eyes were sunken and surrounded by dark rims. He looked anæmic but his red blood corpuscles numbered 4,650,000 and the leucocytes 15,400 per cubic millimetre. His mental condition was not impaired and he was always bright and cheerful. His temperature was elevated and for many months ranged from 100° to 103° F. daily. The pulse was 108 and of poor quality. Widal's reaction was not given. The vomiting speedily subsided and was never a troublesome feature, but the diarrhœa persisted, there being usually about 60 motions a week, most of them liquid and offensive. They were passed with very little pain and consisted chiefly of mucus, with from time to time a little blood. The deposit contained strands of mucus in which were many leucocytes but no circular pits denoting the openings of mucous glands. The bacteria of the fæces were almost entirely streptococci but sometimes they were present only in scanty numbers, other organisms being seen of which the majority were large bacilli. The tongue was clean, red, and slightly irritable. The appetite from first to last was good and the patient constantly expressed a desire for more food. Thirst was not a prominent symptom. The urine was of specific gravity 1022, faintly acid, and contained neither sugar nor albumin. The abdomen was not distended and contained no free fluid, there was no enlargement of the liver or spleen, and there was only slight tenderness over the descending colon.

As the patient was in the hospital for eight months it would serve no useful purpose to trace his progress from day to day. The elevation of temperature was constant and the diarrhœa continued persistently and never alternated with periods of constipation. In June an ischio-rectal abscess was detected on the left side and in August there was a similar formation on the opposite side. He was kept strictly in bed and for many months occupied a bright and airy room at the top of the hospital. The windows on account of the fœtid odour were kept constantly open, so that the patient had practically open-air treatment. His diet consisted chiefly of milk with a little beef-tea and plasmon arrowroot. Light puddings, chicken panada, and other easily digestible foods were tried from time to time but invariably increased the frequency of the motions. The medicinal treatment consisted in opium and morphine in all forms, including enemata, carbonate of bismuth in doses varying from a drachm to half an ounce every four hours, acetate of lead, perchloride of iron, and other astringents, antiseptics such as β naphthol, salol, perchloride of mercury, and various preparations of formic aldehyde, powdered ipecacuanha given dry and with the usual precautions, and many other drugs, none of which seemed to exert the slightest beneficial effect. The patient's general condition was so unsatisfactory that it was considered inadvisable to resort to rectal injections of nitrate of silver. The question of operation was frequently discussed and was negatived. Early in January, 1904, the range of temperature was lower and was often subnormal, the diarrhœa was more persistent, and the patient passed 191 motions in one week with 53 in the four following days. As he was rapidly losing ground it was decided to give him the chance of an operation.

On Jan. 15th, under A.C.E. mixture, Mr. W. G. Spencer made an incision in the right iliac fossa and exposed the appendix which was found to be bound down by adhesions, so that it was impossible to catheterise it as had been intended. A small incision was consequently made in the cæcum close to the origin of the appendix and a rubber catheter was inserted. An attempt was made to sew in the tube but this was impracticable owing to the rottenness of the gut wall. A knuckle of intestine was therefore withdrawn from the abdomen and fastened by a colotomy rod passed through the mesentery. Four pints of normal saline solution at 100° were poured down the catheter and ran out by the rectum. There was found to be a small perineal fistula. The exposed knuckle of gut was powdered with iodoform and covered with several layers of gauze. At 7 P.M. on the day of the operation the temperature fell to 96°, but after a hypodermic injection of morphine rose at 11 P.M. to 99°. On the following day the wound was dressed and the patient vomited five times. The temperature remained low, falling to 96° in the evening. On the 17th the vomiting continued and the temperature ranged from 97·4° to 95°, the pulse being 100 and the respirations 20. On the 18th the temperature was but little over 95° at any time during the day and the patient died early on the morning of the 19th after an illness of about 12 months' duration.

Necropsy.—At the post-mortem examination (which was performed by Dr. R. G. Hebb) all the tissues were found to be extremely pallid and exsanguine. In the peritoneal sac was much slimy pus and the serous membrane was pallid, smooth, and slimy. The whole of the large intestine from the valve to the anus was in a condition of chronic ulcerative colitis, the mucosa was thickened and œdematous, villoid in places, of blackish hue in parts, and in parts purplish. The mucosa was cut up into islets of varying size by deep fissures which reached in places to the muscular coat. The colon was contracted throughout. In the last nine inches of ileum were a few deep-set small ulcers. The mesenteric glands were much enlarged and some were cretaceous. The appendix was buried in a mass of fibrous tissue, the fibrosis extending to the rectum and adjacent parts. All the other organs of the body were normal.

CASE 2 —A man, aged 25 years, was admitted into Westminster Hospital on July 10th, 1903, with a history of diarrhœa of three months' duration. He had been for a short time in Charing Cross Hospital where he had been treated with a mixture of salicylate of bismuth, tincture of opium, and hydrocyanic acid. He was a Londoner and had never been out of England. He stated that he had had rheumatic fever nine years previously when there was diarrhœa with blood and mucus in the motions. On admission and for some weeks subsequently the temperature was slightly elevated but rarely rose above 100° F. There was persistent diarrhœa, there being usually about 70 motions a week, for the most part watery, offensive, and containing blood and mucus. On microscopical examination they were found to contain torulæ, streptococci in two varieties, bacilli (the bacillus coli communis and others), epithelial cells (columnar and spheroidal), and much pus with the débris of food. No shreds of mucosa were seen. Later the organisms of the fæces were almost exclusively bacilli, cultivation yielding not only the bacillus coli communis but a large bacillus not staining by Gram's method and probably the bacillus proteus vulgaris. No recognisable pathogenic organisms were detected. Vomiting was a prominent symptom, the contents of the stomach being evacuated from three to five times in the 24 hours. The liver was not enlarged and there was no tenderness over the abdomen. The urine was free from albumin and sugar. The treatment was in the main that followed in the previous case, but for a time the patient was given two drachms of sulphate of magnesium dissolved in the minimum of water at 6, 7, 8, and 9 o'clock in the morning and at 3, 4, 5, and 6 o'clock in the evening with five grains of quinine at the first and last dose. It was not clear, however, that it did any good. In August a bed-sore formed over the left trochanter and another over the crest of the ilium. The diarrhœa continued with unabated severity, but the temperature was lower, being at times subnormal. His general condition was most unsatisfactory and on August 31st he was practically pulseless. It was thought to be useless to restrict his dietary and he was given solid food. From that day he gained strength, the temperature returned to the normal, and the diarrhœa ceased. On Oct. 22nd he was sent to a convalescent home, but on Nov. 13th was brought back in an ambulance with a return of the fever and diarrhœa, there being 59 motions in the first week and 97 in the next. Little by little, however, the acute symptoms subsided, the appetite returned, he gained weight, and was discharged apparently well on Jan. 17th, 1904, after an illness of ten months' duration.

CASE 3.—A woman, aged 37 years, was admitted into Westminster Hospital on July 21st, 1903, having been brought from Lambeth in an ambulance. She stated that she had been taken ill ten days previously when she was "burning hot" and had severe pains in her legs. She had been in bed for five days suffering from diarrhœa, for which she had had medicine and slop diet. There was no family history of importance and her only illnesses were pleurisy nine years previously and a more recent attack of influenza. Her temperature soon after admission was 105° F. and for three days she was repeatedly sponged. Her temperature during the time she was under observation ranged from 105° to 102°. Widal's reaction was not obtained. There was no headache, nausea, or epistaxis, and for a time no vomiting. The tongue was covered with a dirty brown fur and the appetite was bad. There was persistent diarrhœa, the bowels being opened from seven to ten times a day. In six consecutive weeks the motions numbered 51, 69, 58, 73, 80, and 104. The stools were fluid and contained but little fæcal matter. There was a little blood, not in clots, and there was a considerable quantity of mucus stained green. The passage of the motions was preceded by pain. At a later period they were dark in colour and often offensive. She vomited from time to time, but not every day. The diet consisted of milk, a little beef-tea, and plasmon. The medicinal treatment consisted of tincture of iodine and carbolic acid by the mouth and enemata of opium. She gradually sank and died from asthenia on the fiftieth day of the illness.

Necropsy.—At the post-mortem examination (which was performed by Dr. Hebb) the body was much emaciated; the surface and viscera were pallid and exsanguine. There was slight diffuse pigmentation of the thighs. The stomach was normal. There was arterial injection of the small intestine. The mucosa was normal. The large intestine was dilated and in a condition of ulcerative colitis throughout. The remaining mucosa was much thickened and standing up above the ulcerated gut from two- to three-eighths of an inch. Where the mucosa was absent the wall was quite thin, especially about the ascending colon and sigmoid flexure, the coil of the latter being firmly adherent by central union. The mesenteric glands were slightly enlarged. The other organs were normal.

CASE 4 —A man, aged 31 years, was admitted into Westminster Hospital on July 11th, 1903, suffering from diarrhœa of three months' duration. The temperature was but slightly elevated and never rose above 100° F. The motions averaged about four a day. There were no mucous shreds or other adventitious substances in the fæces. They contained the bacillus subtilis, the bacillus coli communis, and a large spore-bearing, non liquefying bacillus. Cultivation yielded bacilli and micrococci, but no streptococci were present. The tongue was moist and clean and the appetite was good. There was no tenderness over the liver or the colon. The patient had never been abroad and had had no previous illness with the exception of an attack of bronchitis. Two brothers and one sister had died from phthisis. The patient was carefully examined but no lung mischief could be detected; there was no sugar or albumin in the urine and he was not markedly anæmic. He rapidly lost flesh and three weeks after admission suffered from persistent vomiting. He was put on milk diet and was given first salol and then cocaine with enemata of opium. He died on August 22nd, after an illness of about four months' duration. No necropsy was obtained.

CASE 5.—A woman, aged 30 years, was admitted into Westminster Hospital on April 20th, 1903, with diarrhœa of three weeks' duration, during which she had been confined to bed and had received medical attention. There was no family history of importance and her only previous illnesses were anæmia and occasional attacks of summer diarrhœa. She had never been out of England. On admission the temperature was 103° F. and it ranged from 100° to 102°

during the time she was in the hospital. Widal's reaction was not obtained. The pulse was 120, quick, and of low tension. The bowels were opened on an average six times a day. The motions were liquid and offensive and contained fæcal matter with a good deal of blood and but little mucus. [illegible] more than twice a day and [illegible] every day, [illegible] matter being green in colour. The patient was very weak and looked pale and wasted. There was no pain and she complained of nothing but the diarrhœa and general weakness. The tongue was pale, moist, and slightly furred. The appetite was good and she frequently asked for solid food. There was no abdominal distension and no tenderness could be detected. The liver and spleen were not palpable. A soft apical systolic murmur was heard but it was not conducted into the axilla. The treatment consisted of hypodermic injections of morphine with enemata of opium. The patient gradually sank, the temperature fell to 96°, and she died on May 7th after an illness of about five weeks' duration. No necropsy was obtained.

Remarks by Dr. MURRELL.—It is probable that all five of these cases are examples of ulcerative colitis, although in only two of them was the diagnosis confirmed by necropsy. The general course of the symptoms and the high rate of mortality confirm this view. Ulcerative colitis is by no means a common disease, at all events in London. I have consulted the records of the hospital and find that in 19 years, from 1884 to 1902 inclusive, there were only 15 cases, 11 in men and four in women, and of these there died five men and two women. In one of these cases, that of a man, aged 26 years, there were abscesses of the liver which after perforating the diaphragm opened into the lung and were partially evacuated through the bronchi. It is probable from the report of the necropsy that this was in reality a case of colitis dysenterica and should not be included in the list. That would give 14 cases of ulcerative colitis in 19 years with a mortality of 40 per cent. in the men and 50 per cent. in the women Including the present five cases we get a mortality of 46 per cent. in the men and 66 per cent. in the women.

The term "ulcerative colitis" or "simple ulcerative colitis" is admittedly a bad one, sanctioned only by long use, for ulceration of the large intestine may be dysenteric, tuberculous, or malignant in origin and is not uncommon in enteric fever. Considerable difficulty exists in distinguishing between different forms of inflammatory disease affecting the colon and post mortem it is impossible from an inspection of the large intestine alone to discriminate between ulcerative colitis and chronic dysentery. The clinical features of the disease, however, are sufficiently characteristic. Respecting its origin and causation little is known. It attacks both sexes but appears to be commoner in men than in women, for of 28 cases recorded at Guy's Hospital 15 were in men and 13 in women, whilst of the 19 cases at the Westminster Hospital 13 were in men and six in women, giving a total in 47 cases of 28 men and 19 women. The majority of cases occur between the ages of 20 and 30 years, but one of our cases was a boy aged 13 years. The onset is insidious, there is no rigor, and nothing in the early stage to distinguish it from an ordinary attack of diarrhœa. Pain is not a prominent symptom and as a rule there are no tormina nor is there tenesmus. No cause is as a rule assigned by the patient, although in one instance it is said to have followed an attack of enteric fever. One of our patients was in the habit of eating large quantities of a sweetmeat known as milk chocolate and the possibility of the disease having commenced as a tyrotoxicon infection was considered but there was nothing to support that view. The temperature was in most cases persistently high, whilst in others it was little above the normal. As a rule it was subnormal during the last 48 hours of life. In some cases vomiting was persistent, whilst in others it was absent or of rare occurrence. In all cases the patient rapidly lost weight and displayed signs of great weakness. There was little or no mental depression and most of the patients were cheerful to the end. There was no loss of appetite and a constant desire was expressed for more food and often for some particular article of diet. The diarrhœa was always the prominent feature and in most cases it was practically unceasing. The microscopical examination of the fæces gave no uniform result. In one instance the motions consisted of an almost pure culture of streptococci and it was thought that injections of anti-streptococcic serum might be indicated, but on the following day without any apparent reason the streptococci disappeared and were replaced by a totally different organism. It has been suggested that the ulceration of the colon may be due to an amœba but there is nothing definitely to support this view. Metastatic abscesses are rare and little or no change is found in the liver. It is said that the disease is associated in some way with kidney trouble but this is the exception and not the rule.

The post-mortem appearances present considerable uniformity and in both our cases there was a condition of ulcerative colitis throughout. In Dr. W. H. Allchin's classical case recorded in vol. xxvi. of the Transactions of the Pathological Society of London—the specimen is in the museum of the Westminster Hospital—there were in the ascending and transverse colons numerous circular punched-out ulcers varying in size from that of a threepenny-piece to that of a florin. In another case at the hospital, that of a woman, aged 50 years, the mucosa of the colon from the splenic flexure to the anus was extensively ulcerated, the remaining ragged mucosal areas being much thickened. The vermiform appendix is not infrequently involved and in one case it was glued to the pelvic brim by soft adhesions. It contained a fæcal calculoid of about the size of a grape-stone and from a minute aperture at the apex there was exudation of pus.

The duration of the disease is variable and in some cases it may extend over a period of three or four years. The treatment is essentially unsatisfactory; in our cases almost every drug or combination of drugs likely to be of use was tried, with the exception of injections of nitrate of silver, and they all failed. Whether surgical interference is likely to be more successful it is difficult to say. The operation commonly proposed is that of establishing an anastomosis between the ileum and the lower end of the colon, and failing this a right-sided colotomy. The operation performed by Mr. Spencer promises well, although in this particular case from unforeseen difficulties it was not successful. Continuous irrigation of the bowel either with plain water or boric acid solution is probably the key to the situation.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A CASE OF SPONTANEOUS PERFORATION OF THE INTRA-PERICARDIAL PORTION OF THE INFERIOR VENA CAVA.

(Under the care of Mr. I. McW. BOURKE, late house physician.)

THE patient, a man, aged 60 years, was taken into the Royal Southern Hospital at 2 A.M. on a police ambulance. He had been seen to fall suddenly while walking along the street. Mr. Bourke saw him immediately after admission. He was lying on the ambulance talking very volubly but would tell nothing about himself except that he had been drinking. On examination there were no signs of injury. The pulse and respirations were quite quiet and the tension of the former was good. The patient expressed a desire to micturate and there being nothing in his condition to cause alarm he was allowed to do so. As the man lived close by Mr. Bourke arranged with the police to take him home. He was called five minutes later just as the patient was leaving and found him completely collapsed; he died in five minutes.

Necropsy.—At the post-mortem examination rigor mortis and post-mortem hypostasis were marked. There was some cyanosis of the head and the neck. In the right and left pleuræ there were old adhesions, these being scattered irregularly in the left. No fluid was present. Old scars were present in both apices of the lungs which were a little emphysematous. The left ventricle of the heart was hypertrophied and dilated. The pericardium was full of blood and two large masses of blood clot were causing considerable [illegible]. At the anterior part of the [illegible] the heart there was present [illegible] adventitia and part of the [illegible]bling a form of ulcer. The margins were not indurated nor was the surface of the patch ulcerated or sloughy; simply the tunica intima lay exposed, the patch being surrounded by no definite margin and the three layers gradually merging one into the other. In the centre of the patch there was a small perforation into the inferior vena cava which was the cause of death. Two similar patches were present, one on the lower branch of the left pulmonary vein and the other on the posterior part of the pulmonary artery. The pericardium, apart from these erosion-like ulcers, was healthy. There was marked atheroma in the aorta, many patches being calcified. The liver was fatty with a thickened capsule. There were no adhesions. Its substance was soft and friable. The pulp of the spleen was somewhat fibroid; its capsule was thickened. There were signs of old perisplenitis. Nothing abnormal was found in the alimentary system. There were signs of early cirrhosis in the kidneys. The bladder, ureters, and suprarenals were normal.

Remarks by Mr. BOURKE.—If the perforation had occurred a few minutes later the patient would have died in the street. This would have been an unfortunate occurrence which I do not think one could have foreseen. I venture to publish this case as I have never come across a similar one neither can I find any record of such a case. I am indebted to Dr. J. Lyn Dimond, pathologist to the hospital, for the post-mortem notes of the case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Cardiac Dulness in Cases of Cancer.—A Case of Properitoneal Hernia.

A MEETING of this society was held on March 8th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. W. GORDON (Exeter) read a paper on the Cardiac Dulness in Cases of Cancer. He said that some years ago he had noticed in cases of gastric cancer, in which ordinary emphysema could not be thought to exist, that the cardiac dulness was greatly reduced or obliterated in the recumbent posture. After observing this in many instances he had rightly diagnosed cancer on the strength of it in five consecutive cases. Since then it had been noticed in many cases. (The normal cardiac dulness in the recumbent posture was not the same as in the erect posture. The absence or reduction of the dulness in cases of cancer was looked for in the recumbent posture only.) The following was a summary of results. Reduction or loss of cardiac dulness was common in cases of cancer, especially in cases of abdominal cancer towards their end. It was not, however, always present. It might precede cachexia, marked wasting, and loss of skin elasticity, but seemed absent in the earliest stages. If absent at first it might slowly develop towards the end It might be found, but apparently rarely, in other diseases and it did not seem to occur in cases of sarcoma. When present in a doubtful case its presence was very suggestive of the existence of a cancer. When absent in a doubtful case of considerable duration it was slightly suggestive that the case was not one of cancer. In assessing the value of this physical sign it was of course necessary to exclude the existence of all ordinary causes of alteration of the area of cardiac dulness. The explanation appeared to be that the margins of the lungs extended across the front of the heart (this was found post mortem to be the fact) owing to a loss of elasticity in their substance similar to the loss of elasticity often observed in the abdominal skin in many cases of abdominal cancer.—The PRESIDENT said that Dr. Gordon had in his cases been most careful to exclude the diminution of the cardiac dulness such as might be due to emphysema of the lung, retraction of the heart, or to atrophy of the heart itself. The explanation given was that absence of cardiac dulness was due to a change in the lung tissue. He asked if any microscopical examination had been made of the atrophic lung tissue and if any change had been found. He suggested the importance of examining a large series of cases of cancer in order to find out in what proportion of cases this sign was present.—Dr. H. S FRENCH asked whether Dr. Gordon laid stress on the absence of cardiac dulness when the case was first seen or only when the cardiac dulness disappeared under observation —Dr. GORDON replied that he had examined the lung of one case microscopically but had been unable to demonstrate any change. He was of opinion that the loss of elasticity was a condition which could not be demonstrated by microscopical examination. Both the initial absence of the cardiac dulness and its disappearance under observation were important.

Mr. H. BETHAM ROBINSON read an account of a case of Properitoneal Hernia. He said that the patient, who had been the subject of left inguinal hernia for some years, was admitted into St. Thomas's Hospital with symptoms of obstruction of three days' duration. There had never been any difficulty in reducing the hernia and on admission there was no evidence of a hernia. Abdominal section was performed and a loop of small gut and matted omentum were found entering through a small opening into a pouch situated behind the left side of the lower part of the abdominal wall at the side of the bladder. On dividing this ring the congested and matted omentum could be withdrawn but not so the bowel which was firmly adherent to the sac. On opening up the inguinal canal the bowel presented at the normal site of the inner ring. The bowel here was quite black and lacerated easily on attempted separation. It was evident that the gut occupied, and was strangulated in, a pouch behind the abdominal wall and that it was gangrenous. Having packed round the inner opening with gauze the gut was separated from the sac, withdrawn through the inner opening, and brought out externally. Four and a half inches of gut were resected and an end-to-end junction was made. The patient died somewhat suddenly four hours after the operation. A careful necropsy showed that there was a bilocular sac; an inguinal pouch extended through the canal to the external ring imbedded in the elements of the cord; the testis was normally placed. This inguinal sac communicated by a small opening with another sac deeply placed behind the abdominal wall in the subperitoneal tissue; this inner sac was of an oval form and reached from the side of the bladder outwards into the iliac fossa. Its small inner opening in which the gut had been strangulated was the true internal ring. The case was thus a typical example of a properitoneal hernia, as described by Kronlein and Breiter. It differed, however, from the majority described by them in that the testis had properly descended but from the relation of the sac to the elements of the cord there was little doubt that the sac was a patent funicular process which had undergone dilatation in such a manner as to assume the bilocular form.—Mr. W. MCADAM ECCLES said that it was necessary to distinguish between the properitoneal and the interstitial form of inguinal hernia. He mentioned the great preponderance of the properitoneal variety in the male subject and said that it was his belief that this form only occurred in males. The interstitial variety, however, was proportionately more common in females. Probably in most if not all cases of properitoneal hernia there was some congenital defect in the descent of the testis and he asked if the testes on the two sides in Mr. Robinson's case were of the same size. The production of the interstitial hernia was often due to the blockage of a small external abdominal ring by a testis; the descent of viscera into the accompanying processus vaginalis caused dilatation of the peritoneal pouch in an upward and outward direction in a plane of the abdominal wall in front of the transversalis fascia. In many cases of interstitial hernia there was no prolongation of the sac into the scrotum. He suggested the importance of exploration in all cases of imperfectly descended testis accompanied by a definite hernia.—Mr. ROBINSON, in reply, said that a crural form of properitoneal hernia did occur in females. In his case the testes were normal.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Electric Currents of High Frequency.—Chronic Intestinal Obstruction.

A MEETING of this society was held on March 2nd, Professor JOHN CHIENE, the President, being in the chair.

Mr. H. J. STILES showed an infant after Ligature of Both Common Carotid Arteries for Chronic Hydrocephalus. The vessels were ligatured at an interval of two weeks in order to cut off the blood-supply to the plexuses and no mental disturbance ensued from the great limitation of the supply. The operation was completed nine weeks previously and the head had only undergone an enlargement of a quarter of an inch.

Dr. D. CHALMERS WATSON showed a woman suffering from

Exophthalmic Goitre of ten years' duration, and her son, aged ten years, who also showed symptoms due to alterations in the Thyroid and in the Parathyroid Secretion.

Dr. BYROM BRAMWELL showed a boy, the subject of Pancreatic Infantilism, who had shown great improvement under treatment by pancreatic extract. Dr. Bramwell said that this was a new disease and he had not seen any previous description of the affection. He had shown the same boy to the society two years ago as an example of infantilism and he had then expressed the opinion that the condition was due to defective pancreatic secretion. At that time the boy was 4 feet 4⅛ inches in height and weighed 4 stones 7 pounds. He looked like a boy of the age of 11 years, but was really then 19 years old. For nine years previously his growth and development had been arrested and he had suffered constantly from chronic diarrhœa, there being from five to six motions daily. The boy was perfectly well formed and presented no evidences of sporadic cretinism. The diagnosis which Dr. Bramwell then made was that the diarrhœa was due to defective metabolism caused by defective pancreatic secretion. This was shown by (1) the stools containing an excess of fat and on administering pancreatic extract this fat underwent a great diminution; (2) his urine on a milk diet contained a very small amount of phosphoric acid, but this increased greatly on giving him pancreatic extract; and (3) capsules containing iodoform and made of a covering insoluble in the gastric but soluble in the pancreatic secretion were given. On testing his saliva one hour after swallowing these there was no evidence of iodine or iodates; while after giving these along with pancreatic extract the reaction readily showed itself. Under treatment by pancreatic extract the lad had grown five inches and weighed 8 stones 8 pounds. He now looked much older in the face and the sexual organs had undergone a development, the pubic hair and descended testicles being now present. Dr. Bramwell thought that this new disease was curable through the administration of pancreatic extract.

Dr. JOHN THOMSON showed two cases of Infantilism (males, aged 18 and 24½ years respectively) attended with severe dyspepsia and diarrhœa of many years' duration and probably connected with some morbid condition of the pancreas.

Dr. ALEXANDER BRUCE (at the request of the council) gave a demonstration of Electrical Currents of High Frequency, with their mode of production and therapeutic applications. He said that for several reasons electrical treatment had been received by the medical profession with indifference and even contempt. The result had been, however, the discovery by the laity that there was something in such electrical treatment and consequently all kinds of companies had been started to carry on this treatment and most of these were run on commercial and unscientific lines. High-frequency currents were periodically alternating currents and the frequency of this alternation was exceedingly high. Such currents stimulated both nerve and muscle and the degree of stimulation bore a definite relation to the frequency of the alternation. The slower the alternation (within certain limits) the greater the stimulation—as, for example, from 2000 to 3000 per second. With currents of from 5000 to 10,000 per second there was a gradual diminution in the effect produced and with alternating currents above 10,000 per second hardly any stimulation was produced. No mechanical means that had been devised enabled them to obtain currents of a greater frequency than 10,000 per second. The spark, however, from a Leyden jar consisted really in a series of discharges varying from 900 to 30,000 million per second and such were named high-frequency currents. If a series of sparks were passed from the two poles of such a jar while each lasted only the fraction of a second a succession of rapidly dying down discharges was obtained. If it were so arranged that before each died down another took its place a fairly continuous periodic alternating current of enormous frequency was obtained. Such a current could not be directly utilised from the poles of the Leyden jar, but whenever such a discharge took place from the poles a similar discharge occurred from the outside of the jar and in all apparatus it was this discharge which was employed. Instead of employing Leyden jars, which readily broke, condensers were used. These consisted of sheets of tinfoil between plates of glass. The strength of these could be easily increased or lessened by varying the size of the tinfoil. To prevent short-circuiting the condenser was placed in a glass vessel filled with petroleum. One of the simplest means of charging the condenser was the static machine, as it was most convenient and broke down least easily; it was also inexpensive to work. The uncertainty of its working in damp weather was avoided by using one made of vulcanite plates. Current could also be obtained from the main. Another method of charging the condenser was the employment of an induction coil. It gave a very satisfactory result when worked by accumulators; the spark was better and much more rapid than with the static machine. Dr. Bruce had found that the ten-inch spark coil was better than a 16-inch one for ordinary work. A third method of getting the current into the condenser was by raising the ordinary current of 450 volts to 55,000 volts by means of a "stepper." In utilising the current so obtained a "resonator" was made use of; the most convenient form of this was in the nature of a couch which was practically another Leyden jar, the patient forming one side and the indiarubber cushion representing the glass. Such high-frequency currents acted as a general tonic to the system as well as in lessening congestive conditions of the mucous membrane and relieving the pain of neuralgia, neuritis, and locomotor ataxia; in rheumatic arthritis even permanent relief might be obtained. In acute muscular rheumatism the relief might be almost immediate, as in the case of lumbago. In chronic rheumatism benefit also resulted. In neurasthenia the pains were often greatly relieved and a general improvement resulted. In hysteria, however, such a benefit was not obtained—even in some cases the pain had increased in severity. There was also good reason to hope that it might do good in some forms of muscular atrophy, especially if primary. In the treatment of most cases not only a local but a general improvement in health resulted. In alimentary diseases Dr. Bruce had noted a marked improvement in cases of dilatation of the stomach when due to atony or neurasthenia. In the acute stage hæmorrhoids rapidly improved, as did also fissure of the anus and pruritus ani. Severe cases of cardiac disease with degeneration of the heart muscle did not seem to be benefited. He had not had experience of the treatment in tuberculosis, gout, diabetes, or cancer.—Dr. BYROM BRAMWELL, Dr. GARDINER, Dr. A. D. WEBSTER, and Dr. J. O. AFFLECK took part in the discussion which followed.

Mr. DAVID WALLACE read a paper on Chronic Intestinal Obstruction caused by malignant stricture of the large intestine. The paper was based upon a series of ten cases which had been operated upon by Mr. Wallace during the past year. In eight of the ten cases the actual cause of the symptoms was a malignant annular constriction and in the other two this was also most probably present, though not absolutely determined. The condition was really a cylindrical-celled epithelioma which caused stenosis with a most characteristic appearance of the bowel at the affected part, as if a string had been tied round it, and producing an hour glass-like constriction. The new growth was very hard, small in width externally, but internally it was more spread out and fungating. The lumen of the tube was usually greatly narrowed even to the size of a crow quill ,the proximal portion of the gut generally underwent great dilatation and its wal'
whilst the gut on the distal
Though the disease must have l.
time, yet the patient may have had no other symptom than perhaps a gradually increasing degree of constipation. This insidious progress of the disease was most misleading and unfortunately might cause such delay that curative treatment became impossible. The ages of the patients varied from 47 to 82 years; six were females and four were males. As regards the site of the tumour five were situated at the splenic flexure, three at the hepatic flexure, and two in the iliac portion of the colon (sigmoid flexure). This is contrary to the usual statement that 60 per cent. of all strictures of the large intestine (including the rectum) are in the sigmoid flexure. In the hepatic and splenic flexures the tumours were by no means easily palpated as they lay deeply and high up. In a case of chronic obstruction in a patient at or above middle life with no tumour palpable through the abdominal wall or per rectum the commonest cause was an annular malignant stricture. A history of increasing constipation with perhaps general abdominal pain and some loss in weight was all that could be elicited. As regards treatment, even if the first acute attack of obstruction were got over by such means as liquid food and small doses of morphine and enemata, there remained the still greater risk of a second

attack which might end fatally or if operated on then the disease must have invaded further and the result must be less favourable. In Mr. Wallace's opinion there was only one reason for delay and that was the advantage of operating during a quiescent period. The operation was then much more favourable than if done when the bowel was full of liquid fermenting fæces. Three operative procedures were possible—(1) excision and end-to-end anastomosis; (2) short circuiting; and (3) colostomy. It was usually stated that as the disease was situated most often in the sigmoid flexure the incision ought to be made in the left linea semilunaris at the level of, or below, the umbilicus. In the ten cases narrated there was no sufficient warrant for such a position. The incision should be made through the right rectus close to the linea alba, just missing the umbilicus, and with its centre opposite the umbilicus. Such an incision allowed of easy examination of the seats of disease. It also allowed the surgeon to open the transverse colon if the disease was on the left, or if on the right an ileo-colostomy could be performed. If the tumour was removable a second incision should be made over the tumour. In all cases the first incision should be large enough to allow of easy access, and an artificial anus in this position was favourable for cleanliness, while the rectus acted as a fairly good sphincter. The first of the three procedures—namely, colectomy—was the most favourable, but it had usually to be done secondarily. A large portion of the colon might require removal to get suitable gut for union. Absence of tension at the sutured part was a first essential. To "short circuit" meant almost invariably the junction of the ileum to the colon, and the most favourable junction was that of the ileum to the transverse colon. After such operation the tumour underwent frequently a great diminution in size and the patient's life might be prolonged for years. Colostomy was the least desirable of the operative procedures. The part of the colon to open depended on the site of the tumour but the farther from the cæcum the better, as the after-comfort of the patient depended greatly on the solidity of the fæces. In the majority of cases the gut should be opened at the time of operation. The ten operations which were performed included two colectomies, three ileo-colostomies, and five colostomies. With the two colectomies one patient lived 13 months after the operation; the other died on the fourth day from peritonitis. The tumour in the latter was at the splenic flexure and was very adherent. With the three ileo-colostomies there were two recoveries and one death on the fifth day. With the five colostomies there were four recoveries and one death in a patient 65 years of age who was operated on when very ill.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Pathological Section.

Exhibition of Specimens.

A meeting of this section was held on Feb. 19th, Dr. H. C. **Earl** the President, being in the chair.

Mr. R. F. **Tobin**, in discussing some points in the Pathology of Senile Hypertrophy of the Prostate, said that the specimens of this condition which came under examination were usually of two kinds:—One, a smooth-surfaced, easily enucleated adenoma, often of large size; the other, commonly a smaller mass with a rough surface, and looking like muscular tissue to the naked eye, and containing in its centre the prostatic urethra, torn portions of which, or of the membranous urethra, hung out at one end. He then showed some recently removed specimens with regard to one of which he said that when his finger in shelling out the adenoma had reached its posterior surface and was still between the layers of the surgical capsule, it opened into a sac in which about a hundred calculi, varying in size from that of a grain of snipe-shot to that of a swan-shot, were lying free.—Dr. W. J. **Dargan** stated that the sections shown were made from the very outermost laminated layers of what seemed to be merely a fibrous envelope to the growth They showed here and there atrophic glandular spaces lined in many cases by cubical cells, but greatly compressed and evidently undergoing involution. The presumption was that these were derived from greatly compressed prostatic tissue.—The **President** said that he agreed that senile enlargement of the prostate was of a glandular nature. He had not always been able to find glandular or muscular tissue in the fragment of tissue adhering to the prostates removed by operation. In a number of examinations he had only once found a small myoma. He mentiond a case of prostatic obstruction due to a cyst in the left lobe.

Mr. K. E. L. G. **Gunn** showed a case of Endothelioma of the Peritoneum occurring in a man aged 28 years, with extensive secondary growths in the lung, the liver, and the bronchial glands.—Mr. E H. **Bennett** asked whether the primary growth had been found, as all the growths shown seemed to be secondary.—Mr. **Gunn** replied that the most careful search for a primary lesion had failed, and, acting on the presumption that the growth had originated from the peritoneum itself, it had been labeled an endothelioma.

Mr. **Gunn** also showed a Femoral Hernia in which a distinct Secondary Ovarian Growth had occurred. The ovarian tumour had been removed 19 years ago. The hernia had been enlarging for a few months before the operation.

Dr. **Neville** exhibited a Transplantation Cyst Tumour from the scar of an old (five years) ovariotomy. The tumour shown was of about the size of an ordinary fist and consisted of a congeries of small cysts, approximating 20 in number, varying in size from that of a pea to that of a large walnut. Microscopic examination showed a marked resemblance between the peculiar epithelium lining each cyst and that constantly found in Graafian follicles, the so-called membrana granulosa, specimens of which were shown.

The **President** showed a Teratoid Tumour of the Ovary. It was taken from a young woman who died with abdominal symptoms some months after its removal. Sections taken from different parts of the tumour showed small cavities lined by epidermis and having hairs and sebaceous glands in their walls. Other cavities were found to be lined with a columnar epithelium and glands resembling Lieberkühn's crypts opened into them. Bone, cartilage, masses of pigmented cells, adipose tissue, and tissue resembling that of the central nervous system were also found as well as groups of ganglionic nerve cells.

Society for the Study of Disease in Children.—A meeting of this society was held on Feb. 19th, Mr. R. Clement Lucas being in the chair.—Dr. Robert Hutchison showed a case of Progressive Cerebral Degeneration of the Family Type. The patient was a boy, four years of age, and was healthy until 10 months old when fits occurred on and off for some weeks. Two months ago he began to stagger when walking and he next developed some spasticity of the legs with mental apathy. The optic discs were becoming atrophic. There was another child in the family who became affected in the same way and at the same age. There was no history of syphilis.—Mr. J. Howell Evans showed a case of Symmetrical Bilateral Branchial Fistulæ with Symmetrical Bilateral Helical Fistulæ and Misshapen Aural Pinnæ.—Mr. J. Jackson Clarke showed an early case of Friedreich's Disease. The patient, who was a boy aged four years, had dropping of both feet, exaggerated knee-jerks, and Babinski's sign; the parents had also noticed some weakness of the left hand. A brother of the child had rigidity of the lower limbs and wasting of the muscles of the thumb. Symptoms began in his case at the age of six years. Mr. Clarke advocated in the early stages light instrumental guidance and afterwards tendon elongation and tenotomy followed by massage.—Dr. W. A. Wills and Mr. Douglas Drew showed a specimen of Secondary Angeio-sarcoma of the Lung. Mr. Drew removed the patient's left testicle for sarcoma in April, 1902, and there was no recurrence, local or general, until December, 1903. The case was thought to be one of empyema but when a rib was resected a new growth was discovered. Mr. Drew reminded the society that in the previous November he had exhibited the child as one of cure after removal of sarcoma of the testicle. On the last occasion on which he had seen the child Dr. Parkinson had found no evidence of disease in the lungs. The primary growth was adeno-myxosarcoma. The lung tumour resembled the primary growth in part but the rest of it was of the nature of angeio-sarcoma or endothelioma.—Dr. F Parkes Weber showed a case of Anæsthesia and Recurrent Ulceration of the Gluteal Regions from Spina Bifida.—Dr. George Carpenter showed Microscopic Sections of the Heart and Kidney from a case of Acute Œdema of the Lungs and Sudden Death. The case was diagnosed during life as one of uncomplicated myocarditis.

The urine was loaded with albumin, there were no patellar reflexes, and the soft palate was thought not to move freely. There was no history of diphtheria, but taking the clinical findings into consideration the condition was thought to be diphtheritic.—Dr. C. O. Hawthorne said that cases of sudden syncope after diphtheria were well known and Dr. Carpenter's case in all probability afforded a demonstration of the manner in which these disasters were produced.—Mr. J. P. Lockhart Mummery read a paper on the Treatment of Hernia in Young Children.—Mr. Lucas alluded to the special difficulty in young children of isolating the vas deferens from the sac.—Dr. Hutchison showed the Organs from a case of Hemi-hypertrophy. The patient was a healthy well-developed boy with three small capillary nævi in the skin. The left arm and leg were hypertrophied and to some extent the trunk was also. The asymmetry of the limbs was apparently due to an increase of the subcutaneous tissues of the left side resembling a diffuse lipoma. He subsequently developed an empyema and died. The increased thickness of the left limbs was entirely owing to an increased deposit of subcutaneous fat. The bones were normal. Most of the paired organs were decidedly larger on the left side than on the right. The left lobe of the thymus was larger but the two lobes of the thyroid were symmetrical.

GLASGOW NORTHERN MEDICAL SOCIETY.—A meeting of this society was held in the Maternity Hospital on March 1st.—Dr. J. M. Munro Kerr read a paper introducing a discussion on the Diagnosis and Treatment of Contracted Pelvis. He said that exact measurement was of less importance where the degree of contraction was either very slight or very great, as in the former forceps were applied and in the latter Cæsarean section was performed, but in cases of medium deformity accurate measurement was essential. Amongst the more accurate pelvimeters those of Skutche and Faulk might be mentioned. Another point of equal importance was the size and consistence of the child's head and there were many difficulties in arriving at this. It had been said that the fœtal head was the best pelvimeter and one mode of determining suitable treatment was to determine the relation of the head to the pelvis. This might be done by combining practically the methods of Müller and Pinard. With the right hand the accoucheur took the Pawlic grip of the head and pressed the head into the pelvis, while with two fingers of the left introduced into the vagina he felt how the head engaged, and at the same time with the thumb he felt all along the brim and estimated the degree of overlapping. By this method the chances of the head passing the brim, the degree of traction required, and the consistence of the head could be estimated. Objections which might be raised to the method were that an anæsthetic was necessary and that the presentation might be breech. As a matter of fact an anæsthetic was not always necessary and a breech presentation might be converted before the thirty-sixth week by external version. Where the disparity between the size of the head and the pelvis was slight delivery might be attempted in the Walcher position. It was difficult to fix a degree of deformity below which spontaneous birth was impossible. Thus in two cases a rachitic dwarf delivered herself without assistance, the child weighing seven and a half pounds on one occasion, her conjugata vera being three and a half inches. Forceps of the Simpson or Milne Murray type were the best; Walcher's position was an advantage; an anterior parietal presentation was the most favourable and the lowest limit for forceps should be a conjugata vera of three and a half inches, and then only if the head were not too large for the pelvis. Version was more dangerous to the mother and the fœtal mortality was much higher. Induction of premature labour would be the ideal treatment if the cases were seen at a sufficiently early stage; it was undesirable to induce premature labour before the thirty-fourth week. Dr. Kerr's method of examining the relative sizes of the pelvis and the fœtal head was demonstrated on an actual case.—Dr. John Ritchie, Dr. George B. Todd, and Dr. Robert Jardine took part in the subsequent discussion.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Feb. 16th, Dr. W. Milligan, the President, being in the chair.—Dr. A. T. Wilkinson opened a discussion on Uræmia and he applied the term as covering a group of nervous phenomena most frequently associated with definite renal disease. It was advisable to distinguish, at any rate mentally, this condition from imperfect excretion, actual or relative, of the final products of nitrogenous metabolism, urea and its allies. In other words, uræmia was not to be regarded as the culmination of urinary failure but as a variety of toxæmia which might occur with very different degrees of renal inadequacy. This view was applied in turn to acute uræmia occurring in inflammatory states of the kidney, in puerperal eclampsia, in acute uræmia with little or no urinary failure, and uræmia as it was seen in chronic Bright's disease. The key to the solution appeared to lie in the hands of those who could study puerperal eclampsia where uræmic phenomena occurred with very varied degrees of urinary failure. The morphine treatment here found efficacious might have to be modified considerably in dosage before it could be applied to all cases of uræmia, as in acute Bright's disease, when the special toxæmia was conjoined with general excretory failure. Saline injections which helped to dilute the poisons and to aid their excretion were frequently useful in the uræmia of organic disease, indeed general dropsy, if viewed as nature's treatment, authorised this method.—Dr. W. E. Fothergill said that he greatly appreciated the way in which Dr. Wilkinson had distinguished the actual effects of renal inadequacy from other nervous phenomena due to various forms of toxæmia which often occurred together with renal inadequacy. The term "uræmia" was doubtless loosely applied to both these sets of conditions, while it should strictly be limited to the former. He agreed with Dr. Wilkinson that the study of puerperal eclampsia, a condition now recognised as separate from renal disease, might in time throw valuable light upon the various conditions now known as uræmia.—Dr. E. Vipont Brown spoke of the ease and frequency with which uræmia was overlooked owing to the protean character of its manifestations. After referring briefly to several cases illustrating this point he concluded by saying that the general practitioner would do well always to bear in mind the possibility that any case he sees may be uræmic, however unlikely at first sight such a supposition may appear to be.—Mr. Burgess drew attention to the remarkable absence of symptoms of uræmia in cases of suppression of urine following upon complete obstruction of both ureters, usually by calculi—a circumstance which seemed to indicate that uræmia depended upon some other cause than merely the arrest of the excretory function of the kidney. In uræmia or threatened uræmia associated with acute nephritis, he advocated relief of the acute renal tension necessarily present therein by surgical measures—incision of the renal capsule and parenchyma followed by drainage—as a perfectly rational treatment and one destined to be much more frequently carried out in the future.—Dr. Wilkinson replied.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 4th, Dr. Leslie Durno, the President, being in the chair.—The President opened a discussion on Tonsillitis in which he expressed his belief in a bacterial cause and disbelief in the value of gargles.—Dr. B. G. Morison showed a Specimen and Microscopic Section of a Mammary Cyst removed from a woman, aged 80 years. The skin over the cyst was red and so operative interference became necessary. On part of the cyst wall were villous growths similar in structure to those found in the bladder.

Reviews and Notices of Books.

Bacteriology of Milk. By HAROLD SWITHINBANK and GEORGE NEWMAN, M.D., F.R.S. Edin., D.P.H. Cantab., Medical Officer of Health of the Metropolitan Borough of Finsbury and formerly Demonstrator of Bacteriology in King's College, London. With Special Chapters also by Dr. NEWMAN on the Spread of Disease by Milk and the Control of the Milk-supply. London: John Murray. 1903. Pp. 605. Price 25s. net.

THIS book, which represents the first attempt that has been made to deal comprehensively with the bacteriology of milk and with the part taken by milk in the spread of disease, is one that will fill substantially a space in the medical library which has been left vacant for too long a time. Moreover, the authors may be justly congratulated on the result of their endeavour to place at the service of medical officers of health and others who are interested in the matter a compendium of what is known at present of milk, whether as a food or as a means for the conveyance of disease. In accordance with the title the contents of the book may be considered in two sections. The first part, for which the writers are jointly responsible, deals with the chemical composition and the bacterial contents of milk, with technical details to be followed in its bacteriological examination, and with the fermentation processes which occur in milk and their economical import in industrial processes. The portion of the book for which Dr. Newman is alone responsible includes most valuable chapters on epidemics, either milk-borne or alleged with more or less reason to be so, and with the measures enforced by the State and adopted by private individuals with the object of insuring the purity of our milk-supplies. In the earlier pages of the book the writers give a detailed description of the technique which they have found most useful in the examination of milk and add the main results of their own extensive investigations into the natural rate of increase of bacteria in milk and cognate matters. A full descriptive catalogue is also given of the morphological, cultural, and other characteristics of the very numerous species of micro-organisms which are likely to be found in milk. Whilst this portion of the book is mainly for the bacteriologist, the special chapters by Dr. Newman on the influence of milk in the spreading of disease will be read with interest by all medical men and by the medical officer of health in particular. Dr. Newman deals first with the question of the conveyance of bovine tuberculosis by means of infected milk and after fully considering all the well-ascertained facts bearing on this matter he comes to the conclusion that at present it is not possible to gauge accurately the degree of danger to man arising from the use of milk from tuberculous cows, but taking a broad view of these facts he holds that "whilst tuberculosis is not chiefly spread by means of milk, there is unmistakeable evidence, derived from pathological and clinical experience, proving that tuberculous milk can, and does, set up some form of tuberculosis (bovine or human) in the bodies of man and other animals consuming the milk."

Careful consideration is next given to the question of "milk-borne" epidemics of the three important zymotic diseases—scarlet fever, typhoid fever, and diphtheria; the special characters of such outbreaks are referred to and numerous well-authenticated examples are given in detail of epidemics in which no probable cause other than a milk-supply could be found. Whilst there can be no question that such epidemics are, and not infrequently, caused by contaminated milk, the question as to whether the milk has become infected primarily because of similar disease in the cow or accidentally from some extraneous human source is one of more than merely academic interest in preventive medicine. An analysis of Dr. Newman's collection of recorded epidemics has led him to the conclusion that up to the present time the evidence forthcoming points in the direction of human rather than bovine infection and that when milk is apparently the cause of an epidemic of one or other of these diseases accidental contamination from a human source rather than disease of the cow supplying the milk is the cause which is to be sought for.

Taking the three diseases in detail we find that in 64 epidemics of typhoid fever caused by milk-supplies contamination from a human source was probable in 62, whilst in two epidemics no probable source of contamination of the milk could be found. With regard to "milk borne" epidemics of diphtheria the evidence is less conclusive. Dr. Newman quotes details of 18 outbreaks alleged to be due to a milk-supply; in these there was a probable source of human contamination in ten instances, in three instances no probable source of contamination of the milk could be found, and in the remaining five epidemics cows contributing to the milk-supply were found to be suffering from lesions of the udder. In none of the cases in which the cows were found to be suffering from lesions of the udder was there any proof that the disease was of such specific nature as to be a cause of diphtheria in man and Dr. Newman states that there are only four well-authenticated cases in which the bacillus diphtheriæ has been found in a suspected milk in spite of the very numerous occasions during the last few years on which milk which has been suspected of being the cause of an outbreak of diphtheria has been submitted to bacteriological examination. Dr. Newman gives details of 40 epidemics of scarlet fever in which suspicion was directed to the milk-supply. In 28 outbreaks there was good reason to believe that the milk might have been contaminated from a human source, in three cases no probable source of contamination of the milk could be discovered, and in the remaining nine cases the probable source of infection was held to be disease in the cow. Dr. Newman referring to the case of the classical "Hendon disease," considers that the existence of "cow scarlatina" has not as yet been definitely established. In addition to outbreaks of well-defined disease which have been attributed to milk-supplies, many instances of epidemics of "sore-throat" attributed to a similar source are quoted and the relation of milk to epidemic diarrhœa is fully discussed. Three chapters on the Control of the Milk-supply—(1) by the State, (2) by private enterprise, and (3) by the trade—conclude the volume.

In this review we have only indicated some of the more important matters dealt with by the authors but we can cordially recommend a careful perusal of the whole book to such of our readers as are specially interested in public health matters.

Disinfection and the Preservation of Food. By SAMUEL RIDEAL, D.Sc. Lond. Third Edition. London: The Sanitary Publishing Co., Limited. 1903. Pp. 494.

THE second edition of this useful and authoritative work was reviewed in THE LANCET of Dec. 31st, 1898, p. 1769. Since that time, of course, certain progress has been made in this branch of sanitary science and Dr. Rideal himself has gained considerable experience on special points, while he has been connected with researches on disinfectants and food preservatives which have yielded important results. From time to time he has communicated some of these results in our columns. We observe that the title of the present edition is "Disinfection and the Preservation of Food," instead of as heretofore "Disinfectants and Disinfection." The question of the use of preservatives in food has been brought prominently under public observation by the inquiry instituted some years ago by the departmental committee. We have expressed the opinion that the recommendations which this committee drew up were on the whole satisfactory and the delay in putting them into effect is serious and blameworthy. At present this country is without any special statute applying to the control of the use of preservatives in foods. Dr. Rideal remarks that it would seem impossible under modern conditions of life to do without some methods of keeping perishable articles of food without incurring a very large loss and it cannot be denied that with proper safeguards in some instances even chemical treatment may be desirable. The country is awaiting the action of a far too dilatory Government in order that these safeguards may be provided. The chapters dealing with the various proprietary disinfectants are of great interest and practically embody a history of the subject. The chapter on methods of analysis is of decidedly practical value and should serve as a trustworthy guide to those concerned in determining the actual germicidal value of disinfectant preparations. Here, again, it seems to us that interference by legislation is needed in regard to the control of the sale of disinfectants. There are many worthless preparations on the market possessing little or no germicidal efficiency at all. Dr. Rideal has suggested that in making a germicidal determination pure phenol might be adopted as a control standard and the strength or efficiency of the disinfectant might conveniently be expressed, he thinks, in multiples of carbolic acid performing the same work. When, for example, a dilution of the disinfectant is obtained which does the same work as the standard carbolic acid dilution, the former is divided by the latter and a ratio termed the carbolic acid coefficient is thus found. We have dealt sufficiently with this new edition of the work to show the directions in which it will serve as an undoubted guide and as a source of instruction. The subject is most important and Dr. Rideal's contribution to it will be thoroughly appreciated by all those concerned not only in broad sanitary measures but in surgical science also.

LIBRARY TABLE

The Phase Rule and its Applications By ALEXANDER FINDLAY, M.A., Ph.D., D.Sc., Lecturer and Demonstrator in Chemistry, University of Birmingham. London. Longmans, Green, and Co. 1904 Pp. 313 Price 5*s.*—Physical chemistry is growing apace and the results accruing from its study are of the most important kind. In many instances it is difficult to draw an exact line between physics and chemistry, but under the heading of physical chemistry would be included those considerations in which the laws or generalisations regarding properties of matter depend not merely on the masses or rates of motion of the objects studied but also on their composition and chemical nature. It is obvious from this definition that a very wide field for study is presented to view, a study which will be much facilitated by the issue of the series of volumes now promised by the above publishers, each of moderate compass and each dealing with one branch of the subject. Sir William Ramsay has written an admirable and historic essay and introduction to the whole series, the first of which is the book before us on Phase Rule. Next will be dealt with in future volumes, "Stoichiometry," "The Relation between Chemical Constitution and Physical Properties," "Electro-Chemistry," "Spectroscopy," "Thermodynamics," and, lastly, "Chemical Dynamics and Reactions" The publication of this series marks the first attempt to present the subject in concrete form and to consolidate the contributions regarding physico-chemical matters which are scattered throughout a number of scientific journals. In the interests of medicine we welcome this step since we must recognise the importance of physical chemistry in its relations to physiological problems. The Phase Rule deals with the study of the changes in the equilibrium existing between different substances It defines the condition of equilibrium by the relation between the number of co-existing phases (ice, water, and vapour are three phases of the same substance) and the components (hydrogen and oxygen are considered as components but not constituents when by raising temperature to a certain point a state of true equilibrium between hydrogen, oxygen, and water vapour will be possible) The Phase Rule may thus be stated (p. 16): "A system consisting of *n* components can exist in *n* + 2 phases only when the temperature, pressure, and concentration have fixed and definite values; if there are *n* components + 1 phases equilibrium can exist while one of the factors varies, and if there are only *n* phases, two of the varying factors may be arbitrarily fixed." By the application of this rule it has been not only possible to render "the grouping together of a large number of isolated phenomena but the guidance it affords has led to the discovery of new substances, has given the clue to the conditions under which these substances can exist, and has led to the recognition of otherwise unobserved resemblances existing between different systems." Dr. Findlay in the preface states that the exposition of the Phase Rule and its application given in the text have been made entirely non-mathematical. The study of this subject is not simple and the busy medical practitioner could hardly be expected to devote more time to it than, say, the study of astronomy, though the importance of the Phase Rule to medical science cannot be doubted.

The Four Epochs of Woman's Life: A Study in Hygiene. By ANNA M. GALBRAITH, M.D. With an Introductory Note by JOHN H. MUSSER, M.D., Professor of Clinical Medicine, University of Pennsylvania Second edition, revised and enlarged. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 243 Price 6*s.* 6*d.* net.—This book is designed to teach in popular form "the fundamental principles which underlie the various epochs" of woman's life (maidenhood, marriage, maternity, and the menopause) Professor Musser in a brief introductory note gladly commends the essay and says that the truths which it contains "should be known by every woman." It will be readily admitted that the subject is one which requires very delicate handling and although portions of the book are excellent there are others which might judiciously have been omitted.

The Prescriber's Pharmacopœia. Fifth edition. Bombay and London: Kemp and Co. 1904. Pp. 373.—This admirably compiled synopsis of the more recent remedies, both official and unofficial, is published by a firm of wholesale and manufacturing chemists and druggists of Bombay. The fact that it has reached a fifth edition shows that it is widely appreciated. We have carefully looked through the pages, which are well printed and arranged, and we find that the list of drugs given is very complete and in a line with recent developments. The index is particularly well done and the whole arrangement is such as to facilitate the work of reference. The preparations noted in the Indian and Colonial Addendum of the British Pharmacopœia are included. Students and practitioners of medicine in India may be congratulated upon having such a complete pharmacopœia at their disposal. It may easily take rank with English standard works on the subject.

A Guide to Urine Testing for Nurses and Others. By MARK ROBINSON, L R C.P., L R C.S. Edin. Bristol: John Wright and Co 1904 Pp 56. Price 1*s.* net.—This little book will be found very useful to the persons for whom it is written. It gives a short account of normal urine together with the various departures from the normal which may appear. Fallacies in testing are then noted, after which a description of the apparatus used in testing is given. The rest of the book is taken up with an account of the different substances to be tested for together with the methods of recognising their presence. Microscopical examination of the urine is purposely omitted as being beyond the scope of the work.

Dispensing made Easy. By W. G. SUTHERLAND, M.B. Aberd. Bristol: John Wright and Co. 1904. Pp. 102. Price 3*s* 6*d.*—Dr. Sutherland's little book if carefully studied will certainly lighten the labours of the country practitioner. It does not pretend to teach the *haute école* of dispensing, such as the making of emulsions and the coating of pills, but it is full of practical hints and of ways in which to combine economy with efficiency. It would be well, we think, in a future edition to add to "Points worth remembering" the fact that bromides and iodides dispensed with alkaloids cause these latter to precipitate.

JOURNALS AND MAGAZINES.

The Medical Magazine.—The February number of this magazine contains a sensible article by Mr. J. Foster Palmer upon the *rationale* of certain so-called drink cures. Mr. Palmer puts forward a clear classification of the various kinds of person subject to habitual drunkenness and shows in what cases there may and in what there may not be logical expectation of permanent benefit. He demonstrates the extremely transient nature of the change which is in too many instances vaunted as an example of "cure" and goes somewhat fully into the use of hypnotic suggestion as a remedy. In another article the use of Somnoform is described with various practical hints referring to methods of administration, after-effects, and cost. The author fails, however, to point out that almost identical and equally good results can be obtained by the use of pure ethyl chloride as a general anæsthetic. Ethyl chloride is the main constituent of somnoform and there is no valid reason for preferring to the pure drug a proprietary article with a fanciful name and an evil smell. In both cases there are strict limitations to be observed in the employment of the drugs for purposes of general anæsthesia, limitations which in the first attraction of a "new" and much belauded agent are apt to be overlooked.

Journal of the Irish Medical Association.—The principal contents of the March number are an account of the business transacted at the meetings of the council of the Irish Medical Association and a series of reports received from the various branches of the association. These reports are for the most part records of the work accomplished in connexion with increasing the remuneration and generally improving the position of the dispensary medical officers in the Poor-law service. It is well known that the association has frequently intervened with good effect in cases where inadequate salaries have been offered by boards of guardians and where an absence of cohesion among the members of the profession threatened to defeat efforts which were being made to obtain better terms. The editorial articles criticise recent proposals for altering the present systems of vaccination and death certification.

Analytical Records

FROM

THE LANCET LABORATORY.

PROTENE FOODS.

(THE PROTENE CO., LIMITED, 36, WELBECK-STREET, CAVENDISH-SQUARE, LONDON, W.)

THE above company was amongst the first in this country to employ the separated and dried proteid of milk in the preparation of foods by which their nutrient value was of course considerably enhanced. Some years ago we submitted several of these foods to analysis, the results showing in all cases a decidedly increased proteid value. Some important additions to the protene preparations have recently been made, samples of which have been submitted to us. We may refer to protene bread which gave us the following results of analysis: moisture, 43·48 per cent; mineral matter, 3·04 per cent.; proteid, 36·08 per cent.; and non-nitrogenous matter, 17·40 per cent. Excluding moisture the bread would thus contain over 60 per cent. of proteid. According to the iodine test this bread is free from starch; it is thus suitable for the use of patients suffering from diabetes and other persons to whom it is an advantage to eat sparingly of food rich in carbohydrate. The texture of the bread is uniform and good. We have also examined "Alma biscuits" which similarly are free from starch whilst containing less fat than some of the other special food preparations. The "Welbeck biscuit" is a well-made and palatable biscuit containing about 25 per cent. of proteid. Lastly, protene cocoa gave, according to our analysis, the following results: proteid, 41·45 per cent.; fat, 22·50 per cent.; non-nitrogenous matter, 23 55 per cent.; mineral matter, 6·50 per cent.; and moisture, 6·00 per cent. According to this analysis the cocoa consists, roughly, of equal parts of cocoa and protene.

ALGERIAN BRANDIES.

(SOUTHARD AND CO., 2, ST. DUNSTAN'S-HILL, LONDON, E.C.)

We have submitted specimens of three vintages of this brandy to analysis and the results are perfectly consistent with those yielded by genuine wine spirit. The brandy of vintage 1900 gave the following results: extractives, 0·62 per cent.; mineral matter, 0·02 per cent.; and alcohol, by weight 50·09 per cent., by volume 58·92 per cent., equal to proof spirit 101·51 per cent. As regards secondary products the following were the results expressed in grammes per 100 litres absolute alcohol present: volatile acidity reckoned as acetic acid, 40·80; aldehydes, 17·00; furfural, 1·10; ethers reckoned as ethyl acetate, 62·73; and higher alcohols, 170·00. The sample of the vintage 1901 gave the following results on analysis: extractives, 0·68 per cent; mineral matter, 0 02 per cent.; and alcohol, by weight 49·16 per cent., by volume 56·98 per cent., equal to proof spirit 99·86 per cent. The secondary products were found to be as follows given in grammes per 100 litres of absolute alcohol present: volatile acidity reckoned as acetic acid, 40·80; aldehydes, 8·50; furfural, 1·10; ethers reckoned as ethyl acetate, 47·60; and higher alcohols, 85·00. The sample of vintage 1902 gave the following results on analysis: extractives, 0·54 per cent.; mineral matter, 0·01 per cent.; and alcohol, by weight 50·52 per cent., by volume 58·36 per cent., equal to proof spirit 102·28 per cent. The secondary products given in grammes per 100 litres of absolute alcohol present were as follows: volatile acidity calculated as acetic acid, 30·60; aldehydes, 8·50; furfural, 0 85; ethers reckoned as ethyl acetate, 55·35; and higher alcohols, 85·00. These figures coincide with those obtained with genuine though somewhat young brandies. The alcoholic strength shows that all these brandies have not been reduced to a strength suitable for consumption. There is no doubt that they would improve with age and develop a finer bouquet and flavour than they exhibit at present. Compared with average Cognac brandies the ethers are decidedly low. These Algerian brandies consist of spirit derived entirely from the grape. The test, both of palate and of analysis leads to this conclusion.

"FERRUBRON" PAINT.

(THE "FERRUBRON" MANUFACTURING CO, LIMITED, 143, QUEEN VICTORIA-STREET, LONDON, E C.)

Ferrubron paint has for its basis a substance which is entirely different from lead or zinc compounds. As a matter of fact the basis consists of a native peroxide of iron. It is a glistening mineral, having the beautiful lustrous appearance of native antimony. The pigment made with it possesses good covering power and on drying leaves a uniform silvery film. It does not appear to tarnish. Of the shades submitted to us we have the most favourable opinion of the silver-grey. The paint is absolutely non-poisonous. Its permanency as regards its peculiar metallic lustre is a valuable feature of ferrubron paint. It withstands heat and may be used for radiators or for painting metal surfaces of stoves or laboratory and hospital appliances. It beautifies all metal work and should prove to be a sanitary adjunct in the hospital ward or operating theatre, for while it is durable the finished paint is washable and presents a clean and attractive appearance.

DROITWICH BRINE CRYSTALS.

(WESTON AND WESTALL, LIMITED, 41, EASTCHEAP, LONDON, E.C.)

This salt is obtained by the evaporation of Droitwich brine which, as is well known, is used in the form of a bath for the treatment of rheumatic affections. The evaporated salt occurs in small cubes and on analysis it gives the following results: sodium chloride, 96·23 per cent.; calcium chloride, 0·055 per cent.; sodium sulphate, 0·09 per cent.; and moisture, 3·60 per cent. The crystals are contained in bags holding 14 pounds. In preparing the salt bath two pounds of the salt are dissolved in each gallon of water. In addition to the use of this salt for rheumatic affections it may be advantageously used in the preparation of the artificial effervescing Nauheim bath.

SANGUINOSA.

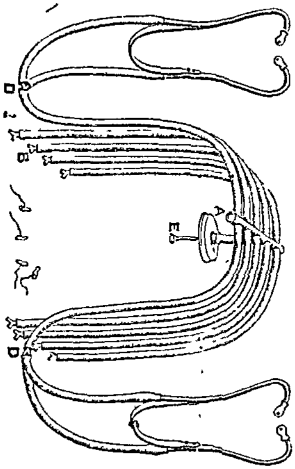
(THE SANGUINOSA CO., 79, MARK-LANE, LONDON, E.C.)

Sanguinosa is described as "The Vegetable Invigorator" and according to our analysis and examination it has the composition and character of a red wine. The analysis was as follows: alcohol, by weight 12·38 per cent., by volume 15·30 per cent., equal to proof spirit 26·82 per cent.; extractives, 2·94 per cent.; mineral matter, 0·370 per cent.; volatile acidity reckoned as acetic acid, 0·096 per cent.; fixed acidity calculated as tartaric acid, 0·20 per cent.; and sugar, 0·124 per cent. The preparation is stated to possess value as a tonic on account of the organic iron present. This iron amounted according to our analysis to 0·01 per cent. reckoned as ferric oxide. The preparation thus contains *no more iron than is found in many red wines* of the burgundy type. We doubt whether sanguinosa is of any value as regards its iron. Generally speaking, there is much nonsense talked about the value of small quantities of iron in wine when as a matter of fact there is much more iron contained in the daily average diet than in a dozen bottles of wine of the so-called *ferruginous type.*

New Inventions.

A MULTIPLE STETHOSCOPE.

THE idea of arranging a stethoscope so that several students can listen to a patient's chest at the same time is a good one; unfortunately, the contrivances hitherto introduced have not proved successful. We submitted the instrument under consideration, which has been designed by Dr. W. G. Aitchison Robertson, to a trial before a class of students but the result was not satisfactory. The sounds were not heard nearly so distinctly as by means of the ordinary binaural stethoscope. The apparatus could be improved by making the Y-shaped metal pieces which are inserted into the ends of the rubber tubes larger; the tubes attached to the students' *stethoscopes* were all too large to grasp the attachments firmly. The illustration clearly shows the construction of the stethoscope, which is made by Mr. T. Hawksley, Oxford-street, London.



A, Supporting piece for tubes. B, One of the Y-shaped pieces to which ordinary stethoscope tubes can be attached as at *D*. *E*, *Chest-piece and phonendoscope.*

AN IMPROVED PORTABLE OPERATION TABLE.

THIS table is so constructed that it can readily be adjusted to the usual positions required. It is thoroughly substantial and rigid in each position and capable of supporting a weight of 20 stones; it can be folded into a comparatively small compass for carrying in a canvas case or satchel; it always folds up accurately and there is no likelihood of its being strained or bulged. When it is in its case it is not too heavy to move about with one hand. Its mechanism is so simple that it can be placed in the desired position or folded and put away in less than two minutes. It can be made in wood, polished or enameled, or in metal, nickeled or enameled, and is comparatively inexpensive. As shown in Fig. 1, it consists of a horizontal frame hinged in the centre; the legs and struts are also hinged and the cross laths of the table are so constructed that the whole falls accurately together. The Trendelenburg position, as shown in Fig. 2, is secured by lifting the table in the centre and is maintained by a strut secured with thumbscrews. By a rack arrangement the portion corresponding to the upper position of the body can be raised to any position from the horizontal to the erect. If desired, a pair of crutches for the lithotomy position can be affixed to the lower end.

FIG. 1.

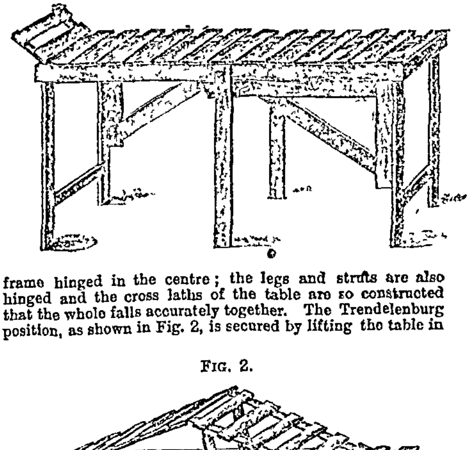


FIG. 2.

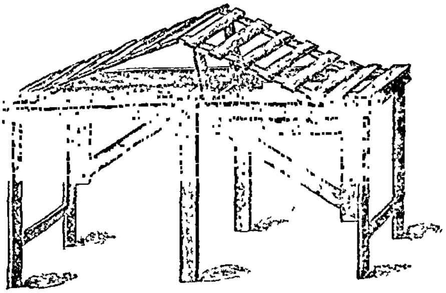

Messrs. Arnold and Sons of West Smithfield, London, E.C., have made the table at my suggestion and after 12 months' use I find it in every way satisfactory.

J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.

Kidderminster.

THE LANCET.

LONDON: SATURDAY, MARCH 12, 1904.

The Health of the Navy.

HAVING regard to our late experiences in South Africa and the striking events that have still more recently focussed public attention on the naval operations in the Far East it is no wonder that an unusual degree of interest should just now be taken in all that concerns the naval and military services of this country. The sweeping and radical reforms proposed by the War Office Reconstruction Committee and the debates in connexion with the navy and army estimates have also served to rivet public attention on these services at the present time. We are passing through a transition stage and from whatever side matters are regarded it is clear that the nation is confronted with many questions of vital importance about which it will shortly have to make up its mind. Let the political views be what they may, there is a side from which the maintenance of efficiency in both peace and war must be approached and considered—namely, that of health and hygiene. This is a matter of growing importance which can never be lost sight of and it is one, moreover, which no Government can afford to ignore. We are led to these reflections from the fact that at the present moment we have before us the Statistical Report of the Health of the Royal Navy for 1902 and that, as regards the army, we must be content to remain in ignorance of what is proposed to be done with its medical service until Part III. of the War Office Committee's report is published.

In THE LANCET of March 5th, p. 680, we briefly called attention to the Statistical Report of the Health of the Royal Navy. We may here add that, according to that report, the ratio of cases per 1000 of force for 1902 shows a reduction on all stations except the Home and the East Indies; that the invaliding ratio of the total force also shows a decrease (the highest invaliding-rate was on the Cape of Good Hope and West Coast of Africa station); and that the death-rate, which was 5·92 per 1000 for 1902, showed a slight decrease when contrasted with the last five years' ratio. The highest death-rate appears on the Pacific station, due to the unfortunate loss of the *Condor* and not to medical reasons. But it is not so much the purely statistical part of the report that will hold the medical reader's attention. Statistics can scarcely be styled a form of light literature and we do not find that even those deeply concerned in a subject are much prone to argument about arithmetical tables, however germane to the topic, but there are several interesting and significant papers in the appendix to this report for 1902 which claim consideration at the present time. There is no more difficult problem, for example, than that of the treatment of wounded in action on board a modern battleship, which forms the subject of a carefully thought out article by Fleet-Surgeon P. B. HANDYSIDE of H.M.S. *Vengeance*. Accepting the view of those familiar with the construction of a modern battleship and the requirements of modern surgery that it would not be possible during an action to remove wounded men to a place of safety below the waterline or armoured deck and there to perform surgical operations, Fleet-Surgeon HANDYSIDE proceeds to discuss very carefully and from a practical standpoint what can be done and what are the duties of medical officers before, during, and after a naval action. Of course, the object aimed at in our modern warships is to make them the most perfect fighting machines possible, but that is no reason why the attempt should not also be made to secure the best hygienic arrangements attainable in the circumstances. Moreover, we are not happily always at war and naval engagements do not last long when we are. It consequently appears to us that a naval medical officer might be usefully consulted in matters of naval construction and plans. We refer our readers to Fleet-Surgeon HANDYSIDE'S contribution to the blue-book under notice as showing the value of hearing a medical opinion upon such matters.

All who are interested in the genesis and evolution of the Royal Navy Medical Service, naval hygiene, and the internal economy of His Majesty's navy will turn to "Notes and Extracts from Journals" extending from 1793 to 1856 compiled by Deputy Inspector-General T. J. PRESTON. Like all stories worth the telling, the moral to be drawn from this paper lies on the surface, and that moral is that the navy has steadily progressed in matters medical and hygienic. We may regret that the extracts from the journals are so short and scanty, such mere samples, that they only whet the appetite for more, but sufficient evidence is marshalled to prove the proposition. The medical, bacteriological, and other papers in the appendix to the report strike us as being unusually good and the results obtained in some of the surgical cases recorded reflect great credit on the medical officers concerned. We may conclude with what we desire to emphasise—viz., the contrast which exists between the conditions affecting the Royal Navy of the present day as compared with those which obtained in 1793–1856 for example, to take the date dealt with in Deputy Inspector-General PRESTON'S interesting communication. The advances that have taken place in naval hygiene, applied medical and sanitary science, and we may say in every respect, have been great and mainly in proportion to the increased and increasing position and influence of the medical service. This is a thing worth noting by our readers, especially by those who have the education of medical students in their charge. It may be possible, indeed it may be easy, to pick holes in the Royal Navy Medical Service, but it is a service of great possibilities and promise.

◆

The Medical Officer of Health: His Report and his Sanitary Authority.

A RECENT meeting of the Newbiggin (Northumberland) district council has revealed a misapprehension upon the part of the council with regard to its own duties and the position and duties of its medical officer of health, which deserves some serious notice, if only to furnish arguments for those who would prevent other sanitary authorities from falling into the same error. It appears that the medical officer of health of the district, Dr. VINCENT BURROW, had at a previous meeting submitted his annual report, when the council had taken the significant step of referring it back to him in order that he might delete or alter portions with which the council did not agree. This the medical officer of health of course refused to do. At a subsequent meeting of the council held on March 2nd Dr. BURROW pointed out that it was his duty to make his report as to matters which, in his opinion, were unsatisfactory within his district and to do so without regard to the views of the council. He further pointed out that were the report to be made under the conditions which the council sought to impose upon him it would become the council's report instead of that of its medical officer and he firmly refused to forfeit his self-respect and the respect of the council by deleting or altering any portion of what he had written, since he believed that all the report was accurate and necessary. Even then the members of the council did not apparently appreciate the position in which they were placing themselves, for the subject was further discussed until the clerk of the council, on being appealed to, gave the only possible opinion that the medical officer of health was bound to submit his report and that the council had absolutely no control over it. The medical officer of health will therefore have his way and will be allowed to present his report ungarbled. So far all is well, but the episode provides food for serious reflection. The same situation has arisen in other places and it is to be hoped that a little ventilation of the matter may prevent sanitary authorities from stultifying themselves in the future in a similar way. That a local sanitary authority should apply, or should attempt to apply, pressure to the medical officer of health is, apart from the insult to him contained in the suggestion that he might be found willing to yield to such pressure, a matter of prime public importance. Newbiggin may not rank among the great English watering-places but none the less what has happened there may happen elsewhere. Newbiggin, with a population of a little over 2000 inhabitants, is under the care of an urban district council but the Acts of Parliament which govern it are the same as those which apply to other localities and its medical officer of health, no doubt, occupies a similar position to that of many others who are not independent of the necessity for private practice. That position in a small district even more than in a large one has the disadvantage that attempts to influence its occupant, which cannot be made publicly without attracting attention, can there be brought to bear in private with greater ease. The medical officer of health, as is well known, has to furnish every year primarily to the sanitary authority a report of the district under his charge but he has also to send copies of that report to the Local Government Board and to the county council. With regard to these the Local Government Act, 1888, provides that "If it appears to the county council from any such report that the Public Health Act, 1875, has not been properly put in force within the district to which the report relates or that any other matter affecting the public health of the district requires to be remedied the council may cause a representation to be made to the Local Government Board on the matter." That is to say, the report of the medical officer of health is for the *information of the* Local Government Board and county authorities and is quite useless unless it is a straightforward and ungarbled document. There are, no doubt, many sanitary authorities the members of which would be glad if the drawing-up of the report upon the hygienic plight of the community for the information of such critics as the Local Government Board and the county council were to be intrusted to them and not to the medical officer of health. The legislature has, however, thought differently and in the interest of the public has intrusted the responsibility for such reports to men who are qualified by their professional training to make them efficiently and who will uphold the traditions of their profession by making them honestly. We commend the action of the Newbiggin district council to the attention of the Northumberland county council and of the Local Government Board. The latter body must know as well as we do that attempts to persuade the medical officer of health to water down an inconveniently outspoken report have occurred before. Such a misapprehension as has arisen in one place as to the relative positions of the council and the medical officer of health may arise in another. The Local Government Board has power to prevent such recurrence by intimating to local authorities that pressure or persuasion of any kind whatever put upon medical officers of health in order to induce them to issue "faked" reports will be viewed by the Board with grave displeasure.

The Etiology of Hernia.

MR R HAMILTON RUSSELL took the Congenital Origin of Hernia as the subject of his presidential address to the Medical Society of Victoria, Australia, on Jan 6th and worked out his theory of their congenital origin more elaborately than on any previous occasion. We publish his address, but little abbreviated, on p. 707 of this issue of THE LANCET.

The question of the mode in which a hernia is formed has long exercised inquiring minds but it can hardly be said that we have yet arrived at finality. The earliest opinion held is shown by the names given in popular language to the lesion, as in English the word "rupture" expresses the idea of a breaking forth of the bowel from within the abdomen. The German word "Bruch" is of similar meaning and the same idea is found in many languages. The name seems to imply that the chief cause is excessive pressure within the abdomen and even our present knowledge justifies us in saying that whatever may be the predisposing and assisting conditions a marked increase in the intra-abdominal *pressure is probably responsible for a very* large proportion of the herniæ seen. In very many cases there is a definite history of coughing or straining having immediately preceded the development of the hernia. Yet it must be recognised that contributory conditions must be present before a hernia can be formed. The first and most obvious suggestion is that the abdominal wall has been abnormally weak at the place where the hernia appears and that this local weakness is a real adjuvant in the production of a *hernia* is seen in the formation of traumatic herniæ; for instance, a laparotomy has weakened the abdominal wall by section of its ligamentous and muscular fibres with the result that the injured tissues are unable to resist even the normal pressure existing within the abdomen and a hernia results. That weakness is probably of etiological importance in other herniæ also is shown by the fact that they occur in certain well-defined spots where there is a loss of continuity of one or more structures forming the parietes of the abdomen. At the deep inguinal ring the wall is *evidently defective for the purpose* of allowing the spermatic cord to pass through. It is true that arrangements have been apparently specially made to minimise the risk of a hernia, for the two inguinal rings are not opposite one another and the abdominal pressure tends to keep together the anterior and posterior walls of the inguinal canal. The crural ring is so patent that it seems to invite a hernia and the umbilicus, too, is evidently a weakened spot. Thus it is true of the usual forms of herniæ that they occur in sites where the abdominal parietes are for one cause or other less strong than elsewhere. This is also true of the rarer herniæ, such as obturator hernia and that occurring through Petit's triangle in the interval between the latissimus dorsi and the external oblique muscles. In spite of these important and obvious facts it must be acknowledged that the etiology of hernia is not so simple of determination as it would appear to be, for weakness of the abdominal wall, even when accompanied by an excessive pressure from within, will not suffice to explain the occurrence of the vast majority of herniæ. It is a remarkable fact that if in the dead body the abdomen is opened and an attempt is made to produce a hernia by pushing the bowel through one of the usual hernial apertures it will nearly always be found impossible to bring the bowel down sufficiently, for the mesentery is rarely long enough to permit the bowel to pass through the deep inguinal ring or the crural ring. When this fact was first observed it was thought that a great predisposing cause of hernia was an unduly long mesentery. Time has not confirmed the importance of the length of the mesentery. In the living body the extensibility of the mesentery is probably far greater than post mortem, and when other conditions are favourable the shortness of the mesentery will not serve to prevent the formation of a hernia. We may therefore put aside as comparatively unimportant the length of the mesentery. What further condition have we to offer as predisposing to the production of a hernia? It is clear that in the condition which is usually known as a "congenital inguinal hernia" a structure is present which must assist immensely in the production of hernia; we find a sac already formed, the processus vaginalis. The frequency of this variety of hernia in infants proves clearly the very great assistance that this gives in the formation of hernia. Mr. Russell accordingly advocates the idea that all, or almost all, herniæ are "congenital" in origin—that is to say, that the bowel always finds waiting for it a sac which has existed from birth. This opinion he first advanced in 1899 and in several papers since he has elaborated the idea and applied it to herniæ to which, at first, it did not seem applicable. Thus he explains femoral hernia as resulting from the existence of a sac arising at an early stage of development, when the limb buds are being formed; as a limb bud arises he suggests that a diverticulum of the pleuro-peritoneal cavity is, as it were, drawn into it. The many varieties of inguinal hernia owe their origin, according to Mr. Russell, to corresponding varieties of sacculation of the peritoneal pouch. Thus he accounts for the interstitial and properitoneal herniæ by supposing that a portion of the descending peritoneal sac has become caught by the developing abdominal wall and he looks upon the connexion of an interstitial hernia with an imperfect descent of the testis as the *associated results of a* common developmental cause.

There seems to be a difficulty in explaining a direct inguinal hernia by this theory, but Mr. Russell has met with a case in which there was a peritoneal pouch in the situation of a direct inguinal hernia though no hernia had ever been present. To express in a word Mr. Russell's theory, he maintains that "acquired hernia does not exist." There is much to be said for this theory; it would serve to explain many anomalies that we meet with and to clear up many obscurities in connexion with herniæ. The proof of the theory, if it can be proved, will apparently depend chiefly on the demonstration of the frequent existence of these peritoneal pouches apart from actual herniæ. This should not be difficult if the theory be true. Herniæ do, however, occasionally exist, as of the cæcum, which possess no sac, and therefore there must be exceptions to the explanation which Mr. Russell advances.

Annotations.

"Ne quid nimis."

ANNIVERSARY DINNER OF THE MEDICAL SOCIETY OF LONDON.

The Medical Society of London, under the chairmanship of Dr. F. de Havilland Hall, the President of the society, celebrated its 131st anniversary dinner at the Whitehall Rooms, Hôtel Métropole, on March 8th. The great banqueting hall was crowded, the exact number of guests and members present being 205. Amongst the company were the Presidents of the Royal College of Physicians of London, of the Clinical Society, of the Gynæcological Society, of the Harveian Society, of the Hunterian Society, of the Irish Medical Schools' and Graduates' Association, of the Obstetrical Society, and of the West London Medico-Chirurgical Society; Sir A. Rücker, Professor T. Clifford Allbutt, Professor Howard Marsh, Sir John Wolfe Barry, Mr. J. W. Comyns Carr, Dr. W. H. Allchin, Sir Alfred Cooper, Dr. J. K. Fowler, Mr. A. Pearce Gould, Mr. J. H. Morgan, Sir Henry F. Norbury, K.C.B., Sir H. Oakley, Sir G. S. Robertson, K.C.S.I., Mr. Mayo Robson, Mr. Edmund Owen, Sir Thomas Smith, Bart., the Mayor of St. Marylebone, Sir William Taylor, K.C.B., and Dr. S. West. The toast of the evening, that of "The Medical Society of London," was proposed by Professor Allbutt. The great size of the banqueting room somewhat marred the effect of Professor Allbutt's speech but to judge from the applause of those seated near the orator his opinions were received with great approbation. Professor Allbutt's remarks really amounted to an able denunciation of the present-day fashion of specialisation in the medical world. He contended that a stand should be made against the ever-widening division between medicine and surgery and he pointed out that the very name of the medical society implied the unity of the profession which he was so anxious to urge on the notice of his audience. The President of the Medical Society, in responding to this toast, elicited loud applause on his informing his hearers that the name of Lord Lister had been placed on the roll of honorary members of the society. Mr. Owen, in a characteristically witty speech, proposed the health of the guests. In the course of his remarks on Sir William Taylor, the Director-General of the Army Medical Department, he observed that he was a splendid recruiting officer because he was attracting to his department some of the best men from the hospitals. Sir John Wolfe Barry, who was the first to respond to this toast, remarked that although surgeons had but little choice of the materials on which they operated, nevertheless engineers were also limited in choice in regard to securing foundations for their structures. Sir William Taylor, who next spoke, made some amusing allusions to the temporary difficulties caused by the general reorganisation by which, he said, everyone at present seemed to be affected. After Mr. Comyns Carr had also replied to the toast of "The Guests," Dr. Allchin proposed "The President" and this having received a suitable acknowledgment brought the evening's proceedings to a close. The great success of the dinner was very generally acknowledged to be due to the organising talent of the registrar of the society, Mr. W. R. Hall.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

WE are glad to be able to report that the first part of the programme undertaken by that young and very vigorous body the Metropolitan Street Ambulance Association has been accomplished with encouraging results. Of the 118 gentlemen who have just been elected upon the London County Council 104 have given satisfactory replies to the question sent by the association to them during their candidature asking, "If elected to the London County Council, will you interest yourself in securing the establishment by the Council of an efficient street ambulance service for London?" Nor do these figures tell the whole story, for the cynical may say that they do not greatly regard election pledges. But, as a matter of interesting and important fact, many of the answers received from the 118 members of the new County Council show that the writers take as warm an interest in the question of an adequate ambulance service for London as does the medical profession itself. There is, therefore, every reason to hope that the London County Council will without delay take steps to ascertain what practical course can be adopted. A detailed scheme will be prepared by a subcommittee of the Metropolitan Street Ambulance Association for presentation to the Council at an early date and much will depend upon the character of this scheme. If it is simple, economical, and practical there is no reason to doubt that the London County Council will look upon it with favour and we do not see why immediate results should not follow. It is important to remember that a body like the London County Council will be greatly strengthened in any course it may decide to pursue if it feels that it can rely on the support of the whole medical profession of London in a question of this nature. Medical men can promote the movement by sending evidence showing the lack of proper ambulance accommodation in their neighbourhoods to Dr. Arthur W. James, 69, Gloucester-terrace, Hyde Park, W., who is acting as honorary secretary of the Metropolitan Street Ambulance Association, as well as by enrolling themselves as members of the association—a proceeding for which there is no charge. As a matter of fact, not much more evidence than the endorsement of the medical profession is required to show that the needs of London for ambulances of all sorts are almost unsupplied. The lack in the metropolis of adequate provision for dealing with street accidents is deplorable, while facilities for using such supply of ambulances as we have are entirely absent. Suppose a street accident to occur within ten minutes' walk from an ambulance station—which is supposing a great deal—how long would it be before the victim was in a stretcher? A policeman must be found. When found he must stay with the injured man while another constable, or some member of the public, goes for the ambulance. And when it arrives how long will it be before the patient is in the hospital? In New York the horse ambulance system originated in 1870 and proved so valuable that many other American cities quickly adopted the same methods. In Vienna the service was established in 1881 and in Paris in 1888, while in Liverpool the horse ambulance for street accidents was first tried in 1884 and ever since has proved to be invaluable. Horse ambulances summoned by telephone have long been looked on as an indispensable feature of hospital work in Birkenhead, Manchester, Newcastle, Huddersfield, Bolton, Burnley, Hull, Sheffield, Leeds, Wolverhampton, and Ipswich. Bearing in mind the loss of time occasioned in London by the use of the hand ambulance it is not surprising that from 8000 to 10,000 street casualties have to be removed each year in cabs or in other unsuitable conveyances.

CEREBRAL SYMPTOMS AFTER ABSORPTION OF DROPSY.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Jan. 15th M. Pierre Merklen and M. Jean Heitz called attention to the fact that the absorption of dropsy, whether cardiac, hepatic, or renal, may give rise to cerebral symptoms, such as coma, Cheyne-Stokes respiration, delirium, or convulsions. These may prove fatal, terminate in recovery, or cease with the return of the dropsy. This fact was observed by old writers but it appears to have passed out of notice. Graves has remarked that eclampsia sometimes is of favourable significance in regard to recovery from dropsy. Rilliet has observed that the convulsions of acute nephritis are frequently associated with diminution of the œdema. Bartels has several times seen uræmic symptoms occur when rapid absorption of renal dropsy was produced by diuretics or purgatives. Andral has described coma, from cerebral œdema, and asphyxia, from pulmonary œdema, as results of the rapid absorption of cardiac dropsy and as causes of rapid death. Eichhorst has recorded less severe consequences—somnolence, delirium, myosis, facial congestion, and deep and rapid respiration, like that of diabetic coma. The experience of M. Merklen and M. Heitz agrees with that of Eichhorst. They have observed five cases, in four of which there was cardiac disease and in the fifth renal cirrhosis. All these cases are connected by the link of renal insufficiency. The patients were aged and their kidneys were therefore probably acting insufficiently. In the cases described by M. Merklen and M. Heitz the ages varied between 56 and 71 years. Atheroma of the renal arteries was present or was suspected. The symptoms are due to defective excretion of the absorbed dropsical fluid which causes visceral œdema, especially pulmonary and cerebral. The existence of this "serous apoplexy" is not a mere hypothesis. Andral found in one case the lateral ventricles so distended that on incision fluid gushed out abundantly. Even in cases of coma recovery is possible and it often coincides with the return of the dropsy. The duration of the symptoms varies from some hours to some weeks. Treatment consists in promoting elimination by the kidneys and other organs. When the symptoms are acute and connected with insufficient diuresis bleeding may be necessary; it is indicated in eclampsia and coma. When the symptoms are less severe, such as delirium or torpor, repeated local blood-letting—wet cupping of the loins and the application of leeches to the mastoid processes—and drastic purgatives should be ordered. Fluids should be given in only very small quantities. The following is one of the cases related. A man, aged 65 years, was admitted to hospital in December, 1901. Three years previously his legs began to swell and a fortnight before admission ascites appeared. There were double pleural effusion, ascites, much œdema of the legs, and slight icterus. The urine did not contain albumin. Under treatment the œdema diminished. In April, 1902, the œdema extended to the abdominal wall and the effusions increased. The quantity of urine diminished to one litre in 24 hours and the kidneys did not excrete methylene blue administered to test their activity. From July to October paracentesis abdominis was performed thrice. On Oct. 29th the patient was somnolent and passing urine and fæces in the bed. M. Merklen and M. Heitz were surprised to find that the œdema of the legs had almost disappeared and that the ascites and pleural effusions were no longer perceptible. The liver and spleen were enlarged. On the 30th he was semi-comatose and there were general muscular rigidity, Kernig's sign, and dilated pupils. On the 31st there were deep jaundice and choluria and the coma was diminishing. With the improvement the anasarca and ascites returned and the quantity of urine increased to three litres in the 24 hours. He gradually regained his previous condition. On April 18th, 1903, he was readmitted. Until the 16th he had felt well and had gone about with his big abdomen and swollen legs. Then he suddenly became somnolent and simultaneously the swelling of the abdomen and limbs subsided. On admission he presented the symptoms found six months previously, but in a more severe form. On the 19th there were deep jaundice, vomiting, and melæna. On the 23rd he began to improve but the dropsy gradually returned. He died on May 31st. At the necropsy moderate ascites, chronic peritonitis, and atrophic cirrhosis of the liver were found. The kidneys were rather small and showed on microscopic examination chronic arteritis and subacute epithelial nephritis. There was slight left pleural effusion and the lungs were œdematous. The heart was a little dilated. There was marked effusion into the pia-arachnoid spaces.

THE WINTER'S WEATHER AT THE CONTINENTAL RESORTS.

THE following table gives a summary of the temperature and rainfall experienced at most of the principal health and pleasure resorts on the continent during the three months, December to February, of the past winter. It is permissible to speak of the winter as past in those southern latitudes, for whatever may be the case in our more northern clime spring in those favoured spots does undoubtedly commence with March. As would naturally be expected, the warmest place was Algiers, where the mean temperature was 56° F., or about equal to an average London temperature at the beginning of June. But as a drawback it will be observed that it was also the wettest. The resort with the lowest mean temperature was Florence but it was also one of the driest as regards the aggregate rainfall as well as one of the driest in the matter of days with rain. It should be said that a "day with rain" in the above table signifies a day when four-hundredths of an inch have fallen. After Algiers the places with the warmest mean temperature were Lisbon and Naples and these two cities had the advantage that their temperature was more equable than at any other spot. Lisbon's absolute maximum temperature was the lowest and its total rainfall was considerably less than that at the majority of the other stations. It had, however, with Biarritz, many more days with rain than most other places. Frost was recorded by the screened thermometer at Biarritz, Florence, Nice, and Rome. At Biarritz the thermometer descended to 32° or below on no less than 11 different nights, but at Florence the number was only six and at Nice three, while Rome had but one frost.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

Professor E. A. Minchin of the University of London delivered the first of a series of eight lectures on the sporozoa at University College, London, on Feb. 29th. During recent years the study of this important group of micro-organisms has received great attention in connexion with the etiology of such diseases as malaria, cancer, and certain tropical diseases of parasitic origin. The sporozoa, said Professor Minchin, constitute a group of protozoa widely distributed in nature and universally characterised by parasitic habits. They infest the internal organs and tissues of almost all classes of animals. There is, perhaps, no species of worm, mollusc, crustacean, insect, or vertebrate which is not liable to become the involuntary "host" of some kind of sporozoon parasite. Correlated with their wide distribution the sporozoa exhibit great diversity of anatomical characters and life-history. Yet the sporozoa as a group possess certain very characteristic features in common, peculiarities which are in direct relation with their habit of life as internal parasites. Their nutriment is always of a fluid nature—viz., the blood plasma or juices of their host, absorbed osmotically at the surface of the body of the parasite. None of the special organs for ingesting or digesting solid food, so frequent in other protozoa, are ever found in this group, while food vacuoles and contractile (excretory) vacuoles are always absent. The sporozoa are exceedingly fertile, an abundant progeny of several hundreds of motile spores (swarm spores) being formed within, and liberated from, the body of the parent. This occurs within the tissues of the host inhabited by the sporozoon. Thus the common earthworm harbours within its body a sporozoon (*monocystis agilis*) which infests the vesiculi seminales and lives (endoparasitically) within the sperm mother cells. Around the margin of these cells the spermatozoa of the earthworm develop while the parasite grows within the cell until, when it has attained full size, it is seen to be covered by a layer of spermatozoa. The growing parasite is pear-shaped and consists of a single nucleated protoplasmic body which soon issues forth from its spurious covering and leads a free life. This free parasitic stage is the "sporont" stage. Sporonts when fully grown conjugate in pairs or gametes. Each pair secretes a cyst wall within which the protoplasm and nuclei undergo segmentation into numerous small oval-shaped masses of nucleated protoplasm (zygotes). Each zygote eventually divides by repeated fission into eight smaller organisms within a single shell or covering; these are called sporozoites or falciform bodies. These zygotes undergo no further development in the body of their host the earthworm. When the latter, however, is devoured by birds the sporozoites are set free and pass out with the fæces of the latter as individual sporozoites to be again swallowed by the earthworm within the body of which the life cycle above detailed is repeated. Some sporozoa may invade the human body and produce disease at certain stages of their life-history passed within the body of man, a subject that will be fully expounded in the succeeding lectures. The second lecture delivered by Professor Minchin on March 7th discussed the life relations of two important classes of sporozoa—the coccidia and the gregarinæ. The coccidia were, he said, minute parasitic organisms which infested the intestinal canal of worms, crustaceans, and other arthropods. They were occasionally present in echinoderms but the higher vertebrates (those above the grade of amphibians and the tunicates) were free from these parasites. Abundant spore formation by fission was a characteristic feature of these organisms, the number of spores being often so great as to produce the death of the host. This phenomenon was termed death by auto-intoxication. The spores might enter and infect a suitable host in a variety of ways—e g , by being eaten with the food (casual infection) or by being inoculated into the host by a mosquito or other insect which served as an intermediate host (infection by inoculation). The *gregarinæ* were larger and more highly developed organisms than the coccidia, but their distribution as parasites included the same classes of animals as those infested by the coccidia. In a few rare cases of skin disease occurring in South America investigation has shown that the virus is a coccidium which is communicated from one person to another by contact. The sporozoa were divided into two great classes—viz , the telosporidia in which spore formation occurred only when the animal reached the adult condition (gregarinæ, coccidia, and hæmosporidia) and the neosporidia in which spore formation took place in the early stage of the life-cycle of the animal. The former class contained certain sporozoa which were pathogenic to man, including the deadly malarial parasite and others which were the probable agencies in the production of certain tropical diseases.

THE PHYSICS OF THE DAMP BED.

THE question is very commonly asked as to why it is dangerous to sleep in a damp bed. Some persons even deny that there is any risk, confidently recounting perhaps in support of their view an experience in which no harm had ensued to them, even although the mattress had been accidentally kept wet through the night by the leaking of a hot water bottle. A consideration of the physical condition of the damp bed easily accounts for its danger to health and it does not follow that while there is risk when the coverlet is damp the risk is quite the same when the mattress is superficially wet. To begin with, damp air is not only a conductor of heat, so that the warmth of the body when surrounded by it easily escapes, but it also communicates a dampness to the coverlet which destroys its non conductivity. The danger of sleeping in a damp bed, however, lies not so much in the dampness of the air as in the dampness of the clothes. The vital principle of the bed coverlet, as it is with all clothing, is that it should be as far as possible non-conducting—i.e., having the property of preventing the escape of the natural heat of the body. When clothing is damp it loses to a large extent this property and so the body loses its natural warmth, experiences a chill, and a serious illness may ensue. It is therefore conceivable that no harm would result if merely the mattress of a bed were wet so long as the upper coverings, the sheet, the blanket, and the coverlet, were perfectly dry, effectually preventing, that is, the escape of the body heat. A chill does not arise from the cold of dampness (cold and damp are not interchangeable terms) but from the facility with which damp air and clothes allow *the natural warmth to escape*. *Damp clothes, in short,* are good conductors of heat while dry clothes are insulators, and the degree at which the heat of the body is maintained in bed is a measure of the insulating value of its coverings. The risk of sleeping in damp clothes would be the same as *if copper or tin foil were used for the purpose.* It follows that the only practical and trustworthy test for a damp bed would be to place, say, a hot water bottle in it and to note how rapidly the temperature of the water falls. According to the principles just laid down the difference would be very perceptible in the case of a damp and in that of a dry or well-aired bed. The so-called damp detectors, which depend upon the stretching of a fibre or hair in dry air and its shrinking in moist air, give, in reality, no useful indication, neither does a watch glass showing the deposition of moisture

A SANATORIUM IN THE BALANCE.

IN dealing with the subject of tuberculosis we have from time to time pointed out that unless the advocates of sanatoriums were less optimistic in their prophecies as to the benefit which is to be anticipated from these admirable institutions a reaction based upon disappointment was inevitable. Unfortunately for the true interests of the consumptives this reaction has already set in and those who have preached in and out of season that solely by sanatoriums consumption could be "stamped out" are alone to blame for this regrettable result. Sanatoriums have to some extent been promoted and built upon the implied if not specific understanding that in allowing three months' residence for each patient cure might be effected and now that the necessary interval has elapsed and the prophecy has been unfulfilled the chickens of exaggeration are returning to their roost. Apparently the Heswall Sanatorium which was recently erected by the board of guardians of the city of Liverpool on a site overlooking the waters of the Dee has not passed altogether unscathed through the criticisms levelled against its first annual report. The results, in so far as they can be gauged from the figures furnished by our Liverpool correspondent last week, do not astonish us as we have never been led away by the "stamping out" will-o'-the-wisp. But apparently the Liverpool guardians, as well as one of the medical officers of the institution, thought otherwise. It seems that 56 patients were admitted during the year and of these seven died. This fact conveys little to us unless we know the precise stage of the disease on admission of the patients and the duration of stay in each case. If the cases were advanced or, perchance, moribund on admission the figures convey no information of any value and until we receive more detailed data we shall withhold comment. At the date of the report there were 21 patients in the sanatorium; 18 of these were reported to be improving and in three the disease was arrested. The chairman apparently regarded the report as disappointing but it was determined in order to give the institution a fair trial to keep it going for another 12 months and to endeavour to secure more cases in the primary stage of the disease. If early cases are secured we have little doubt that next year's report will be of a much more encouraging character. But it is nevertheless much to be regretted that apparently in consequence of the admission of unsuitable cases the public will receive a shock in connexion with the institution and a shock which may, we fear, prevent other boards of guardians from following the example of Liverpool. But whatever may be the facts with regard to the Heswall Sanatorium it cannot be doubted that professional opinion in this country is undergoing some change with respect to the functions of a sanatorium. With the over-statements of the enthusiasts, of those who had but slight knowledge of epidemiological problems and of the effect upon other diseases of hospital isolation, a "stamping-out" wave passed over the country. Now, when it is shown by experience that a stay of three months is insufficient to bring about a cure there is in no small measure a change of front and an effort is being made to erect sanatoriums for the purposes of education alone. This idea is in its turn also excellent but the application of it should, it seems to us, be approached cautiously, intelligently, and economically. But in the meantime the public will perhaps ask whether they are likely to find stability even in this educational aspect of sanatoriums and we should not be altogether surprised if they asked for some more authoritative opinion than they at present possess before they agree to sanction indefinite expenditure in this direction. Would it not be well, looking at the issues at stake, if a Royal Commission or a departmental committee were appointed thoroughly to examine the question. It is, of course, easy to refer to the practice of Germany and, disregarding the fact that the circumstances of the working classes in the two countries are essentially different, to follow the German example. But before doing this, it would be well to ascertain what influence the elaborate system of workmen's insurances in Germany plays in the battle against consumption. Moreover, it would be wise to learn in what manner sanatoriums could be most economically and expediously provided and if these institutions are to be used for educational purposes alone what is the length of stay proposed in each case and what are the benefits likely to accrue therefrom. Could, too, those benefits be procured in a less costly fashion by other means? There is probably no doubt in the mind of anyone at all conversant with the facts that sanatoriums, if properly administered, are excellent institutions, although tuberculosis will never be "stamped out" by them alone and in some cases equally good results may be attained outside the walls of such places. What it appears to us is wanted before the greatest use can be made of sanatoriums in a curative sense is some better machinery by which early cases of consumption may be recognised and brought under control and the Heswall incident is, perhaps, an apt illustration of that need.

THE AIR OF UNDERGROUND RAILWAYS IN ITS RELATION TO DISEASE.

In matters appertaining to the public health it is easy to drift into hysteria and one result of such a course is to divorce level-headed public opinion, which after all is the real controlling legislative force, from sympathy with preventive medicine. But at the present time when in London at certain periods of the day men and women of all classes, who for the most part have spent or are about to spend their day in work, are huddled together in railway carriages in a fashion somewhat suggestive of cattle on the way to the shambles, any ray of light tending to show to what extent the air of underground railways and carriages becomes polluted is worthy of consideration. The latest contribution to this subject is a report by Dr. W. Scott Tebb, the public analyst of the borough of Southwark, on the condition of the air in the City and Suburban Railway, and although the air of the tube is not fairly comparable with that of the Metropolitan Railway it is not difficult to draw certain inferences from the records of the tube. The results of Dr. Tebb's investigations are in no sense contrary to expectation but notwithstanding this they are instructive and interesting. The experiments were only quite recently performed and hence they may be taken as typical of winter conditions. Each experiment was carried out in duplicate and in presence of a control in the open air and in addition to the estimation of carbonic acid and bacteria records were taken as to the temperature, humidity, and movements of the air. The average temperature on the platform was 61° F. and that of the street at the same time 49° F.; the humidity of the air on the platform was greater than that in the street. The velocity of the air on the platform varied from one mile to eight miles an hour according to the position of the moving trains. As regards micro-organisms in the street, railway platform, and railway carriage the method adopted was to expose agar plates in duplicate for half an hour, to incubate the plates at 37° C. for 22 hours, and then to count the colonies. The results are held to afford a fairly trustworthy comparison between the air of the three sources under examination and the following table based upon averages furnishes a general idea of the conditions obtaining at the period of the experiments:—

Air of—	Number of experiments.	Micro-organisms.
Street	52	459
Railway platform ...	46	114
Carriage	8	218

But the examinations made at different periods of the day and night illustrate how markedly the number of organisms in the air is governed by agencies which promote both the formation and the movement of dust and in what manner the relative quietude of the early morning both in the street and in the tube and of the afternoon in the tube influences the situation. The following table explains itself:—

Hours.	Number of micro-organisms.	
	Street.	Tube.
2 A.M. to 6 A.M.	52	54
6 A.M. to 10 A.M.	412	249
10 A.M. to 2 P.M.	455	102
2 P.M. to 6 P.M.	427	54
6 P.M. to 10 P.M.	574	111

Turning to the carbonic acid, a very similar state of affairs was found. Outside the railway stations in Southwark the carbonic acid averaged 3·8 parts per 10,000, the amounts ranging from 3·1 between 2 A.M. and 6 A.M. to 4·3 between 2 P.M. and 6 P.M. Inside the stations the amount varied from 3·5 to 9·3 the amount increasing progressively from morning to night. As a result of his investigations the author suggests that means should be adopted to reduce the carbonic acid in the tube to 6 parts per 10,000 the usual limit of permissible impurity, and he thinks that some more efficient system of ventilation should be adopted in the carriages. No one will, we imagine, wish to quarrel with these recommendations, although it may be somewhat difficult to realise them in practice. With regard to these investigations of Dr. Tebb it has, of course, to be borne in mind that carbonic acid as such is not detrimental to health even in amounts considerably in excess of the 6 parts per 10,000 referred to above. But the carbonic acid is taken as a convenient and easily determined index of the amount of organic matter in the air. Hence the risks are greatest when an excess of carbonic acid is associated with the presence of animals or human beings capable of giving rise to this indefinite organic poison of which the carbonic acid is accepted as an index. Although Dr. Tebb's investigations and conclusions relate exclusively to the tube, they suggest certain reflections as regards the carriages on the Metropolitan Railway. For instance, it would be difficult to imagine circumstances more likely to give rise to an excess of organic matter and carbonic acid than the presence of 16 or 17 persons in a metropolitan railway carriage, more particularly when both windows and the ventilators are also closed, or when a broad-shouldered navvy or other corpulent person is blocking the window aperture. It would be of interest to estimate the carbonic acid in these circumstances between 6 and 7 P.M. in one of the Ealing trains and we might rest assured that the carbon dioxide would at least not under-estimate the amount of organic matter present. As regards the number of organisms, plates placed on the luggage rack might afford some instructive lessons; but it has to be remembered that unless there is actually coughing or loud speaking droplets are unlikely to be given off. That the overcrowding which takes place increases the risk of contracting specific disease is a self-evident proposition which is not worth discussion. If a similar overcrowding took place on the public carriages in the streets above ground the metropolitan police would soon put an end to it; the ticket collectors below ground are relatively useless except for the protection of the company. For the public their concern is small. Why not, therefore, convert the Metropolitan Railway into a "street," let the metropolitan police have access thereto, and let the cost be borne by the company? Or are we to wait until a serious railway accident by damaging or destroying the lives of those in an overcrowded train results in such heavy damages against the company that in its own monetary interest it will take the necessary steps?

THE MANAGEMENT OF THE ROYAL BERKSHIRE HOSPITAL.

THE Royal Berkshire Hospital held a special court of governors on March 1st when various proposed alterations in the rules of the institution as affecting the honorary staff and other officials of the hospital were considered. Discussion waxed rather hot and certain proposals adopted by the board of management for discussion at the special court were not carried. A committee had been appointed to inquire into the duties of the resident medical officers and had reported as follows:—

> This committee are of opinion that: 1. The resident medical staff should remain as at present constituted, but that a senior resident

> Rogers, James R. Andrew Clark.

Mr. Walters moved that a clause should be added specifically stating that the new official should not interfere with the honorary acting medical staff or with the patients under their care and this clause was agreed to and incorporated in the report. After some discussion the report was finally referred to the annual court of 1905. As the matter is in abeyance for a year or so there is plenty of time for the governors of the hospital to consider what they are doing. It seems to us that if the new official is not to be a medical man to give him jurisdiction over the resident medical officers is courting disaster. A tactful lay official might not seek to interfere with the treatment of a house surgeon or a house physician, but all persons are not tactful. Moreover, we do not think it desirable that a layman should act as registrar to a hospital. For a registrar to be of any use in a hospital he must be a medical man. With regard to the point of setting an official over the resident medical staff there is much to be said on both sides. Some of the London hospitals have a permanent resident officer who is set over the house physicians and surgeons and some have not. But wherever such an official does exist he is always a medical man. Therefore we think that the governors will be well advised to insist that if the proposed official is to exercise jurisdiction over the resident medical officers he must be a medical man. Among other proposals which came before the court was one to the effect that no one should be eligible for the post of surgeon or physician to the hospital who held a dispensary, Poor-law, or club appointment; this proposal was not carried.

FOOD IN WARM CLIMATES.

IN a pamphlet published at Santa Cruz de las Palmas Dr. Sanchez Reyes of the Spanish Army Medical Service discusses the alimentary merits of *el gofio* as a food capable of sustaining human life and strength in warm climates. *El gofio* is a generic name for various products which are manufactured from different flours, including those obtained from wheat, maize, barley, white lupine, rye, chick-peas, and beans. The descendants of the gigantic Guanches are still a herculean race and yet they subsist upon this farinaceous food almost exclusively, their only extras being milk and a little coffee. Among the wealthy a few indulge occasionally in broth but meat cannot be said to be a staple ingredient in their diet. Of course, the climate of the *μακάρων νῆσοι*, or Fortunate Islands, is not one that calls for a highly nitrogenous diet, still there are many places with as high, or even a higher, temperature where the inhabitants think it necessary to consume animal food habitually. More especially is this true with regard to certain colonies which have been peopled by emigration from inclement regions. It seems certain that a diet in which meat forms the staple ingredient cannot be suitable in such cases but as years go by the *genius loci* will no doubt assert his power by gradually introducing a more vegetable regimen. Dr. Sanchez Reyes, after a somewhat elaborate examination of the chemical and physiological values of the various flours found in *el gofio*, comes to the conclusion that, associated with milk and eggs, the compound is amply sufficient for nourishment, especially in warm climates. He recommends it strongly as a ration for soldiers and in support of his contention claims the advocacy of Galen as well as the dietetic customs of the invincible Roman armies. Dr. Sanchez Reyes's pamphlet is decidedly interesting. As a writer in a late number of the *Revue des Deux-Mondes* observes: "The determination of the sources of muscular energy is ripe for discussion; it is one of the problems engaging contemporary science."

A CLASSIFICATION OF THE INSANITIES AS A BASIS FOR THE THEORY OF CRIMINAL RESPONSIBILITY.

IN a paper which is published in the *Edinburgh Medical Journal* for January Sir John Batty Tuke and Mr. Charles Howden, barrister-at-law, deal with the question of criminal responsibility in its relation to mental disorder and furnish a scheme of classification of the insanities as a basis for the further discussion of the question of responsibility in detail and with reference to each individual group of insanity. Although in theory the provinces of law and medicine are distinct great confusion between them has arisen in practice. This state of matters is due partly to the difficulties inherent in the subjects but in part also it is due to the persistence of traditional metaphysical views of insanity and to the imperfect condition of our knowledge of mental disease. The traditional views remained practically unchanged in Europe throughout the Middle Ages and up to the beginning of the nineteenth century. With few exceptions the prevalent views of insanity were "scholastic in character and indicated no real grasp of its nature, names and stock examples were repeated from one book to another," and the treatment of the insane was as marked by ignorance and superstition as its study and observation. The scientific, humane, and rational era in the treatment of insanity followed the teachings of Pinel in the second and third decades of the nineteenth century, but the knowledge of alienists in the early half of the century did not enable them to speak with sufficient confidence as to individual cases of responsibility. Most physicians were agreed that insanity arose from morbid cerebral and bodily conditions but little was known for certain as to the constancy and character of those conditions. The prevailing psychological classification into symptomatic groups of insanity—mania, melancholia, and dementia—did much to retard the advance of knowledge and scientific investigation. "Their common characteristics were so loose and superficial that to say a case belonged to any one of them gave no further information than could be derived from superficial observation of the case itself." The gradual recognition of distinct varieties of insanity and the perfecting of our system of classification have enabled recent writers to mark out more satisfactorily the existing varieties of insanity on a combined basis of evolution of symptoms, etiology, prognosis, and pathology. Medical men have also come to recognise that organic and grave lesions of the brain may exist without mental disorder sufficient to constitute insanity, as in cases of epilepsy, alcoholism, and lead poisoning, and that in other cases of similar nature grave mental disorder may exist. Sir John Batty Tuke and Mr. Howden propound a scheme or list of the groups of insanity to be considered *seriatim* in discussing the question of responsibility in future papers. The list is given below and includes the following varieties: idiopathic or vesanic mania and melancholia; general paralysis of the insane; insanity of cerebral traumatism; insanity associated with neuroses such as epilepsy, hystero-epilepsy, and hypochondriasis; insanity of cerebral syphilis, meningitis, and sunstroke; dementia præcox, puerperal insanity, climacteric insanity, and senile insanity; paranoia; and insanity from cerebral defect such as imbecility and idiocy.

"N" RAYS IN PATHOLOGICAL CONDITIONS.

IN THE LANCET of March 5th, p. 685, Mr. A. A. Campbell Swinton, who is well known in connexion with Roentgen ray work, took occasion to call in question the views as to the occurrence of "n" rays which M. Blondlot and others have published. The criticism is welcome since it is quite possible that the enthusiasm of a discoverer has led M. Blondlot to make some erroneous deductions from the results of his experiments, but there is a steadily increasing mass of evidence in favour of the essential accuracy of the view that muscle and nerve can produce characteristic effects upon a sensitive screen in the way described in an annotation some weeks ago. A further contribution to the subject has just been made in a note by M. Gilbert Ballet, presented by M. d'Arsonval to the Académie des Sciences and entitled "De l'Émission des Rayons N dans quelques Cas Pathologiques." Having satisfied himself of the fact that the "n" rays are emitted by living muscle, M. Ballet investigated the influence exerted upon a screen, coated with calcium sulphide and fixed at the end of a tube of lead about five centimetres long, by the tissues of a number of persons suffering from various diseases involving the muscular system. In a case of primary myopathy with complete atrophy of the deltoid and partial atrophy of the muscles of the forearm the diminution of the effect produced upon the luminosity of the screen when placed near the affected muscles was directly proportional to the degree of atrophy. Cases of wasting due to toxic polyneuritis, lead palsy, and neuritis of the facial nerve, together with four cases of infantile paralysis, yielded similar results. In three cases of hemiplegia of cerebral origin in which there was contracture of the muscles these were found to emit, as tested by the screen, a larger number of the "n" rays than the corresponding healthy muscles and the same thing was observed in a patient afflicted with spastic paraplegia. The data furnished by instances of hysterical paralysis are noteworthy: in one case of monoplegia and one of hemiplegia an increased production of the "n" rays was observed. As to the significance of this last fact M. Ballet desires at present to offer no opinion; it may, however, contain the germ of important developments in regard to the nature of what are distinguished as "functional" palsies.

DANGERS OF THE TRENDELENBURG POSITION.

THE Trendelenburg position, in which the pelvis is raised, is now very extensively employed for operations on the abdomen, especially when the surgeon has to deal with the pelvis. The advantages of the position are great, for the raising of the pelvis allows the action of gravity to withdraw the intestines from the lower part of the abdominal cavity, so that the pelvic viscera become much more readily accessible. Dr. F. Jayle, however, has recently pointed out in the *Presse Médicale* that this position is not free from danger, especially if the inclination of the body is over 45°. So high a degree of inclination is not common in this country but in France it is more frequently employed. The chief dangers attributed to the Trendelenburg position are the great strain thrown on the heart and acute pulmonary congestion. The raising of the pelvis leads to a flow of blood towards the upper part of the body and thus the right heart is liable to be overfilled and a disturbance of the pulmonary circulation results, with the production of pulmonary congestion. In one case Dr. Jayle had to postpone the operation because severe dyspnœa appeared whenever the patient was placed in the Trendelenburg position. Further, if the abdominal wound is closed while the body is still inclined there is a risk of shutting up a certain amount of air in the abdominal cavity. This air may be only slowly absorbed and some is liable to escape between the layers of the anterior abdominal wall. Dr. Jayle has seen extensive surgical emphysema result from this cause and give rise to a good deal of pain. In order to avoid this emphysema he suggests that the patient should always be placed in a horizontal position before the wound is completely closed. Still another danger is pointed out. Often the patient is kept in the inclined position merely by the bent legs passing over the edge of the table; this pressure of the table is said to have led in some cases to partial paralysis of the legs. All these possible dangers should be borne in mind in employing the Trendelenburg position but its advantages far outweigh these dangers which a little care and attention to detail will do much to obviate.

RESECTION OF THE CERVICAL SYMPATHETIC GANGLION FOR GLAUCOMA.

SINCE the publication of the results obtained by Professor Jonnesco of Budapest in the treatment of glaucoma by resection of the cervical sympathetic ganglion, an account of which was given in THE LANCET[1] some years ago, much attention has been given to the prognosis and results of this form of treatment In *American Medicine* of Jan. 20th Professor William H. Wilder of Rush Medical College gives an account of seven cases of sympathectomy for glaucoma personally investigated and discusses critically the results of all cases of glaucoma treated by resection of the sympathetic ganglion in the United States of America of which he could procure records. The results obtained by Professor Wilder himself as regards recovery do not appear to be so favourable as in the series of cases of sympathectomy published by Professor Jonnesco, but so far as they go they seem to justify this method of treatment. The following is a summary of the clinical features and the results obtained in the seven cases referred to. Case 1. The patient was a man, aged 40 years, with chronic inflammatory glaucoma of the right eye which resulted in gradual and progressive loss of vision terminating in blindness. He was operated on in May, 1901, and the right superior cervical ganglion was removed. Contraction of the pupil immediately followed and a few hours later the tension of the eyeball was lowered. Vision improved moderately in both eyes and the tension remained low, the degree of recovery being partial though permanent. Case 2 The patient, a man, aged 62 years, had chronic inflammatory glaucoma of both eyes Right sympathectomy was performed and marked improvement of sight followed. This improvement, however, became masked by the subsequent development of cataract in both eyes. Case 3 The patient was a man, aged 46 years, with simple (non-inflammatory) glaucoma of both eyes. Sympathectomy was performed on the left side but without benefit. Case 4. The patient, a man, aged 75 years, had simple glaucoma of the right eye and advanced glaucoma of the left eye. Right sympathectomy was performed with marked benefit as regards improvement of vision and the alleviation of symptoms. Case 5 The patient was a man, aged 76 years, with simple glaucoma of the left eye. Sympathectomy was performed and the further progress of the disease was arrested but recovery of sight did not take place. Case 6. The patient was a woman, aged 78 years, with the same affection as in the previous case, but improvement followed upon resection of the left cervical sympathetic ganglion. Case 7 The patient was a man, aged 57 years, with simple glaucoma, more marked in the right eye than the left. Sympathectomy was performed but without benefit. The general results were improvement varying from moderate to marked degree in four cases and no improvement in three cases. The excised ganglia in four cases were hardened in formalin and suitably stained to show pathological changes. In all the specimens, says Professor Wilder, there was increased pigmentation of the ganglion cells, and in two cases "mast cells" were seen. One case showed vacuolation of the nerve cells and eccentric displacement of the nucleus, but it was impossible, says Professor Wilder, to say as regards pigmentation how far the changes were normal (senile) or abnormal.

---

[1] THE LANCET, Sept. 30th, 1899, p. 899.

THE CHELSEA CLINICAL SOCIETY.

"Internal Secretion" in Disease and in Treatment was the subject of the annual clinical debate of the Chelsea Clinical Society commenced at the Chelsea Dispensary, Manor-street, King's-road, London, S.W., on March 8th. Sir Lauder Brunton, who opened the discussion, contributed a well-balanced general view of the subject and was followed by Sir Victor Horsley who dealt with the thyroid gland. He pointed out that at the present time the general idea of the internal secretion of that gland being affected by disease was simply that it came to an end, whereas, as Sir Victor Horsley proceeded to show, the gland in the process of becoming diseased poured into the circulation in addition to its normal secretion some substances of a poisonous nature. Dr. H. D. Rolleston raised the question whether the want of success in the treatment of exophthalmic goitre and acromegaly might possibly depend on the fact that two or more glands instead of one only were in each case in an abnormal condition. Dr. A. E. Wright ended the first night of this interesting debate by discussing the problems of immunity. In our next issue we shall present our readers with a report of the proceedings.

THE HEALTH OF THE KING.

His Majesty the King has now recovered from a sharp catarrhal attack. The cold, commencing as is usual in these insidious cases with irritation in the throat and mouth, was aggravated by the exertion of his visit to Cambridge where he necessarily was submitted to many changes of temperature in his conscientious inspection of the new buildings of the University. As a result on his return from Cambridge there were some fever and bronchial irritation. His Majesty was kept in rooms of a uniform temperature and the slight pulmonary symptoms soon subsided, the patient answering quickly to remedies. His Majesty's public movements have since shown that his restoration was considered complete by Sir Francis Laking who has been in attendance.

The annual meeting of the general council of King Edward's Hospital Fund for London was held on Tuesday last at Marlborough House, H R H. the Prince of Wales being in the chair. In moving the adoption of the report the Prince of Wales read a letter which he had received from a personal friend placing securities at the disposal of the Fund bringing in an income of nearly £4668 per annum if in the course of the year an increase of income from funded property amounting to £9332 in addition should be received. The figures are determined by the fact that the income of the Fund from permanent sources is £14,000 short of £50,000, this being the figure to which the generous donor wishes to raise it by contributing one-third of the deficiency. The report, which was adopted, presented many interesting features upon which we shall comment next week.

The medical officer of health of Cape Colony reports that for the week ending Feb. 13th no case of plague in human beings occurred throughout the Colony. Plague-infected rodents were found at Port Elizabeth, East London, and Queenstown, but of 175 rats examined in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on March 4th states that for the week ending March 3rd there were six cases of plague and five deaths from the disease.

The King has sanctioned the following promotions in the Order of the Hospital of St. John of Jerusalem in England: Knights of Grace: Colonel (Honorary Surgeon-General) William Daniel Campbell Williams, C.B. (from Honorary Associate), and Dr George Thomson (from Honorary Assocate). Dr. William Allan Jamieson has been appointed Esquire of the Order.

The Ecclesiastical Commissioners have signified their willingness to contribute a sum of £2500 towards the King's College Hospital Removal Fund. The Commissioners expect that the poorer residents upon their property in South London will benefit by the proximity of the hospital when removed.

At the meeting of the Neurological Society of the United Kingdom, to be held at 11, Chandos-street, London, W., on Thursday next, March 17th, at 8 30 p.m., Dr. Alfred W. Campbell will read a paper on Histological Studies in Cerebral Localisation.

The King has appointed Sir Thomas R. Fraser, M.D. Edin., LL.D., to be one of His Majesty's honorary physicians in Scotland.

A meeting of the Epidemiological Society will take place at 11, Chandos-street, Cavendish-square, W., on Friday, March 18th, at 8.30 P.M., when a paper on the Epidemiology of Enteric Fever and Cholera in Hamburg will be read by Dr. Reincke, medical officer of health of the city of Hamburg.

THE POLLUTION OF TIDAL ESTUARIES.

For some years past, and more particularly since the issue in 1896 of the Local Government Board's report upon the conditions under which oysters and other molluscs are cultivated, an increasing amount of attention has been paid to the question of the pollution of our estuaries. Although there is room for legal quibbling and academic discussion upon the point, the fact remains that in practice crude sewage can, for the most part, be discharged into tidal waters with impunity, as the Rivers Pollution Acts do not apply to tidal waters unless such waters are declared by the Local Government Board, after inquiry, to be "streams" within the meaning of these Acts. In only a very few instances have inquiries of this nature been made by the Local Government Board and in fewer still have the estuaries been declared "streams."

There is, however, another method of preventing the discharge of crude sewage into estuaries, as the corporation of Chichester recently learnt to its cost when action for an injunction to prevent it from fouling the harbour was taken successfully by Lord Gifford. As further evidence of the growing interest which is being taken in this question reference may be made to the recent very important report of the Royal Commission on Sewage Disposal which dealt exclusively with tidal waters and which we noticed at length in The Lancet of Jan. 16th, p. 167, as also to the fact that three other reports, one of which is an official one, have also been recently issued.

We propose here to give a general outline of the nature and conclusions of these three reports, commencing with those which were first issued. The author of the first two is Mr. A. G. R. Foulerton, county medical officer of health to the East Sussex county council. One of them deals with the pollution of the tidal portion of the river Ouse in Sussex and with the relation of the enteric fever in the vicinity to such pollution, and the other is a report to the local fisheries committee of the Sussex Sea Fisheries District and relates to the pollution of the Shoreham and Chichester harbours and of the tidal Adur. As regards the Ouse, this river enters the sea at Newhaven and it is heavily polluted by the crude sewage of Lewes as well as, in a minor degree, by the sewage of other places. The incidence of enteric fever on the population of the town of Newhaven is exceptionally high and Mr. Foulerton, after a thorough consideration of the circumstances and conditions, topographically, chemically, and bacteriologically, as well as of the age distribution of the population, arrives at the conclusion that the endemicity of enteric fever in Newhaven is most probably ascribable to the polluted foreshore of the river Ouse as it traverses the borough. Such influence is, he thinks, exerted mainly through the agency of flies which, after settling upon the polluted foreshore at low water, turn their attention to milk and other foodstuffs of the Newhaven population. He thinks, too, that mussels taken from the same foreshore have, although in a minor degree, an influence in the same direction. His chief proposal is to ask that the Ouse should be declared a "stream" and that those who now contribute crude sewage to its waters should be made to purify it.

Mr. Foulerton's *report upon the pollution of tidal fishing waters* is a very thorough piece of work. He has carefully surveyed the harbours and estuaries in question, has taken samples of water for chemical and bacteriological examination, and has estimated, so far as the very complicated considerations involved will allow, the effect of the pollution both upon the fish and the molluscs to be found therein and upon the risk to the public of consuming such fish. We have not space to follow Mr. Foulerton in detail but we can say that he has approached the subject in a thoroughly scientific spirit and that he has held in view not only the risk to public health which may obtain from the consumption of shell-fish taken from certain points liable to pollution but he has also kept before himself the fact that a large industry is at stake and that the livelihoods of many persons are in the balance. He has, in a word, had an eye to the relative proportions of the subject. Probably much of the area covered by Mr. Foulerton's investigations may before long come beneath the jurisdiction of one of the Rivers Boards, the formation of which has been so strongly urged in both the third and fourth reports of the Royal Commission on Sewage Disposal, and the Rivers Board which secures the well-balanced advice of Mr. Foulerton will be in safe hands.

The third report to which we have referred is a voluminous and comprehensive report made to the Local Government Board of Ireland by Dr. T. J. Browne, one of its medical inspectors, and Professor E. J. McWeeney, bacteriologist to the same department. This joint report represents the results of a comprehensive inquiry into the conditions of the shell-fish layings, &c., on the Irish coast as regards their liability to contamination by sewage. To Dr. Browne was intrusted the topographical survey which was carried out much upon the same lines as those set forth in the well-known and exhaustive report made by Dr. H. T. Bulstrode to the Local Government Board of England in 1896, while to Professor McWeeney was deputed the task of examining the specimens of molluscs, water, and mud which were forwarded to him by Dr. Browne. Each observer worked independently of the other and it was only at the termination of the investigation that the results were compared. The joint report is prefaced by an able summary from the pens of Sir H. A. Robinson and Mr. T. J. Stafford of the Local Government Board of Ireland, in which they point out that the report is not to be regarded as other than a superficial examination of the foreshores in so far as they seem to be affected by sewage contamination, and, they add, with a caution bred of knowledge, that "to enable us to distinguish conclusively the layings which may be regarded as reasonably safe from those which are not far more prolonged investigations by both Dr. Browne and Professor McWeeney would be required than time and the pressure of other work has so far permitted." There is no doubt in our view that this is an eminently sound attitude. To examine each estuary thoroughly would in itself require repeated visits and a consideration of all the circumstances, perhaps, throughout a whole cycle of tides. But, this notwithstanding, both Dr. Browne and Professor McWeeney have performed in a short space of time an admirable piece of work which will furnish a sound foundation upon which they and other observers may work in future. Dr. Browne's portion of the report is illustrated by numerous maps, showing by different colours and signs the areas devoted to shell-fish (oysters, mussels, cockles, and periwinkles) culture, growth, and storage, as well as the positions of the sewer and drain outfalls. As a result of his survey Dr. Browne has made a sort of provisional classification of the beds, layings, &c., into (1) those which are apparently *free* from pollution; (2) those the purity of which must be regarded as *doubtful*; and (3) those which appear undoubtedly to be *contaminated*. This classification will prove useful for the application, cautiously, of any administrative measures which may be enacted as a consequence of the recommendations of the Royal Commission on Sewage Disposal. In this connexion it is important to note that Dr. Browne's report shows that there is a very material interchange of shell-fish between England and Ireland, and that, hence, any administrative measures to be of the greatest utility must apply to all parts of the British Isles.

Professor McWeeney in his preliminary remarks sets out fully and in interesting fashion the precise steps which he took to ascertain the presence or absence of organisms which he regards as being indicative of pollution by sewage, and we read with interest that although he attaches very considerable importance to the presence of typical bacillus coli communis he attaches but little value to the presence of the bacillus *enteritidis sporogenes*. He says, in fact, "I very much doubt the significance of the presence of B. enteritidis." This is an instructive and interesting fact having regard to the very great importance which Dr. E. Klein apparently attributes to the presence of this organism. Professor McWeeney inclines to the view that contamination may be gauged not by the mere presence of the bacillus coli but by the degree of concentration of that bacillus and his standard has apparently been the presence or absence of what he regards as typical bacillus coli in one cubic centimetre of oyster fluid or of water. But with characteristic honesty and frankness and with true scientific insight he proceeds to question his standard by stating that before the problem as to whether that standard is a fair one or not can be decided it is necessary to ascertain (*a*) whether oysters, &c., *which do not contain* the colon bacillus in one cubic centimetre can be shown to contain it in their entire *organism*; (*b*) whether the colon bacillus is ever demonstrable in small quantities (one, ten, or 100 cubic centimetres) of sea water taken far from the shore and therefore absolutely free from all possibility of contamination with sewage; and (*c*) whether there exist in the sea water of oyster beds sources of bacillus coli (*sensu stricto*) other than sewage. Here Professor McWeeney refers "to the possibility that the intestinal contents of the sea-fowl and fish may contain that organism and under certain circumstances liberate it into the water in quantities large enough to perceptibly affect its bacteriological character." These are the very points the importance of the solution of which was urged upon the Royal Commission on Sewage Disposal by Dr. Bulstrode and Dr. J. C. Thresh, and apparently the researches of Dr. A. C. Houston have enabled him to answer (*a*) in the affirmative. We must, however, await the issue of his full report before we are in a position to speak positively with regard to (*b*) and (*c*). But with reference to (*c*) we may call attention to a communication in THE LANCET of March 5th, p. 648, by Dr. J. W. H. Eyre on the Distribution of Bacillus Coli in Nature, in which he states that he has for some years past examined from time to time for bacillus coli the fæces obtained from various animals and, omitting land animals, it may be pointed out that Dr. Eyre found what he regards as typical bacilli coli in the intestinal contents of the duck, the pigeon, and the sparrow. He has also examined freshly killed sea birds, procured for him through the kindness of Dr. Bulstrode, and has isolated therefrom specimens of the bacillus coli. Fish, too, caught two miles from land in four fathoms of water at flood tide and examined for the bacillus coli were found to yield the organism in every case Dr. Eyre does not attach undue importance to these preliminary investigations but they suggest, as he observes, the desirability, indeed, we would add, the necessity, on the *grounds of common justice to the public* and to the *oyster* merchant, of clearing up this point.

But to revert briefly to Professor McWeeney's admirable report it has to be said that generally speaking his findings agreed with those of Dr. Browne. There were, however, some notable exceptions. In one of these the bacteriologist was able to correct the epidemiologist; in another the bacteriologist failed in the first instance to discover bacillus coli in oysters obtained from a source admitted presumably by the epidemi- [illegible]

the Royal Commission on Sewage Disposal as to the value of bacteriological examinations was a thoroughly sound one and in arriving at its conclusions the Commission doubtless had before it the full report of Dr. Houston, the publication of which is anxiously awaited by all epidemiologists and bacteriologists. It appears to us that the report of the Commission is exerting a wholesome effect upon the unscientific use and application of experimental work which has not yet reached such a phase of stability as to justify its application to administrative measures, and all those familiar with the real merits of the problem will, we feel sure, agree with Sir H. A. Robinson and Mr. Stafford when they say, while according every possible credit to the excellent work of Professor McWeeney, "at the same time we think it right to state that in our opinion bacterioscopic or chemical examinations of samples taken from shell-fish layings cannot be regarded as a substitute for careful and intelligent local inspection, but rather as an aid in all but obvious cases of pollution." The precise value of such aid must, we take it, depend very largely upon the answer to be given to the three provisional conditions which have been set out by Professor McWeeney and to which we have already referred.

MEDICINE AND THE LAW.

The Legal Claim for Medical and Surgical Fees

THE conditions under which an action may be brought to recover fees earned by medical men are sometimes imperfectly understood as is shown by letters written from time to time to THE LANCET with regard to them. The law on the subject is contained in the following sections of the Medical Acts, 1858 and 1886. The Act of 1858 provided for registration and also that no one should recover fees for medical or surgical attendance or for any operation unless he proved at the trial that he was duly registered. Section 31 of this Act was, and for medical men registered before June 1st, 1887, may be said still to be, as follows:—

> Every person registered under this Act shall be entitled according to his qualification or qualifications to practise medicine or surgery, or medicine and surgery, as the case may be, in any part of Her [illegible]

It will be observed that this authorised registered medical *practitioners to practise and to recover fees according to* their qualifications only, and that it permitted and contemplated the possibility of a College of Physicians prohibiting not only its Fellows but its Members, a term which would possibly cover its Licentiates, from suing in courts of law for payment. The possibility of such a regulation as to Members being passed was not unlikely to deter young men from seeking the qualification to be conferred by a College of Physicians and, in fact, it is believed to have had the effect of increasing the number of *candidates for the qualification* of L S A. The Medical Act, 1886, provided for a qualifying examination in medicine, surgery, and midwifery for all persons to be registered thereafter under the Medical Acts. Having done so it defined the scope of their practice in these terms:—

> Section 6. On and after the appointed day[1] a registered medical practitioner shall, save as in this Act mentioned, be entitled to practise medicine, surgery, and midwifery in the United Kingdom and (*subject to any local law*) in any other part of Her Majesty's dominions and to recover in due course of law in respect of such practice any expenses, charges in respect of medicaments or other appliances, or any fees to which he may be entitled, unless he is a Fellow of a College of Physicians the Fellows of which are prohibited by by-law from recovering at law their expenses, charges, or fees, in which case any such prohibitory by-law, so long as it is in force, may be pleaded in bar of any legal proceeding instituted by such Fellow for the recovery of expenses, charges, or fees.

This it will be observed entitles all registered medical practitioners, subject to exceptions which are specified in other parts of the Act, to practise medicine, surgery, and midwifery and to recover *accordingly. The section,* moreover, recognises the restrictive powers of Colleges of Physicians only in respect of their Fellows. With regard to the question recently raised of prohibiting medical men from dispensing, it may be noticed that both the sections quoted recognise the right of the medical practitioner to charge for medicines *subject* in Section 31 of the Act of 1858 to his qualification. Under that section a surgeon could only charge for medicines when he *provided them in a surgical* case as subordinate adjuncts to surgical treatment. With regard to the limited application of Section 6 of the Medical Act of 1886, Section 24 of the same Act provides that:—

> This Act shall not increase or diminish the privileges in respect of his [illegible] appointed day[2] is [illegible]

Section 28 of the same Act repeals certain Acts of Parliament then in force or parts of them, including Section 31 of the Medical Act of 1858 quoted above, but with reference to this section provides also that such repeal "shall not affect anything done or suffered, or any right or title acquired or accrued, before such repeal takes effect, or any remedy, penalty, or *proceeding* in respect thereof." The net result of these enactments is that the medical man registered before June, 1887, has to consider the nature of his qualifications appearing in the Register and the nature of the services which he has rendered before bringing an action to recover fees. The medical man registered after June, 1887, is independent of all such conditions. Only if he is a Fellow of a College of Physicians which does not permit its Fellows to sue must he treat the reward of his work as a "*honorarium*"

---

[2] Ibid.

SANITATION IN THE BAKEHOUSE AND THE RESTAURANT KITCHEN.

IT was at the end of 1889 and the beginning of 1890 that we published a series of reports on "Bakeries and Bread-making." We first described the dangerous filth existing in underground bakeries not only in poor quarters but notably in the establishments of some fashionable London West-end confectioners and bakers. Then we alluded to the unhealthy nature of the work imposed on the journeymen bakers, the night work, the long hours, and the diseases prevalent among this section of the population. These details were followed by a description of the bakery in the Rue Scipion which provides all the bread consumed in the hospitals and which belongs to the Paris Municipality. Here there are no night work, no excessive work, good pay, and old age pensions. The bread is pure and cheap and it does not entail any expense on the ratepayer but, on the contrary, saves the public purse by providing the hospitals with wholesome food at something like cost price. We also gave an account of the coöperative bakeries of Vooruit, of Ghent, and of the Maison du Peuple of Brussels where model conditions prevail in regard to cheapness, purity, and sanitary surroundings in the making of the bread. There journeymen bakers have the eight hours day, no night work, plenty of light and ventilation, and better pay than in the ordinary bakehouses, and there is consequently much less sickness. This information gradually filtered through from our columns to the trade papers and the general press. It ultimately found an echo in proposals and speeches made in the House of Commons and the greater rigour shown in dealing with underground bakeries under the Factory and Workshop Act of 1901. Then the Factory Act of 1895 was passed forbidding the using of a "place underground" as a bakehouse unless it was so used before the passing of the Act and numerous by-laws have been issued by local authorities rendering the supervision of such places more and more severe. So there has been some improvement and the publicity which we gave to the subject has helped to bring this about.

After dealing with bread-making we published an article on Sanitation in the Kitchen,[1] in which we described the regulations issued by the Paris Municipality in regard to the restaurant kitchens. We also related how Dr. Regeard had taken action on behalf of the professonal cooks. The great prevalence of disease among them is the direct consequence of the unwholesome conditions under which they work and this was denounced by Dr. Regeard. Now to-day we find that Dr. W. Collingridge, as medical officer of health of the City of London, has issued a special report coupled with important and practical proposals in regard to the restaurant kitchens and the bakehouses of the City. The suggestion is that such establishments should have certificates given to them if their premises are in a satisfactory state. There is nothing new in the proposal. Silver is "hall-marked" and in many seaside places or other health resorts certificates are given to lodging-house keepers as to the condition of their drains, &c. Many owners of restaurants in the City have been called upon to carry out alterations and repairs and they feel that they should reap some benefit from such outlay. If they could exhibit a certificate it might attract customers. To the public, also, it would be a great advantage to know that the kitchens where the food which they eat is cooked have been examined by experts and put in order. Dr. Collingridge proposes that all the owners of kitchens and above-ground bakehouses should be told what are the requirements that would meet the necessities of the case and that if they complied with the specifications prepared by the corporation a sanitary certificate would be granted. But this is evidently not sufficient, for a place that is in a perfect state to-day may soon degenerate and become unwholesome. The inspections should be repeated from time to time and fresh certificates should be issued. It is thought that under this system the restaurant keepers and the bakers would be much more willing to carry out the requirements of the sanitary authorities and would devote more time and attention to the proper maintenance of the necessary standard of sanitary perfection. A somewhat similar way of proceeding has worked well in regard to houses let out as cheap tenements. These are exempted from the payment of inhabited house duty if the medical officer of health certifies that the tenements are kept up to the model sanitary standard established.

The sanitary requirements of tenements are, however, better known than those of bakehouses or restaurant kitchens. It will be, therefore, of practical interest to see what are the rules it is proposed to apply to the City bakehouses and restaurants. Now, in this respect, the first object is to scour and thoroughly to wash out the place. Therefore the walls and ceiling should be finished off with a hard, smooth surface made of impervious material so that it can be washed. The floor, for the same reason, should not be absolutely level but should slant slightly so that the water may easily drain away. The method suggested for dealing with damp walls is somewhat stringent. Another inner wall is to be built at least half a brick thick and separated from the damp wall by an open space also at least half a brick wide. This space is to be ventilated and drained. But such a supplementary wall would make the interior of the bakehouse smaller and the cost of space in the City will cause many to seek some other method of curing the dampness of their walls. This is the more likely as after all the remedy only masks the evil and does not in any way remove it. Of course, there are the usual stipulations as to the perfect soundness of drain-pipes and the various sanitary fittings. The bakehouses are to have a minimum height of eight feet and at least 1500 cubic feet of clear space between the ovens and any stored flour. For each person employed in the bakehouse there must be at least 400 cubic feet. As far as possible natural light should be used and when artificial illumination is necessary it should be either by electricity or by incandescent burners. Then we are told that the ventilation should insure a constant and sufficient change of air without producing draughts. It would be very interesting to know how this can be provided, for unless mechanical means are employed, with very elaborate methods of delivery and extraction of the air either the ventilation is insufficient or a draught is created. Nevertheless, we are told that the temperature must not exceed 80° F. except during the half hour after a batch of bread has been taken out of the oven. It will be more easy to ventilate, as proposed, the ovens themselves, so that the heat, steam, and sulphurous gases shall be conveyed straight to the open air instead of permeating the bakehouse, much to the injury of those employed there. Then the flour should not be stored in the bakehouse. There should be ample lavatory accommodation, but outside and well away from the bakehouse. If there are cisterns for the storage of water they should be fitted with dust-tight covers. Flour should not be put on the ground but on shelves at least 12 inches from the ground. All the dough troughs and heavy articles should stand on castors, so that they can be easily removed when the walls and floor are sluiced with the hose and jet which should be at hand. Shelves must stand out two inches from the wall and all unnecessary woodwork must be taken away.

In regard to the restaurant kitchens the same regulations apply as to the facilities for washing the floor and walls, for ventilating, for lavatories away from the kitchen, for draining, for the prevention of damp walls, for the removal of unnecessary woodwork, and so on. The minimum height of a kitchen should be eight feet and the capacity equal to 400 cubic feet for every person employed therein, and no kitchen must have less than a capacity of 1500 cubic feet. Where the kitchen is underground the inlets for ventilation must be at least 12 inches above the footway or the ground abutting upon the kitchen. Further, it is stated that when gas is used in the process of cooking means must be provided for carrying off the fumes generated and hoods must be placed over all stoves and ranges to carry off the fumes and heat Such hoods, of course, must communicate with the outer air by means of a shaft or flue. Naturally, also, the storage of food and all the scullery work, draining of plates, the shelves, &c., for saucepans and other utensils, should be provided for outside the kitchen. If this is not possible there should be a dwarf partition to separate the scullery work from the cooking. Then there must be proper bins for flour and other articles of food so placed as not to be exposed to dirt, dust, or moisture. Enamelled stoneware sinks should be provided, especially for the washing of vegetables. The metal bins for the reception of refuse must have tightly fitting covers and must be emptied every day. Great care should be taken to provide separately for each sex, near but outside the kitchen, wash-hand basins for personal ablutions. The kitchen wearing apparel should be hung up outside the kitchen and, in a word, every facility ought to be provided for maintaining the perfect cleanliness of both the kitchen and the cooks.

---

[1] THE LANCET, April 26th, 1890, p. 934.

These regulations, it will be seen, evidently contemplate the continued existence of underground kitchens. For the City, considering how the houses have been built, the immense value of the land, and the extreme cost of any radical alteration, it is presumably necessary to make the best of the evil conditions that prevail. Undoubtedly the late Sir B. W. Richardson was right when he urged that it was a fundamental mistake to place the kitchens in the basement of houses; the kitchens should be in the garrets rather than in the cellars. The picture given by the above regulations of air inlets 12 inches above the footway is not encouraging. In times of epidemic it has been noticed, especially in regard to cholera, that there was a greater number of cases among those who were regularly employed in the cleaning of boots. The boots worn by pedestrians are certainly more likely to come in contact with dejecta and to become the carriers of specific germs. That is why Mahomed, who was an eminent sanitary reformer, would not allow the faithful to enter houses of prayer with their boots on. In eastern countries it is the practice to leave the shoes or boots at the door when a call is made. As a compromise in regard to this custom, Europeans in Constantinople generally wear goloshes which they take off at the door when they make a call. Here, however, we have the crowded streets of the City where thousands of feet pass and repass, ever stirring the dust of the pavement, and within 12 inches of all these boots and feet and of this dust are the intakes of air for the ventilation of the kitchens. This dust-laden air will pass over the dishes and the saucepans and sprinkle them with the heavier particles of every sort of dirt brought in from the City causeways. This street dust will then be duly eaten by the frequenters of the restaurants. If it is impossible, really impossible, to abolish the underground kitchens then the air intakes that are on the level of the street should be provided with some method of filtering or of washing the air brought in. Otherwise these air intakes should consist of shafts that would bring the air down from above the roof of the building. It is difficult to justify the giving of a certificate for sanitary excellence to a kitchen which is ventilated with the air and dust collected within a few inches of the pavement of a city street.

In Paris the suspicions which it is so natural to entertain in regard to the restaurant kitchen have been met by many restaurant proprietors in a very radical and effective manner. The celebrated Duval restaurants made their reputation by simply placing the kitchen in the restaurant itself. Just as in England the customer may watch his steak on the silver grill, so can the much more elaborate cooking of the Duval chefs be observed by the intending diner. Indeed, a large proportion of the cooking in Paris restaurants is done in the presence of the customers. It has often been a matter of surprise that there are no imitations of the Duval restaurants in this country. English people, who know little about the culinary arts, apologise for the simplicity of their food by saying that they like to know what they are eating. At the Duval restaurants they can see what they wish to eat being cooked and the fact that the customer can watch the cook is a very effective guarantee for the cleanliness of the cooking.

In any case it is very urgent that all these problems should be taken in hand and that practical action should be attempted. Dr. Collingridge therefore is to be congratulated upon his initiative. As the difficulty of obtaining the services of domestic servants grows greater and as the number of persons living in flats and chambers increases the tendency will be to reduce housekeeping to its simplest expression. For this purpose dining at the restaurant may ultimately become as much the custom in London as it is in Paris. Consequently the importance of establishing an effective control over the sanitary condition of restaurant kitchens becomes a matter of growing concern and we are therefore glad to record the measures which the City Corporation is now contemplating. Their successful application will meet with general approval and will constitute a useful example for other local authorities.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 11, 1826.

ST. BARTHOLOMEW'S HOSPITAL.

Exceedingly rare case of Intussusception, wherein upwards of a yard of intestine was removed.

In every case of intussusception that has hitherto been published in the Journals, there has always been some questionable part, some deficiency of description connected with it, so as to leave a doubt whether the portion of substance brought away was really intestine or a tube of lymph, secreted from the internal surface of the intestines; and this very circumstance has led some medical men to become so sceptical as to question whether such an occurrence, as that of a loss of a portion of gut, ever happened. It is, therefore, with no little gratification that we have it in our power to remove any existing scepticism on such an interesting and fortunately rare disease, by reporting the following case:

A woman about the middle period of life, had been for some time labouring under a constipation of the bowels, and she in consequence sent for her medical attendant, who on the second day of his visiting her, had his attention directed to a slight protrusion which had taken place *per anum*. From the appearance which it presented on a superficial examination, he was induced to think it was a portion of the rectum, and as no particular swelling of the parts had as yet supervened, the tumour was readily returned.

The constipation, however, continued, and within a day or two she was seized with severe symptoms of peritoneal inflammation; there was pain over the abdomen, accompanied with a continual state of nausea and sickness, so that every kind of nourishment that was taken was instantly rejected. Just about this time a protrusion again recurred, and to a greater extent than at the former period; this induced the [illegible] ine the condition of the parts, [illegible] ly withdrew a small portion, [illegible] he continued in this manner [illegible] *one yard and three inches* [illegible] when the last portion was [illegible] s employed. The violent and distressing symptoms which had previously harrassed and tormented the patient, now, in great measure, subsided; still, however, pain was complained of in the abdominal region, and there was an occasional recurrence of nausea and sickness. A dose of castor oil was given the patient by the attendant surgeon, and to his great surprize he had the satisfaction to find on visiting her the next day that the bowels had acted for the first time since the commencement of the attack. On examining the evacuation it was found to present the appearance of a healthy and natural secretion. Small doses of sulphate of magnesia in mint water, were occasionally administered, and in a very short time the nausea and sickness subsided. The patient went on progressively improving to the eighth day, at which time the bowels had acted three or four times, and the general state of the patient was such as to induce a favourable prognosis of the case to be given.

To use the metaphorical language of John Hunter, however, "Nature took the alarm, conscious of her inability to sustain the extensive injury that had taken place, she gave up the contest;" and at the moment when the patient appeared to be going on favourably, life ceased.

Mr. Stanley assisted in examining the body, which we need not say was done in a most careful manner. It was found that the detached intestine was a portion of the ileum which had become intussuscepted (if we might be allowed to use such an expression) within the colon, violent straining attendant on the distressing symptoms under which the patient laboured, had in all probability greatly facilitated the descent of the gut. And that it did not arise from the force which was used in extracting it is abundantly proved, from the circumstance that the solution of continuity was discoverable. An inflammatory action had taken place about the caput coli, which had occasioned a secretion of lymph, thus completely agglutinating the two portions of intestine together; and from this agglutinated part had the separated portion of intestine been detached. The ileo-colic valve was entire. The mucous coat of the transverse arch of the colon was found to be in an inflamed state, and in two or three places small ulcerated spots were discoverable. The peritoneum was also inflamed, but not in a very remarkable degree.

The portion of gut which had been removed, was brought to the museum by Mr. Stanley, who showed it to the pupils the following Saturday. There can be no doubt as to its being intestine, since the valvulæ conniventes were very apparent, and moreover the coats of the intestine were divided, and shown. The valvulæ conniventes, as is usual, were found to be more numerous towards that portion which was nearer the jejunum.

Mr. Langstaff and Mr. Welbank, with several other respectable surgeons, and we believe Dr. Latham also, have seen the preparation, and it is unnecessary to say they are all thoroughly convinced of the fact of its being a portion of gut.

SMOKE PREVENTION AT GAS WORKS.

(A NEW PROCESS OF GAS MAKING.)

AN invention has recently been brought to our notice for carbonising coal for the production of gas which promises to do away with the smoke nuisance at gas works. The inventor, Mr. T. Settle of Exeter, has been conducting investigations in this direction for a considerable time and has at last been successful in producing a form of retort in which the carbonisation of coal can be carried out at a regulated temperature and under more scientifically correct conditions than have been possible before. In the ordinary method of carbonising coal the plan has been to use horizontal retorts usually charged by hand, and while it has always been known that by working in this way the results obtained were much inferior to those which ought to be possible in theory the method has held its own for general practical utility.

Probably everyone who has visited a gas works at charging time has noticed the waste of gas and the volumes of thick black smoke which escape when the fresh charge is introduced. This seems to be unavoidable when working by the old process and though very many attempts have been made from time to time to curtail the loss and to do away with the escape of smoke and crude gas the process remains to day much the same as it was in the earliest days of gas manufacture.

In the ordinary process of gas making after the charge of coal has been carbonised the retort door is opened and the coke is "drawn" by hand with long rakes. This is an exceedingly exhausting process to the stokers and is at the same time a cause of nuisance because, while the red-hot coke is being drawn out, tar drips down from the "ascension pipe" on to the red-hot coke and produces a thick smoke with an abundance of soot. After the coke has been "drawn" the stokers proceed to charge the retort by shovelling in coal, or in some works the charge is introduced more rapidly by means of a scoop operated either by mechanical power or by hand. In either case there is a certain unavoidable escape of gas and the retort is considerably cooled by the introduction of a large body of coal. At low temperatures there is a considerable formation of tar which has at the present time very little commercial value, whereas more gas and less tar are produced when the temperature rises. In the new process the temperature is kept constant throughout and what little tar is made can at will either be obtained as such or can be returned to the retort and completely gasified. The laborious "drawing" by hand is greatly simplified, as the retort is vertical and the coke falls out with very little manual labour. The charging is most ingeniously and simply carried out without any manual labour at all. The coal, in a state of fairly fine division (being what is generally known as "slack"), is placed in a hopper above the retort and is allowed to drop into it when required. Working in this way the temperature of the retort is not much affected by the small quantities of coal introduced and can be kept at the heat which is best for the production of gas and not being exposed to great changes of temperature the retort is less liable to crack.

As the result of a very large number of experiments by different observers it has been found that the saving of the gas ordinarily lost in the old method of charging and the gain owing to the temperature being maintained at the most favourable point throughout result in an increased yield of gas of no less than 30 per cent. above that obtained by the old method. This is, of course, a very considerable saving but there is another which from a financial point of view may be even more important and that is that the new process enables "slack" or small coal to be used profitably for gas making. This is a very great achievement, as up to the present it has not been found practicable to obtain such good results with "slack" as with larger coal. There have been a good many attempts in times past to get an increased yield of gas from coal and some of them were successful from this point of view but failed in some other important point, either through the apparatus being complicated or through the coke produced being soft and unsaleable. The coke produced by the new process is in every respect equal to the best coke obtained from horizontal retorts and the yield of ammonia, which is a by-product of some importance, is equal to that obtained by the old method.

In the new process there is absolutely no escape of gas during the charging or "drawing" and hence the process will be of particular value to works situated in or near populous districts.

ASYLUM REPORTS.

London County Asylum, Claybury (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 2398, comprising 996 males and 1402 females. The admissions during the year amounted to 445—viz , 180 males and 265 females. Of these, 373 were first admissions. Dr. Robert Jones, the medical superintendent, states in his report that a higher proportion of senile cases was admitted than during the previous year and that the proportion of cases of general paralysis among the admissions was unusually high—viz., 22 per cent. 28 per cent. of the admissions had a hereditary history of insanity, while alcohol was the cause of insanity in 27 per cent. Influenza appeared also to be a "more potent but subtle factor in the etiology of insanity than is usually recognised. Especially was this the case when the attack of influenza had been a mild one." The number of patients discharged as recovered during the year amounted to 157—viz., 60 males and 97 females, or 6·5 per cent. of the average number resident. The deaths during the year amounted to 223, or 9·3 per cent. as calculated on the same basis. Of the deaths, six were due to epilepsy, seven each to renal disease and bronchitis, 18 to dysentery, 21 to cardiac disease, 26 to epilepsy, 29 to senile decay, 29 to pneumonia and broncho-pneumonia, 38 to pulmonary and other forms of tuberculosis, 39 to general paralysis of the insane, and the rest to other causes. "More senile cases," says Dr. Jones, "died this year than in any year since the opening of the asylum ten years ago." Asylum dysentery attacked 26 males and 56 females and was the direct cause of death in 18 cases. "I consider overcrowding to be," adds Dr. Jones, "one of the most potent of the causes of asylum dysentery. ...... All cases of diarrhœa not yielding to treatment in three days are now segregated in a special isolation hospital." Two female patients admitted while pregnant gave birth to infants; one has since been discharged but the state of the other is unfavourable in regard to cure. The Commissioners in Lunacy observe in their report that the asylum was in excellent order throughout, that the wards were well lighted and cheerful, that the dormitories and bedding were in a thoroughly satisfactory condition, that the patients were neat and tidy in appearance, and that the medical case-books were carefully and intelligently kept. The committee of management states in its report that the work of testing and repairing the drains of the asylum has been completed, that the Claybury Hall or building for private patients has been connected with the fire-alarm system of the main building, and that additional fire-hydrants have been fixed to give better protection in case of fire The farm accounts show a profit on the year's working of £94 10*s* The sum of £7883 has been spent during the year in repairs, additions, and alterations.

London County Asylum, Colney Hatch (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 2490, comprising 916 males and 1574 females. The admissions during the year amounted to 477—viz., 186 males and 291 females. Of these

391 were first admissions. Dr. W. J. Seward, the medical superintendent, states in his report that among the cases admitted were 19 epileptics, 259 general paralytics, and 23 patients over 70 years of age. "Among the admissions were 55 aliens, of whom 47 were Jews. The number of Jewish patients at present in the asylum is 259, which is an increase of 15 on the number for the previous year." Of the causes of insanity in the admissions hereditary predisposition was found in 23 per cent. of cases, 13 per cent. (among the males 20 per cent) were due to alcoholic intemperance, and 14 per cent. of cases were due to anxiety, overwork, and mental strain. The number of patients discharged as recovered during the year amounted to 178—viz., 58 males and 120 females, or 7·1 per cent. of the average number resident. The deaths during the year amounted to 238, or 9 5 per cent. as calculated on the same basis. Of the deaths five were due to renal disease, 19 to bronchitis, 25 to colitis, 25 to cardiac disease, 30 to senile decay, 34 to general paralysis of the insane, 40 to pulmonary and other forms of tuberculosis, and the rest to other causes. Post-mortem examinations were made in 186 cases. Referring to the late disastrous fire at the asylum Dr. Seward adds: "A very large number of both the male and female members of the staff took part in the work of rescue and I cannot speak too highly of the discipline and devotion to duty which was shown by them under such a trying ordeal. Several narrowly escaped with their lives from the suffocating effects of the smoke which rendered the work of rescue very difficult. I am deeply thankful to be able to feel assured that all the patients who lost their lives were insensible, if not dead, from suffocation long before the flames reached them. In this connexion it may be mentioned that of the 269 patients who were rescued only one sustained any severe burns." A small isolation hospital which provides accommodation for six patients is completed. The asylum was free from enteric fever for more than a year but five cases occurred during the year and one sufferer (a nurse) succumbed to the disease.

farm buildings have been relaid and brought up to date, that the sum of £10,059 has been spent on additions, alterations, improvements, and repairs, and that the farm account shows a working profit on the year of £414.

London County Asylum, Hanwell (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 2554, comprising 998 males and 1556 females. The admissions during the year amounted to 497—viz., 235 males and 262 females. Of these, 411 were first admissions. Dr. R. R. Alexander, the medical superintendent, states in his report that cases of melancholia of both sexes greatly outnumbered those of mania among the admissions and that this has been the case for many years past. Hereditary perdisposition to insanity was found in 16 per cent. of the males and 12 per cent. of the females admitted, while alcoholic intemperance was found to be the cause of insanity in 16 per cent. of males and 20 per cent of females. The smallness of these percentages, adds Dr. Alexander, is due to the infrequency of visits from friends of patients owing to the prevalence of small-pox in the institution for a considerable time, so that information as to these causes was not forthcoming. The number of patients discharged as recovered during the year amounted to 173—viz., 80 males and 93 females, or 6·8 per cent. of the average number resident. The deaths during the year amounted to 222, or 8 8 per cent. as calculated on the same basis. Of the deaths three were due to renal disease, eight to colitis, 14 to bronchitis, 16 to cardiac disease, 20 to senile decay, 28 to pulmonary and other forms of tuberculosis, 62 to general paralysis of the insane, and the rest to other causes. Post-mortem examinations were made in 210 cases. There was no suicide, serious casualty, or inquest during the year. The Commissioners in Lunacy state in their report that the asylum continues to be maintained in very good order, that the wards, dormitories, and bedding were in a very satisfactory condition, and that the medical case-books and post-mortem records were well and carefully kept. Having regard to the recent lamentable loss of life by fire at Colney Hatch Asylum the Commissioners in Lunacy devoted considerable attention to the question of the safety of the nurses and patients residing in the temporary buildings in case of fire. Many recommendations were made which the committee of management is now engaged in carrying out. The committee of management states in its report that the sum of £6219 has been spent in additions, alterations, improvements, and repairs, that many alterations have been, and are being, carried out to provide additional exits from the building in cases of fire, that a second professional fireman has been appointed who is resident at the asylum, so that a trained fireman is always on duty, and that the installation for incandescent gas-lighting for which an expenditure of £550 had been sanctioned was now practically completed with satisfactory results.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Kingston-upon-Thames.—Mr. H. Beale Collins thinks that the coming into operation of the new Education Act is the most important event to be recorded in connexion with the public health and if the powers bestowed upon county and borough councils are administered with a due regard to the principles of preventive medicine we entirely agree. The first recommendation made to the town council of the borough is that the number of desks or places in the present schools should be reduced from 3138 to 2466, advice which we hope to see followed. Mr. Collins is clearly alive to the importance of physical training in the schools and he suggests that in addition to exercises on the Swedish system the Swedes should also be followed in the matter of the medical examination, weighing, and measuring of the children. He further advises that an assistant school attendance officer with the certificate of a sanitary inspector should be appointed. Certainly this step would be likely to insure the control of the council over infectious diseases, more especially in the case of diseases such as measles and whooping-cough, where a medical man is either not called in at all or only in the later phases of the illness. Mr. Collins thinks that the great safeguard against contracting tuberculosis is to render the body resistant to the germ by physical training, by an open-air life, and by rational food.

Chelmsford Rural District.—Dr. J. O. Thresh reports that the Local Government Board has approved certain by-laws by means of which it will now be possible under reasonable

of wood or of

districts that

nodel by-laws

somewhat inhibit building in rural districts and it will be interesting to observe whether this modified series will in fact lead to increased building in the Chelmsford rural district. The effect of the excessive rainfall in 1903 has had both a beneficial and a baneful influence in this district—beneficial in that it has replenished springs which formerly were low and baneful in that it has led to a somewhat remarkable outbreak of diarrhœa from the washing of surface pollution into an unprotected tank into which well water was pumped.[1] The incidence of the disease appears to have exerted itself almost exclusively upon the users of the Chelmsford borough water, or, rather, upon a certain section of that supply, and a considerable number of people, mainly over five years of age, were attacked. In that part of Chelmsford borough supplied by the implicated water about 1400 cases are believed to have occurred, while in the rural district to which the present

population of

were in all 14

e water-supply

		Deaths from diarrhœa during epidemic.
Chelmsford borough and Widford village.	5000 persons not using implicated water	0
	7700 persons using implicated water	14
	23,000 persons in the remainder of the union not using the implicated water	0

The outbreak had many points of interest and it is a good illustration of the dangers which are to be anticipated from the use of water liable to be fouled by surface washings. There are a sufficient number of similar outbreaks now on record to justify more attention being paid to this question

---

[1] Vide THE LANCET, Nov. 28th, 1903, p. 1519.

6·0 per 1000 of the population, estimated at 4.613,812 persons in the middle of last year. In the three preceding years the rates had been 7·7, 8·9, and 9·9 per 1000 respectively. Among the various metropolitan boroughs the lowest death-rates last year were 3·8 in Stoke Newington, 3·9 in Hampstead, 4·3 in Kensington and in the City of Westminster, and 5·0 in Greenwich; the highest rates were 6·9 in St. Marylebone, 7·0 in Wandsworth, 7·1 in Bethnal Green, 8·0 in Hackney, and 10·1 in Deptford. The prevalence of small-pox in London during 1903 showed a great decline from that recorded in the preceding year; the number of new cases notified during the year was 416, against 1702 and 7798 in the two preceding years. This disease was proportionally most prevalent in the City of Westminster, St. Pancras, Poplar, Southwark, Lambeth, Battersea, and Wandsworth. The number of small-pox patients admitted into the Metropolitan Asylums Hospitals was 414, against 1788 and 8455 in the two preceding years; four cases remained under treatment at the end of the year, against 666 and 14 at the end of the two preceding years. The prevalence of scarlet fever during the year under notice was considerably less than in the preceding year; the number of new cases notified during the year being 12,531, against 13,809, 18,390, and 18,258 in the three preceding years. Among the various metropolitan boroughs scarlet fever was proportionally most prevalent in St. Marylebone, Bethnal Green, Bermondsey, Wandsworth, Deptford, Lewisham, and Woolwich. During last year 10,808 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 10,734, 14,959, and 15,133 in the three preceding years; the number of cases remaining under treatment at the end of the year was 1606, against 2460, 3080, and 2327 at the end of the three preceding years. The prevalence of diphtheria during last year showed a marked decrease from that in the previous year; 7738 new cases were notified, against 11,994, 12,154, and 10,735 in the three preceding years. The greatest proportional prevalence of this disease occurred in St. Pancras, Hackney, Poplar, Wandsworth, Deptford, and Greenwich. The Metropolitan Asylums hospitals contained 734 diphtheria patients at the end of last year, against 1343, 1369, and 927 at the end of the three preceding years; the new cases admitted, which had been 8777, 9090, and 7988 during the three preceding years, further declined to 6158 last year. Enteric fever showed a considerably diminished prevalence during the year under notice, 2339 cases being notified, against 4306, 3195, and 3412 in the three preceding years; among the various metropolitan boroughs this disease was proportionally most prevalent in Stoke Newington, Hackney, Holborn, Shoreditch, Stepney, and Battersea. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1903 was 1247, against 2074, 1480, and 1806 in the three preceding years; 246 cases remained under treatment at the end of December last, against 403, 195, and 210 at the end of the three preceding years. Erysipelas showed the highest proportional prevalence during last year in Hackney, Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Deptford. The 233 cases of puerperal fever notified during the year showed a decline of 79 from the number in 1902; 21 cases belonged to Hackney, 19 to Fulham, 19 to Islington, 18 to Lambeth, 13 to Southwark, 13 to Wandsworth, and 10 to Stepney.

During the year under notice 69,737 deaths of persons belonging to London were registered, equal to an annual rate of 15 2 per 1000, against 18·6, 17·1, and 17·2 per 1000 in the three preceding years; the average rate in the ten years 1893–1902 was 18 5 per 1000. Among the various metropolitan boroughs the lowest death-rates last year were 10 0 in Hampstead, 11·1 in Lewisham, 12 4 in Wandsworth, 12·6 in Stoke Newington, 13·2 in Paddington, 13 3 in Greenwich, and 13·5 in Woolwich; while the highest rates were 18 2 in Bethnal Green and in Poplar, 18·4 in Bermondsey, 18 6 in Holborn, 19 4 in Shoreditch, and 20·3 in Finsbury. In the five groups of boroughs the rates of mortality were 13·9 in the west, 14·5 in the north and in the south, 18·3 in the east, and 19 0 in the central. To the principal infectious diseases, 8088 deaths were attributed during the year; of these, 2925 resulted from diarrhœa, 2046 from measles, 1627 from whooping-cough, 740 from diphtheria, 376 from different forms of "fever" (including three from typhus fever, 368 from enteric fever, and five from simple continued fever) 361 from scarlet fever, and 13 from small-pox. These 8088 deaths were equal to an annual rate of 1·76 per 1000; the corresponding rates in the three preceding years were 2·23, 2·22 and 2·21 per 1000 and and the decennial average 2·60 per 1000 Among the various metropolitan boroughs the death-rates from these principal infectious diseases ranged from 0·58 in Hampstead, 0 86 in the City of London, 0·96 in Lewisham, 1·00 in the City of Westminster, 1·10 in Woolwich, and 1·14 in Chelsea, to 2·24 in Bethnal Green, 2·22 in Fulham, 2·32 in Finsbury, 2·36 in Stepney, 2·90 in Shoreditch, and 2·99 in Poplar. The fatal cases of small-pox numbered 13, against an average of 200 in the ten preceding years; of these 13 cases, four belonged to Stepney, four to Lambeth, three to the City of Westminster, and two to Poplar. The 2046 deaths referred to measles showed a decline of 505 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Battersea. There were 361 fatal cases of scarlet fever registered last year, against an annual average of 784 in the ten preceding years; the highest death-rates from this disease were recorded in St. Marylebone, St. Pancras, Finsbury, Poplar, Bermondsey, and Deptford. The deaths from diphtheria, which had averaged 2170 in the ten preceding years, declined last year to 740; among the various metropolitan boroughs the greatest proportional mortality from this disease was recorded in St. Marylebone, Hackney, Bethnal Green, Poplar, Deptford, and Greenwich. The 1627 fatal cases of whooping-cough showed a decline of 435 from the corrected average number; this disease was proportionally most fatal in Kensington, St. Marylebone, Islington, Finsbury, Poplar, and Battersea. The 376 deaths referred to different forms of "fever" were 292 below the corrected average in the ten preceding years; among the various metropolitan boroughs the highest "fever" death-rates were recorded in Fulham, St. Marylebone, Stoke Newington, Hackney, Finsbury, the City of London, Shoreditch, Poplar, Southwark, and Battersea. The 2925 fatal cases of diarrhœa showed a decline of 754 from the corrected decennial average; the greatest proportional mortality from this disease occurred in Fulham, Shoreditch, Stepney, Poplar, and Southwark. In conclusion, it may be stated that the aggregate mortality in London last year from the principal infectious diseases in the aggregate was 32·5 per cent. below the average.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 130 per 1000, against 158, 148, and 139 in the three preceding years. The rates of infant mortality in the various metropolitan boroughs ranged from 88 in Hampstead, 92 in Lewisham, 95 in Holborn, 96 in St. Marylebone, 108 in Woolwich, and 109 in Wandsworth, to 142 in Chelsea, 145 in Kensington, 148 in Southwark, 154 in Poplar, 158 in Bermondsey, and 171 in Shoreditch.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

THE undermentioned Majors to be Lieutenant-Colonels (dated Feb. 2nd, 1904):—R. J. Geddes, D.S.O., D. V. O'Connell, A. Dodd, G. Wilson, J. M. Reid, T. B. Winter, F. S Heuston, C M.G, G. F. Gubbin, M. O'D. Braddell, J. J. C. Donnet, and H. M. Sloggett.

Major J. Will is seconded for service under the Foreign Office (dated Feb. 20th, 1904). Captain F. S. Walker is placed on temporary half-pay on account of ill-health (dated Feb. 19th, 1904).

Lieutenant-Colonel J. G. Harwood is granted the temporary rank of Colonel whilst officiating as Principal Medical Officer of the Poona District. Lieutenant Colonel P. Mulvancy is appointed to the medical charge of the Princess Louise Hospital at Alton, Hants.

VOLUNTEER CORPS.

Rifle: 1st Roxburgh and Selkirk (The Border): George McKellar to be Surgeon-Lieutenant (dated March 5th, 1904). Brigade-Surgeon-Lieutenant-Colonel E Jones, Senior Medical Officer, Welsh Volunteer Infantry Brigade, resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated Jan. 22nd, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Glasgow Companies: Captain D. Christie, *from*

Argyll and Sutherland Brigade Bearer Company, to be Captain (dated March 5th, 1904). The London Companies: Lieutenant Colonel and Honorary Colonel J. E. Squire resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 5th, 1904) The Manchester Companies: The undermentioned gentlemen to be Lieutenants: Wilfred Edwin Rothwell (dated March 5th, 1904), and Alfred Francis Thompson (dated March 5th, 1904).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

Sussex and Kent: Captain C. J. Jacomb-Hood is appointed to command under paragraph 55A Volunteer Regulations, vice Major J. Turton, appointed Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade (dated Feb. 3rd, 1904).

THE REPORT ON THE HEALTH OF THE NAVY FOR 1902.

Some excellent reading will be found in the present volume in an article by Deputy Inspector-General Theodore J. Preston, R.N. (retired), under the heading of a "Report on Journals of Medical Officers examined at the Public Record Office, extending from 1793 to 1856" Unfortunately, as it happens, the medical officers of those times had a distaste for clerical work but this did not arise from the want of any interesting material. The extracts are, speaking generally, very short and the information is very scanty but what there is is curious and often quaint and interesting. Taken as a whole, Deputy Inspector-General Preston's paper gives a survey of the state and progress of the naval medical service within the dates specified. As a sample there is a very brief, and therefore disappointing, reference to Admiral Nelson's gunshot wound and amputation of the right arm in the journal of the *Theseus*, July 24th and 25th, 1797, and subsequently on August 20th in the journal of the *Seahorse* In this connexion it will be remembered that THE LANCET [illegible] an interesting communication [illegible] The notes and extracts from [illegible] subjects, such as the constitution and *personnel* of the medical service, medical, surgical, and sanitary matters, epidemic and endemic diseases, food, clothing, and water-supply.

MEDICAL OFFICERS OF THE GUARDS.

A Royal Warrant has been issued to the effect that "All regulations authorising the transfer of an officer of our Royal Army Medical Corps to our regiments of Foot Guards shall be cancelled. Medical officers who have already been gazetted to our regiments of Foot Guards shall elect, within such time as may be prescribed by our Army Council, whether they will remain therein or be transferred to our Royal Army Medical Corps. Medical officers who elect to remain in our regiments of Foot Guards shall be eligible for promotion under Article 383A of the Pay Warrant up to, but not beyond, the rank of Surgeon-Lieutenant-Colonel. Those who elect to be transferred to our Royal Army Medical Corps shall take rank and seniority therein as follows:— A Brigade-Surgeon-Lieutenant-Colonel—as a Lieutenant-Colonel selected for increased pay with seniority from the date of promotion to his present rank. A Surgeon-Lieutenant Colonel—as a Lieutenant-Colonel not selected for increased pay with seniority from the date of promotion to his present rank. A Surgeon-Major—as a Major, with seniority from the date of his original promotion to the rank of Surgeon-Major or Major."

THE ARMY ESTIMATES.

Mr. Arnold-Forster must have found himself in an unusual and somewhat difficult position on the occasion of his introducing the Army Estimates in the House of Commons. The present is a period of transition, indeed, almost of revolution, so far as the army and the War Office are concerned The War Minister spoke warily, but nevertheless favourably, of the reports of the War Office Reconstruction Committee and it seems nearly certain that, so far as all the main principles are concerned, the committee's recommendations will be adopted by the Government, although strongly opposed by Sir Henry Campbell-Bannerman. Mr. Arnold-Forster added nothing to our knowledge, however, about the intentions of the Government regarding the position of the Army Medical Service under the new scheme. The Army Estimates show a reduction of some £8,000,000, attributable mainly to the expenditure on the Boer war having come to an end and, on less satisfactory grounds, to a reduction in the strength of the Foot Guards and recruiting generally.

RUSSIAN ENGINEERS' SPLENDID CONTRIBUTION TO THE RED CROSS SOCIETY.

The directors of the Putiloff Engineering Works of St. Petersburg, the Krupps of Russia, are placing a sanitary infirmary train at the disposal of the field forces in connexion with the war in the Far East. The cost of this train, says the *Novoe Vremya*, will be over 100,000 roubles (£10,000). It will consist of an engine, a tender, and ten wagons and is at the present moment being rapidly got ready in the special model factory of the firm. The latest improvements have been introduced into the fittings of the wagons for removing the seriously wounded to the smallest detail and everything in connexion therewith answers to the latest requirements of science and the exactions of clinical practice and experience. For the medical staff, dispensary, kitchen, &c, special wagons are fitted and all is arranged to yield the greatest comfort and practical use.

RUSSIAN MILITARY HOSPITAL TRAIN.

On Feb. 24th, says the *Novoe Vremya*, the Russian Empress inspected the military sanitary train No. 13 for the seat of war, consisting of 13 wagons. Of these two are reception wagons for diagnosing cases, four are fitted with "Kruger" frames for the seriously wounded, two are for the slightly wounded, and one is for officers. In one wagon there is the kitchen and there is one set apart for the servants. The train was fitted up in the Alexandrovsk factory of Nikolaevsk in five days. A senior medical officer, five sisters of mercy, and 30 field medical officers from the Nikolaevsk Military Hospital will go with the train.

"Audi alteram partem."

ON PARACENTESIS AND THE USE OF THE ASPIRATOR IN PNEUMOTHORAX.

To the Editors of THE LANCET.

SIRS,—In a short article on the above subject which appeared in a recent issue of THE LANCET several important questions are raised upon which, as my name is there referred to, I should like to make some comment.

Strange as it may seem, pneumothorax is not always attended by urgent symptoms. The urgent symptoms are not merely mechanical in origin but depend chiefly upon the embarrassment and physiological disturbance in both the respiration and the circulation in the lungs, for though the mechanical conditions remain the same the urgent symptoms gradually subside if the lungs and heart have time to adjust themselves to the altered conditions. The greater the disturbance the more severe the embarrassment and the more severe the symptoms. Thus the paradox is explained that the symptoms of pneumothorax are the more severe the more healthy the patient has previously been. *Per contra*, in phthisis, for example, pneumothorax is not altogether uncommonly discovered by accident, as there may be no symptoms to mark its occurrence, for it makes but little difference to the condition of respiration whether the one lung be useless because it is tuberculous or because it is collapsed Yet even in persons apparently healthy pneumothorax may be latent—i.e., it may occur without marked symptoms.

In traumatic pneumothorax, with which especially the article referred to dealt, the symptoms are almost invariably severe, but then the diagnosis is not so easy. Rupture of the diaphragm may permit the passage of some of the abdominal viscera, the intestines, of course, chiefly, into the pleural cavity and will give rise to the same mechanical conditions and similar symptoms as pneumothorax. The diagnosis could only be made by careful physical examination of the chest and abdomen but usually the patients are too ill to stand much investigation.

When pneumothorax occurs not only is the one lung completely collapsed, but owing to the displacement of the mediastinum and heart the other lung, too, is partly collapsed, so that the total respiratory capacity [illegible] be reduced to about one-third of the normal. With [illegible] may be the [illegible] difference [illegible] sturbance is [illegible] is due to [illegible] so sudden, while in pleuritic effusion it takes place gradually, so that the rest of the lung has time to adjust itself to the change of conditions.

Again, we know that the great danger in pneumothorax is in the first few hours. Some patients die at once—from shock as it were; others die after some few hours of intense suffering. But the longer life is maintained the greater is the chance that the urgency of the symptoms may subside. With each hour of continued life the prospects improve. After the first 24 hours the dangers to life are not so much those of dyspnœa as of the complications which are likely to arise, chiefly serous or purulent effusions.

When pneumothorax occurs the lung on the affected side contracts by virtue of its own elasticity and theoretically the contraction may continue till the one lung is completely collapsed and lies like a flattened pancake round its root, while the contraction of the other lung will draw the mediastinum far over into the non-affected side. However, in those cases in which the air is admitted to the pleura by a free incision through the chest walls we see that this does not in fact occur. On the contrary, owing to the cough and expiratory efforts the lung on the incised side is kept moderately expanded or may even nearly reach the chest walls and in these circumstances we know that no urgent symptoms arise. Otherwise the opening of the pleura would be a very serious affair. Hence it would be quite justifiable in cases where life was in danger from the severity of the symptoms to relieve them by laying the side freely open, thus giving the air in the pleura free vent and permitting the lung partially to re expand.

Hesitation would rightly be felt before resorting to this heroic expedient on account of the risk of an empyema resulting and preference would be given in the first place to paracentesis. The object of paracentesis is to give the mechanical relief required, but it often happens that the relief is only temporary. The symptoms soon become urgent again. A second paracentesis has to be performed. It may be also a third or fourth. As a rule the relief becomes greater each time and more lasting and in the end the symptoms lose all urgency until perhaps after some days effusion forms and dyspnœa returns, but even then the dyspnœa is of gradual onset and the symptoms are not urgent. Where one paracentesis is not sufficient the cause is to be found in the fact that the opening in the lung is still patent. When it has closed no more air will enter the pleura and the relief given by paracentesis will be permanent till fluid forms. This shows at once the undesirability of employing the aspirator. The suction employed will stretch the lung and put a strain on the weak spot which may have just closed. This would then be reopened and air would reaccumulate in the pleura immediately the needle was removed. Beside this there is the risk of the suction of the aspirator drawing into the pleura some infective secretion from the lung and thus increasing materially the risk of empyema. For these two reasons the aspirator should never be used in simple pneumothorax; it is unnecessary and, more than that, dangerous. If repeated paracentesis fail it would be safer to proceed to incision. Practical experience shows, however, that incision hardly ever becomes necessary and simple paracentesis, repeated if required, is almost always sufficient.—I am, Sirs, yours faithfully,

SAMUEL WEST, M.D. Oxon., F.R.C.P. Lond.,
Physician to, and Lecturer on Medicine at, St. Bartholomew's Hospital.
Wimpole-street, W., March 5th, 1904.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES.

To the Editors of THE LANCET.

SIRS,—Professor J B. Farmer and Mr. F. Cavers, B.Sc. Lond., lecturer in biology at the Technical School, Plymouth, inform me that parthenogenesis is known in plant tissues that have undergone a "reducing division." That the phenomenon of self-fertilisation may prove to be connected with the powers of a metastatic growth to mimic the primary is speculation and may merit observation. The heterotypical cell divisions observed by Professor Farmer and his colleagues and Dr. E. F. Bashford and Dr. J. A. Murray (and which can be seen without difficulty in sarcomata and carcinomata by appropriate methods of fixation and staining) indicate that there is a structural change common to all malignant (atypical) neoplasms at one period of their existence. This is not known in innocent (typical) tumours. I submit that there is also clear microscopic evidence of the transition of sarcomatous forms of cells to those of epithelial forms. In support I mention two instances of growths in which such cell transitions are obvious to me in a careful examination of several sections. The one was a sarcoma of the breast in a woman, aged 52 years, under the care of Mr. C. Whipple at the South Devon Hospital. There were many intracystic growths the columnar cells of which in places were continuous and passed by gradual transitions into large sarcomatous elements. It was the "adenocystosarcoma" of Erichsen, Beck, and Raymond Johnson. Again in a huge diffuse melanotic sarcoma of the liver in a woman, aged 52 years, under the care of Mr. W. L. Woollcombe, the spaces between the hepatic cells were stuffed with rounded pigmented cells of varying sizes. A pigmented mole over the seventh right intercostal space showed pigmented cells in the cutis similar to the smaller ones seen in the liver. I regard the cells in the liver as showing transition from small endothelial to large sarcomatous elements (I place pigmented moles of this nature under the group of endotheliomata on the same grounds that Raymond Johnson and Lawrence place "parotid tumours" under this heading, and remembering the faculty of the liver of intercepting and nourishing new growth I look on the mole as primary). Similarly, H. D. Rolleston and O. Grünbaum note on a perithelioma of the cheek "striking features are the transition from cells of a sarcomatous type to cells exactly resembling columnar epithelium" (this was despite the use of selective "epithelial" stains[1]).

This second link in the chain of atypical growths is not a true metaplasia (defined by S. G. Shattock and C. A. Ballance, quoting Virchow, as the transformation of one normal tissue to another). It is a feature, to my mind, to which attention has been insufficiently directed and appears analogous to those powers by which epithelial and sarcomatous tissue are formed from "indifferent" tissue (e g., in carcino-sarcoma, in cylindroma carcinomatode, in adeno-sarcoma—the group of tumours excellently designated by H. Snow and C. P. White as blastomata.[2] It approaches in nature true heterology (Virchow). What bearing has it, if any, on the nature of the mitoses? Special observations of such growths are necessary before the question can be answered, but it appears to indicate a previous "sexual" change, thus allowing the succeeding generations of cells to be atypical, under certain stimuli. The heterotype mitoses may be merely terminal phases in the "life cycle of cancer cells" (Bashford) or of sexual cells (Farmer), as in plants and animals. May it not be that cancer is an exhibition of sexual and asexual phases in its life cycle, dependent on environment and intrinsic potentialities, as is the case with protozoa (e.g., malaria), to a colony of which it is compared? The sexual stage may be reinforced by parthenogenesis, nuclear conjugation, &c. We are as yet unaware of the forces (? chemical) which must determine and limit orderly cell growth and which are presumably neutralised in malignant tumours.[3] In a knowledge of these may lie the secret of prevention and remedy.

I am, Sirs, yours faithfully,

F. BUSHNELL, M D Lond, D.P.H. Cantab,
Honorary Pathologist in Charge of the Clinical Laboratory,
Feb. 27th, 1904. South Devon Hospital, Plymouth.

"FILARIA PERSTANS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 5th Dr. H. C. Bastian contributes a paper on the anatomical characters of the so-called filaria perstans and on the mode of infection thereby, part of this being a reply to my paper of Feb. 13th, where I discussed the suggestion that this filaria belonged to the genus tylenchus. There are several points in Dr. Bastian's paper I am sorry to say I cannot again agree with, and as they are of some importance I make this an excuse for again taking up the subject. Dr. Bastian states that I have supposed the figures of tylenchus obtusus in his former article were embryonic forms; this, however, is not the case. What I stated was "that the author had fallen into a misconception respecting the anatomy of the adult and embryonic forms of this filaria," by this meaning *filaria perstans*, and that he was comparing the adult forms of his tylenchus with the embryonic or larval forms of filaria perstans which to my mind was not permissible.

---

[1] Transactions of the Pathological Society of London, vol. liv. p. 353; vol. xlvii., 1896, p. 259; THE LANCET, May 31st, 1902, p. 1562.

[2] THE LANCET, Feb. 15th, 1902.

[3] Adami: Yale Medical Journal, 1901.

The points, however, which I specially wish to lay stress on are: (1) the statement that the information that exists concerning the anatomy of filaria perstans is scanty; and (2) the remarks regarding the mode of infection. As regards the first Dr. Bastian states: "In order to ascertain the genus to which a nematode belongs we want descriptions of the adult worms containing, in addition to mere size and external form, particulars as to the nature of the mouth and pharynx, the relative length of the œsophagus and the number of swellings, if any, in its course, together with the situation of the anus, the character of the ovarian tubes, the situation of the vulva, the shape of the male spicules and accessory pieces, as well as any other details that may be recognisable"

I have already[1] described the adult and embryonic forms of filaria perstans in detail and anyone who wishes to read this description may refer to that paper. It will be sufficient here to state that the information relative to the anatomy of this filaria is well known and the answers which I shall now give to Dr. Bastian's queries show this. The mouth of the adult filaria perstans is simple and circular, there are no papillæ nor is there a spine. (The fang or spine was not mentioned in my original paper as there is no such thing in the adult.)

Similarly the pharynx and œsophagus were not specially mentioned as there is nothing peculiar about them. They form a simple tube which merges insensibly into the intestine. There are no swellings on either of them. The course and termination of the intestine were described as follows: it extends almost throughout the entire length of the worm, ending on the concavity of the curve of the tail, in the female at the apex of a slight bulge on the cuticle, in the male at the general level of the cuticle, with four pairs of pre anal papillæ in front and one pair behind, with two unequal spicules, distant respectively from the tip of the tail 0 160 millimetre for the female and 0 120 millimetre for the male. The ovarian tubes were also described and the situation of the vulva accurately given—e.g., 1·22 millimetres from head. This brief *résumé*, I think, disproves the statement "that almost all internal anatomical details concerning the adult forms of filaria perstans appear up to the present to remain unknown." The anatomy of the embryo is equally well known. At the extremity of the head is the little spine or fang which in the living forms may be seen alternately pushed out and then retracted, it measures under 1 μ in length and naturally requires a high magnification to demonstrate it. The other anatomical features are described in my original paper.

As regards the mode of infection and the question of an intermediate host Dr. Bastian is peculiarly unfortunate in his statement that the embryos of filaria nocturna may live and advance slightly in development in the mosquito up to the fourth or fifth day, when the insect then dies and liberates them into the water. Surely the writer has studied the recent work on the life-history of mosquitoes and that on the metamorphosis of the filaria and its escape from the proboscis of the mosquito. This recent literature is so fresh in the minds of everyone that it would only be wasting valuable space going over it all again. It will be sufficient to pass to conclusions, then, and sum up as follows. 1. The anatomy of filaria perstans (adults and embryos) is well known. It is a typical filaria, resembling filaria nocturna and filaria demarquaii. 2 From the analogy of the metamorphosis of filaria nocturna in culex fatigans and other mosquitoes, filaria immitis in anopheles maculipennis (Grassi) and in culex ciliaris (Bancroft), and filaria recondita in pulex serraticeps (Grassi), it is exceedingly probable that the embryos of filaria perstans also find their way into some suitable blood sucking insect where they undergo a metamorphosis and then eventually pass to a fresh host.

I am, Sirs, yours faithfully,

GEORGE C. LOW, M.A., M.B., C.M. Edin,
Superintendent, London School of Tropical Medicine.

Albert Docks, E., March 7th, 1904.

THE BEARING OF THE WAR OFFICE CHANGES ON THE FUTURE OF THE ROYAL ARMY MEDICAL CORPS.

To the Editors of THE LANCET.

SIRS,—There can be no doubt in the minds of those conversant with the medical wants of the army of the importance of the point you raise in the leading article in THE LANCET of Feb. 27th, p. 588, under the heading of War Office Changes, on the future status of the Director-General in the new Army Council. So far as the present indications go, it seems probable that this official will be deprived of the position he now holds in the Army Board under Mr. Brodrick's scheme, yet until we have Part 3 of the new army scheme, which will embrace the position of the Army Medical Services, before us, and which "will shortly be ready for submission" by the committee, we cannot be certain of the full intentions respecting him. The ruling principle of this committee seems to be to bring the Army Council as far as possible into conformity with the Naval Board and should this principle hold good for the medical service there is every probability of a grave retrogressive step being taken. One prominent and potent defect in the Army Medical Department in the past was that it was placed under the Commander-in Chief with a Director General selected practically by him and to all intents his agent in military medical affairs, the department thus being but a subordinate section of the combatant branch of the army and having but little voice and less power in its own organisation, working and needs; and the resultant of this anomalous arrangement was shown in the condition to which it was brought prior to the formation of the existent Royal Army Medical Corps, the responsibility for the defects observable in the South African war, with all their sad attendant outcomes, lying beyond all reasonable doubt at the door of the officials filling the posts of Commander-in Chief and Adjutant-General The formation of the Medical Advisory Board by Mr. Brodrick and the improved status of the Director General through his inclusion in the higher army councils gave strong grounds to the inference that at last the medical needs of the army had obtained a power of expression and a prospect of practical support hitherto denied them, but should the retrogressive change now outlined be carried out it is apparent that the Royal Army Medical Corps, placed under one or other head of the new Army Council, will be again relegated to the miserably weak and subordinate position previously occupied by it. A belief in a capacity to organise and administer such a professional body as an Army Medical Corps, irrespective of guidance by those who have both professional ability and practical experience of army needs, seems a fixed ingredient in the minds of War Ministers and military officers, and the apparently proposed step of the present committee will do much to still further confirm this idea to the detriment of the service in question. So far the parallelism in the course taken after the Crimean war and the more recent South African war is complete—the same outburst of public indignation, the same exposure of medical deficiencies to meet army field needs, the same undeserved blame falling on the department and its professional head these being made the scapegoat for War Office and military incompetency to properly administer that which they had undertaken, the same official inquiry followed by schemes to rectify defects and to promote improvements, similar expressions of intentions of War Ministers to make the future state of this service all that was desirable, improvements of conditions for attracting a better professional class leading also to an actual competition for posts offered, though not to the same degree as in 1861, the same initiation of changes not suggestive of progress from the adopted scheme on change of the War Minister, and now apparently the same prospective intention to renew the subordination of the professional head to the military section. To those older ones among us who were led into the adoption of a military career by the improvements wrought after the Crimean war and the inducements then held out, and who subsequently found all their hopes frustrated and the ground of advancement cut from under their feet by the whittling away process put into operation by the military authorities and the apathy or impotence of their professional head, the marked importance of prevention of any further extension of this parallelism is self evident; and as in the past the main help in extracting the department from the "slough of despond" has come from the general professional body, so now the Corps must look to it, and especially the professional members in Parliament and the civil members of the Advisory Board, to present a strong front against the retrograde innovation which is apparently threatened in the composition of the new Army Council by the exclusion from it of the professional head, the Corps itself being markedly curtailed in its power of expression by the conditions under which it exists.

I am, Sirs, yours faithfully,
FRANCIS H. WELCH,
Surgeon-Colonel (retired) M.S.
Lee, Feb. 29th, 1904.

THE IRISH BRANCH OF THE BRITISH DENTAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—A careful study of the judgment given in the Court of King's Bench, Ireland, in the test case of "O'Duffy *v.* Jaffe" will convince any thoughtful man that there are principles and rules therein laid down the importance of which it would be indeed hard to exaggerate. Not alone are existing laws shown to be totally inadequate for the protection of the public from the danger and fraud of unqualified practice (whether dental or medical), but the road is clearly demonstrated by which, if it be not blocked by the Legislature, trickery and deception may even further invade the realm of public interests in professional life.

Briefly stated, the case was as follows. The Irish branch of the British Dental Association determined to bring to an issue the question, which had long been let go by default, whether the restrictions and penalties imposed by the Dentists Act of 1878 upon "persons" using the title of "dentist"—i e., without being registered—did or did not apply equally to a company or corporation as to individuals; and to obtain instead of "counsels' opinion," which had up to then been considered conclusive, a definite and binding legal pronouncement. They accordingly, as a test case, prosecuted for taking and using the title "Surgeon Dentists," and thus infringing the Dentists Act, "Jaffe, Surgeon Dentists, Ltd.," a company which consisted of two drapers, four married women, and a dental mechanic, none of whom possessed any dental qualification whatever. The case was heard by the local bench at Limerick in May last and, being dismissed, was carried by the plaintiff to the King's Bench. We send you herewith an official copy of the arguments advanced by counsel on both sides and the judgment delivered by the court after some three weeks' deliberation upholding the magistrates' decision.

We would invite a careful consideration of this judgment under three headings. 1. The court unanimously held that the word "person" in the Dentists Act did not include a company or corporation, and a company or corporation can therefore assume with impunity a misleading title, announcing a professional qualification the assumption of which by an individual would subject him to a penalty of £20. The grounds of the decision appear also to apply just as much to the Medical Act and the veterinary surgeons are also affected by it. The public, ever gullible, can thus be legally imposed upon by a company with a high sounding name which an individual (without six "dummies" behind him) would only assume at his peril. Further, not only can a company formed "*ad hoc*" play these pranks with the public but any existing company whose memorandum does not preclude such a thing may boldly assume any medical or dental title; for instance, the Army and Navy Stores would not come within the penal provisions of these Acts by assuming the description of physicians, surgeons, or dentists.

The second point in the case to which we desire to invite attention is this: counsel for "Jaffe, Surgeon Dentists, Ltd.," ingeniously put forward a further line of defence. The point raised was this: "The defendants have added nothing to their name; 'Jaffe, Surgeon Dentists, Ltd.,' is their name." How this argument impressed the court was shown by the Lord Chief Justice asking the following question: "If a man be born with the name 'Dentist' can he be prosecuted under this Act for using his name?—e.g., 'John Dentist'"? The significance of the defence was, therefore, not lost sight of and in the formal judgment of the court the point was decided as follows:—

The Lord Chief Justice (Lord O'Brien) said: "Person, I think, means a person who having one name takes another name or description, that is a natural person who has his own name and adds to it another name or description. It would seem to me not to include a company which comes into being with a name and adds nothing to it." Judge Gibson said: "The question before us is, whether a company, part of whose registered name is 'Surgeon Dentists,' by using that name committed an offence under Section 3 of this Act. The Act was never designed to apply to a corporation at all or to prevent a limited company from using its own proper name in which it was registered." Judge Madden agreed in the judgment of the court without specially referring to this point.

The case being on the criminal side of the court no appeal could be taken from the decision. This, then, being the law it appears that any fraud or deception on the public by a company, involving the assumption of a false or misleading title or name as of doctor or dentist, can be, and is, legalised by the irresponsible action of the Board of Trade in registering as a company, without question, any such name, title, or description which is presented to it; for, be it understood, the Board of Trade has no power to question or refuse any title brought to it for registration as a company saving only when such title has been already appropriated by some other company, and this registered title, though knowingly and wilfully intended to deceive by those who form the company, becomes forthwith the "proper name" under which the company "came into being"; its right to the use of which is as clear and indisputable as the right of Lord O'Brien's supposititious "John Dentist" to the use of his own patronymic. The hall porter from the hospital may then, should he desire it, rest secure in the name of "Sir Peter Smith, Doctor and Surgeon," and the bottle-washer in the pharmacy may undisturbed prey upon the public as "Sir Ebenezer Dodd, M.D. Lond." An individual would be liable to penalties and imprisonment, but on constituting himself a "company" by virtue of six "dummy" names behind him, under the ægis of the Board of Trade, the company or the individuals who compose it are beyond the reach of all penalties. In fact, anyone may gull the credulous under a name, with the addition of doctor, physician, surgeon, dentist, veterinary surgeon, or any other "proper name" which may suit his purposes, and under which he may elect to "come into being." To the lay mind there is some difficulty in seeing where the line is to be drawn or what limit exists to the assumption of titles by a "one man company." All one has got to do is to form himself into a "one man company."

The third important point in the judgment is the outspoken opinion of the court on the position as it stands and the judicial suggestion of a remedy. "Before, as well as since, the Dentists Act," said Lord O'Brien, "the Legislature has not infrequently failed in its policy and object owing to the inappropriateness and inadequacy of the language it employed. The ingenious have often invented, and I daresay will often invent, devices to get out of Acts of Parliament. ...... We cannot import the words which are necessary to hit the device and reach the mischief."

Judge Madden says: "If the general intention of the Legislature in regard to the protection of the public has been frustrated, and I believe it has, this is a necessary consequence of the language that has been employed." Further on he speaks of "the mischief against which the present prosecution is directed," and finally crystallises the suggestion of himself and his colleagues in these words: "The Legislature, if it thinks fit, can pass a statute specially directed against the mischief which has recently come into existence."

The importance of enlisting the aid of your valuable journal in rousing public opinion amongst professional men and also amongst your colleagues of the lay press, and drawing attention to the incalculable effect of this judgment of the Irish Court of King's Bench, must be our apology for making such a large demand upon your space, and we feel convinced that when the facts come to be widely known to the profession and the public such pressure will be brought to bear upon Parliament as will insure the effectual ending of this anomalous condition. We are advised that a short Act of Parliament providing that the penal clauses of the Medical, Dental, and Veterinary Surgeons Acts, under which unqualified persons are prevented from taking or using [illegible] veterinary surgeon, &c., [illegible] e the effect of putting an [illegible] ncreasing fraud not only on professional men but on the public.

We are, Sirs, yours faithfully,
HERBERT WILLIAMS,
President.
A. W. W. BAKER, M.D. Dub., F.R.C.S.I.,
Past President Irish Branch B D.A.
GEO. M. P. MURRAY, F.R.C.S.I.,
Past President Irish Branch B D.A.
KEVIN E O'DUFFY,
Honorary Secretary.
Dublin, March 3rd, 1904.

⁂ The decision of the King's Bench Division in Dublin is exceedingly to be regretted, particularly as further appeal in the Irish courts is impossible.—ED. L.

PREVENTION OF INFECTIOUS DISEASE IN BATH.

To the Editors of THE LANCET.

SIRS,—The notes under the above heading from your Wales and Western Counties correspondent in THE LANCET of Feb. 27th, p. 614, seem likely to give a wrong impression of the relations existing between the medical officer of health and the sanitary committee of this city. As I am the councillor to whom allusion is made I hope you will allow me space for a few remarks.

In the first place, I should like to say that the committee as a whole, and especially I myself, fully recognise that in Dr. W. H. Symons we have got a most efficient and energetic medical officer of health. Sometimes, however, his energy and anxiety for the city's welfare seem to outrun his discretion, and this, it appeared to me, was so in the case especially alluded to by your correspondent. I inclose you two notices lately sent out by Dr. Symons. In the one dealing with measles and whooping cough I took exception to the paragraph on the first page which speaks of a penalty of £5 to which a person is liable for exposing himself while infected in the streets. Your correspondent says I "expressed the opinion that Section 126" of the Public Health Act of 1875 "only applied to those diseases which were scheduled" and not to measles and whooping-cough. I would point out to him that this is not a question of *opinion* at all; it is simply a matter of fact: the section does only apply to scheduled diseases. At a subsequent meeting to that referred to, I offered to support Dr. Symons if he wished to have measles and whooping-cough included in the schedule. While, however, he did not advise our doing this, he was still of opinion that the clause, which I claimed was misleading to the public, should be retained since, among other reasons, "it was done elsewhere." Two cases had recently come to my knowledge in one of which the mother of a child suffering from whooping-cough was afraid of bringing her child to the hospital for treatment; and in the other was afraid of going out to earn her living because of the penalties to which she thought, from reading this notice, she was rendering herself liable.

The other notice I inclose you was sent to all the medical men practising here. In it you will see we are reminded that it is *illegal* to remove patients suffering from notifiable diseases in public carriages, although Section 127 of the Public Health Act especially provides for what is to be done in the event of patients being so removed. That it is most undesirable for public carriages to be used for this purpose everyone will allow, and luckily here in Bath with our ambulance accommodation it is not necessary, but why tell the profession that what an Act of Parliament especially provides for is illegal? As I said at the beginning I have great respect for Dr. Symons's energy and ability, but I cannot support him in the issue of notices that are incorrect and misleading, simply from a mistaken desire of doing good thereby. "Bluff" may succeed in other matters, but it is neither politic nor dignified in the administrator of public health.

As to the bacteriological examination in suspected diphtheria, to which your correspondent also alludes, seeing that in this case the reporter had found Hoffmann's bacilli, which he especially said were not regarded by the "Cambridge school" as pathogenic, I said that, whilst not wishing to hamper Dr. Symons in any way, I hoped he would use discretion in sending cases for examination. I am entirely at variance with your correspondent as to excluding the press from the ordinary meetings of the committee. The health of our city is so good that we have nothing to keep dark, but if his advice were followed there would not be the same public confidence that this was so.

I am, Sirs, yours faithfully,
Bath, Feb. 29th, 1904. PRESTON KING, M.D. Cantab.

EYESTRAIN AND ITS REFLEXES DEPENDENT UPON LOW ERRORS OF REFRACTION.

To the Editors of THE LANCET.

SIRS,—Will you pardon me a few words of reply to your courteous editorial concerning eyestrain, in your issue of Feb. 6th, just at hand? The essential point in the controversy is entirely omitted by your writer and this is that the low errors of refraction are the cause of the reflex troubles which you think I exaggerate as due to eyestrain. This I have emphasised all through my writings and prove every day in private practice. And not only myself but hundreds of other American oculists. The very condition of success in curing these patients is, we contend, the very thing you frankly ignore. There is no more clearly demonstrated fallacy, no greater scientific error than that exhibited in your own quotation from Donders as to the unimportance of errors of less than a dioptre. These small errors of astigmatism are the causes of the troubles of the patients, reports of whose cases I have published, and of thousands in private practice. The statements as to the care and accuracy of most English and continental ophthalmologists are erroneous and the editorial demonstrates this. The low errors, the low degrees of unsymmetric astigmatism which cause migraine, are ignored in the editorial which is, you say, made up from the opinions of London oculists. It is a perfectly simple matter to demonstrate the truth of my contention. A good oculist by correcting the low errors (those below a dioptre) will cure many or most of the migrainous patients excluded from your oculists' offices by "a clean bill of health" as regards their eyes. Conversely, if those who give the clean bill of health will wear a pair of spectacles *producing* artificially such low errors of astigmatism they will have a most convincing migraine very speedily. It is *not* fair to my argument to ignore entirely the low error of refraction which repeatedly, emphatically, and continuously I have said is the cause of the sufferings *due to* ocular conditions. Nor does it seem fair not to present another fundamental argument of both volumes of my "Biographic Clinics": the fact that every one of the 14 patients whose histories are there described suffered because of *near* use of his eyes, and got immediate relief only by stopping reading and writing, when exercising out of doors, &c. A thousand quotations demonstrate this fact. Can it be explained on any other theory than eyestrain? Why is there such a strange disinclination of reviewers, critics, and editorial writers to mention this fact which is the substance of the mass of quotations of both books?

Respectfully yours,
GEORGE M. GOULD.
Philadelphia, Pa., U S A, Feb 23rd, 1904.

⁂ We publish Dr. Gould's letter with pleasure, but we remain of the same opinion. It is not correct to suggest that our ophthalmologists are ignorant of the possible constitutional trouble that will follow slight errors of refraction; while we are certain that the results of these errors have been exaggerated.—ED. L.

BILHARZIA HÆMATOBIA.

To the Editors of THE LANCET.

SIRS,—In reply to Mr. E. H Worth I desire to state that a patient of mine who is suffering from this disease contracted it in the Komati Poort Valley of the Transvaal, where he was severely wounded in the disaster to Colonel Benson's column. Whilst in the military hospital he tells me that he took (?) a solution of boric acid, but said "that he always felt worse afterwards and lost more blood." I have found that his hæmaturia has almost disappeared, the lumbar pain has been banished, and his health proportionately improved whilst he has been taking the following: one drachm of sodium salicylate, two drachms of compound tincture of gentian, one drachm of tincture of strophanthus, two drachms of chloric ether, and infusion of buchu to one ounce.

I am, Sirs, yours faithfully,

PERCY RENDALL, M.D.

Ewell, Surrey, March 2nd, 1904.

THE BATTLE OF THE CLUBS AT SOUTHAMPTON.

To the Editors of THE LANCET.

SIRS,—With reference to the article in THE LANCET of Feb. 13th respecting the battle of clubs in Southampton I beg to say that it is a tissue of false and erroneous statements all the way through. Your informant is evidently very ignorant of what he is writing about. In the first place, he states that the Dock Provident Society *imported* a medical man. This is untrue, as I had taken a house in Southampton before I knew of the existence of the society and it was some days after that I saw the advertisement for a surgeon in the local paper. I replied to this and was duly elected by the committee. As to the society being the means of founding the Medical Federation in the town, this is false, as the society has nothing to do with the federation and never had. So far from not having sufficient work to do I may say that I had a very busy year as this being one of the oldest registered societies in the town it led up to many others, and I may say that with a very few exceptions I have met with nothing but expressions of gratitude and many acts of kindness from all the members. With regard to the London and Manchester and the National Medical Aid I have never had anything to do with them. I believe the latter society was bought up by one of the medical officers of the federation. With regard to the female O. F. they pay the same rate as the males; if it pays the medical officer for one why not for the other? They are all young women and seldom trouble one. From what I hear many of the medical men who stuck out for 6*s.* 6*d.* are now offering to take them for 5*s.* per annum *if they can get them.* It appears to me these men have acted like a set of schoolboys instead of business men. The federation is an amalgamation of various clubs, is exceedingly well managed, and is rapidly increasing in numbers. I inclose a cutting from the local paper respecting the club question. The Southampton Provident Medical Association has attacked the smaller clubs but is afraid to attack the larger societies, which in my opinion shows its weakness. The numbers which your correspondent states have joined the association are not correct.

I am, Sirs, yours faithfully,

ARTHUR GRAHAM,
Surgeon to the Dock Provident Society; Surgeon to the Medical Federation, Southampton.

Southampton, Feb. 23rd, 1904.

PS.—I wish to state that I have always been opposed to well-to-do tradespeople deriving benefit from these clubs.

⁂ We were informed that Mr. Graham applied for the post under the Dock Provident Society from an address in London, which certainly pointed to importation. He has since told us that he had already arranged to take a house in Southampton before receiving the appointment, a circumstance which alters the position. Our information does not bear out his statements that the Dock Provident Society has nothing to do with the federation and that the federation is rapidly increasing in numbers. With regard to the number of adherents to the Southampton Provident Medical Association the figures were obtained from a source that ought to be trustworthy and a general statement that they are not correct does not impress us. Our correspondent must point out the error in detail when, if he is right, we shall be happy to say so.—ED. L.

MISTLETOE.

To the Editors of THE LANCET.

SIRS,—It has occurred to me that the following note may be of interest to your readers in connexion with the annotation on the subject of mistletoe which appeared in THE LANCET of Jan. 9th, p. 111. The substance of the note is translated from a well-known work in Persian on Materia Medica, the *Makhzanu l-Adwiya* (Storehouse of Medicines), compiled by one Muhammad Husain Khān in the year 1185 of the Hijra, corresponding to 1771 A.D. His statements concerning the mistletoe may be regarded as embodying the opinions of all the oriental authorities up to the date of his work. It will be seen that mistletoe was looked upon as injurious to the heart rather than beneficial. The author writes as follows:—

"*Dibq,*[1] called also *qusūs*, and in Persian *Mawizak-i-'Asah'* (the honey-creeper) and *Kishmish i-káwaliyá* (the Cábuli raisin), is a berry smaller than the chick-pea, of a greenish colour, and when it dries its skin shrivels and turns black. It contains in its interior a glutinous moisture and the seeds are of the size of poppy seeds. The plant grows on the pear and other trees, several twigs shooting from one point. The leaves resemble somewhat those of the múrd[2] and the pomegranate; they are delicate in texture and greyish green. The best kind when fresh are smooth and round. Their colour inside is like that of the leek and the outside inclining to greenness, blackness, and redness. Their constitution is hot in the extreme of the second degree and dry in the first degree, possessing an excess of moisture which is not glutinous. Certain authorities consider it hot and dry in the third degree. Its properties are compounded of the essence of aerial heat and aqueous coolness, with a slight admixture of earthy astringency, and after being ingested by anyone its special effects are (speedily) manifested.

Its special action and properties.—It is attenuant, discutient, and laxative—efficacious in dispersing thin and gross humours and absorbing them from the depths of the body. When it is macerated in warm water and the skin and seed are separated from the juice by squeezing, and the pure juice mixed with the kernels of the walnut or with the pulp of the fruit of the *Bidanjīr*[3] (which is the usual way of drinking it), it is effectual in purging away the black bile and mucous humours; also useful as a deobstruent and in sciatica, fistulous sinuses, and cold abscesses. An ointment compounded with it ripens and melts down and collects the matter in swellings and allays cold pains, while with turpentine and wax it is used for the ripening of boils, pustular eruptions of mucous origin, and phlegmatic tumours, also for softening the joints. Mixed with *zarnīkh*[4] it is also used for the last three purposes and with gummastich it is used for malignant ulcers and with arsenic and pitch it is used to extract the nails. With quicklime and grape juice and honey it is used to make the nails grow again. With henna[5] it is used in the treatment of impetigo and dandruff, also with oil of roses for making the hair grow long. A decoction of it in lime water is useful in removing swellings of the spleen, while a paste of it made with lime is a means of removing induration of the spleen and is also useful in drawing out gross humours from the depths of the body. It is injurious to the heart, the corrector of this influence being the *Bādranjbūyah.*[6]

The quantity to be taken [? of this decoction] is up to one *misqāl*[7]; a larger quantity causes gripes and vertigo with heaviness of the limbs. In lieu of it, as an equivalent in discutient power, is half its weight of juniper berries and four *dángs*[8] of almonds, and in all cases half its weight of *Agir karhā.*[9] When mistletoe berries are cooked with honey, syrup of dates, and *sapistán*,[10] and made into long fine threads, it is put on the surface of trees, when any bird that settles sticks to the tree and is caught. When it is mixed with *Qirmuz*[11] it intensifies its (crimson) colour. It forms an ingredient also in many other colours."

With apologies for the length of this note,

I am, Sirs, yours faithfully,

GEORGE RANKING, M.D. Cantab.,
Lieutenant-Colonel, I.M.S.

Calcutta, Feb. 6th, 1904.

---

[1] Viscum album.

[2] Múrd, Myrica Gale.

[3] Ricinus communis.

[4] Zarnīkh is the name for arsenic (= azzarnīkh) in all its forms. It is probably yellow orpiment which is here intended to be used.

[5] Lawsonia inermis.

[6] There is a little uncertainty as to what is meant by this name. By Abdullah Shírází, court physician to the Emperor Sháhjehán. it is said to be the sweet basil, called in Hindī Julsī (Ocymum sanctum). That author also includes it in his list of cardiac tonics (Alfázi Adwiyah).

[7] The *misqāl* was equivalent to 96 barleycorns in weight.

[8] The *dáng* was equivalent to 16 barleycorns in weight.

[9] Agirgarhá, Anthemis pyrethrum.

[10] The fruit of cordia myxæ (cordia sebestana).

[11] Kermes, coccus baphica.

THE IRISH MEDICAL DEGREE PRIOR TO 1858.

To the Editors of THE LANCET.

SIRS,—In a book lately published by Mr. R. Brudenell Carter entitled "Doctors and Their Work," the following statement occurs (p. 8): "While such was the state of things in England (i.e., prior to the Medical Act of 1858) it had been from time immemorial the custom of Scottish and Irish universities to confer degrees in medicine after examinations which were mainly medical in their scope, and which could not be held to establish more than a modest amount of acquirement in scholarship or general knowledge. In these divisions of the Kingdom, therefore, the degree and title of 'Dr.,' instead of being confined to the highest grade of the profession, belonged of right to the great body of general [illegible] ntially different [illegible]"

As far as Ireland is concerned nothing could be more remote from the truth. The University of Trinity College, which up to 1852 was the only university in Ireland, has [illegible] nemo admittatur qui prius Baccalaureatum in Artibus non susceperit." Not only so, but of all British universities Trinity College is (with the comparatively unimportant exception of Oxford) the only one all of whose graduates in medicine are also of necessity graduates in arts. It is true that at the time of which Mr. Carter speaks there were many general practitioners and apothecaries in Dublin styling themselves "Dr.," but they invariably had Scottish qualifications. Mr. Carter has promised to correct the error should his book reach a second edition.

I am, Sirs, yours faithfully,
T. K. ABBOTT,
Senior Fellow and Senior Proctor, Trinity College, Dublin.

OPIUM AND PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—I was much interested in your leader in a late number on the subject of "Opium and Pneumonia" because I have been convinced for the past 15 years that that drug has a deal to answer for in the mortality from the disease. Let us consider what is the condition at the moment of crisis of that grave disorder. The lung is occluded with a thick tenacious slime almost impossible to throw off. The right heart is battling to get the blood through this occluded lung. And what is done by giving opium or any of its derivatives? The tenacity and thickness of the slime is increased and at the same time the heart's power is enfeebled and bewildered, also that of the respiratory centre. Could any therapeutic power be less well directed? We enfeeble and shackle the cardiac and respiratory powers at the very time their utmost strength is required and at the same time add to the obstructive power, the tenacity and dryness of the slime Surely this is clear, but what is the excuse for such a mode of treatment? Oh, it dulls and stills pain and restlessness and the patient "feels better." Better? Yes. Euthanasia! The necessary pain and restlessness must not be dulled; they are requisite for recovery. *Excessive* pain may be relieved by other means—a few leeches, an ice bag, &c., or even a minute hypodermic dose of morphia not sufficient to have a constitutional effect. Aconite, too, is a most dangerous drug in pneumonia, given to "lower the temperature." But, alas, it paralyses the cardiac centre. Such drugs as digitalis and strychnine must also be given with great discretion, for though they may increase the cardiac power it must be remembered that they also increase the muscular tone of the arteries and therefore resistance to that power.

Now it is universally admitted that pneumonia is due to a microbe and its toxins. It appears to me that treatment should be directed to the destruction of that microbe and its effects and that symptomatic treatment should be entirely secondary. With that view I have now for many years prescribed salicylate of soda with liquor ammoniæ acetatis and in suitable cases (threatened heart failure) spiritus ammoniæ aromaticus. The salicylate not only helps to arrest the rapid multiplication of microbes but it rapidly throws off the toxic products through the kidneys. The acetate of ammonia not only counteracts any cardiac depression (though I have never noticed any as especially due to the salicylate) but also liquefies and loosens the thick "slime" in the lung and makes it the more easy to expectorate it. If we cannot be sure we are giving the right drug let us stand aside. Nature alone will do better than we. Let us be sure we do not add the last straw to the burden in the terrible crisis.

Influenced by these views I have in later years only used the drugs I have mentioned in this dire disorder and the result has been that I have never lost a case. I have had most serious cases, one in delirium tremens where another medical authority thought there was no hope, but the patient rapidly got well. Within the last few months I have had two cases of pleuro-pneumonia in aged people the results of which are striking. The one, aged 69 years, a very healthy life previously, declined to take the salicylate, as he said it made him feel sick. He recovered from the immediate attack but developed an empyema which, after repeated aspirations (the pneumococcus abundant in every specimen of the pus), killed him by developing complications elsewhere (operation was declined). The other, aged 76 years, an equally severe attack, took the salicylates readily, had a copious serous effusion in the pleura, but has recovered completely.—I am, Sirs, yours faithfully,

Lancaster, March 6th, 1904. C. A. RAYNE, M D. Lond., &c.

THE SETON IN MÉNIÈRE'S DISEASE.

To the Editors of THE LANCET.

SIRS,—Referring to Dr. T. Wilson Parry's very interesting communication, may I be permitted to point out that I described a case of Ménière's disease successfully treated by the seton in the *British Medical Journal* of March 29th, 1902, p. 806? It was suggested to me by Mr. Walter Whitehead's remarkable success in the treatment of migraine. I am, Sirs, yours faithfully,

Southport, March 8th, 1904. COLIN CAMPBELL.

THE ADULTERATION OF COD-LIVER OIL.

To the Editors of THE LANCET.

SIRS,—I am perfectly in agreement with Mr. E. J. Parry in his contention that the value of cod liver oil is due to the facility with which it is digested and absorbed and not to any active principle. In this sense his use of the word "traditional" is justified and therefore possibly other fats have not had their fair share of consideration. Virol, to which he refers, the fatty portion of which is chiefly supplied by bone-marrow, is a substance which we have largely used at the Children's Hospital here with excellent results, young children taking it with facility and advantage. Possibly it would be well, remembering how scarce and expensive cod-liver oil has become, if we were to investigate the whole subject of the value of the various available animal fats *de novo* and determine their relative advantages on their merits alone, eliminating any element of tradition.

I am, Sirs, yours faithfully,
L. A. PARRY, M.D. Lond., F.R.C.S. Eng.

Hove, Sussex, March 8th, 1904.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Vaccination amongst Ancient Hindus.—Increase of Plague.

A POINT of immense historical interest has lately been referred to by a writer in the *Madras Mail* It practically consists in the discovery that vaccination as we know it, and not merely inoculation for small-pox, was practised in ancient Hindu days. In the "Sactaya Grantham," an ancient treatise attributed to Dhanwantri, the writer after describing nine species of small-pox lays down rules for the practice of inoculation (? vaccination). The translation of the passage is as follows: "Take the fluid of the pock on the udder of a cow or on the arm between the shoulder and elbow of a human subject on the point of a lancet and lance with it the arms between the shoulders and elbow until the blood appears; then mixing the fluid with the blood the fever of the small pox will be produced." Again, "The small-pox produced by the fluid from the udder of a cow will be of the same gentle nature as the original disease, not attended by fear, not requiring medicine; the diet may be according to the pleasure ot the patient who may be inoculated once only or two, three, four, five, or six times. The pock when perfect should be of a good colour, filled with a clear liquid and surrounded by a circle of red; there will be no fear of the small-pox as long as life endures. When inoculated with the fluid from the udder of a cow some will have a slight fever for one, two, or three days, and with the fever there will sometimes be a slight cold fit; the fever will also be attended by a round swelling in the armpits and the other symptoms of small-pox but all of a very mild nature. There will be no danger and the whole will disappear in three days." These extracts are taken from the *Madras Courier* of Jan. 12th, 1819. Maclean, in the Manual of Administration, referring to Dhanwantri, says that Sanskrit treatises on medicine bear his name and I am also informed that there is a Tamil medical work which has been printed known as Dhanwantri Cauvyam and which is a treatise on Hindu medicine. I have not yet been able to verify these quotations but the writer in the *Madras Mail* has kindly furnished me with the above references and translations.

The plague epidemic is steadily increasing with ominous signs in certain districts. In Central India the deaths are over 1000 a week, whereas last year they were numbered in tens. In the United Provinces the plague mortality is nearly double that of last year and there is a marked increase also in the Punjab. The disease seems to be declining in the Bombay districts but is developing rapidly in Bombay city. A recrudescence is also showing itself in Calcutta.

Feb. 18th.

CHOLERA IN THE TURKISH EMPIRE.

(FROM THE BRITISH DELEGATE ON THE OTTOMAN BOARD OF HEALTH.)

SINCE the date of my last letter on this subject (which appeared in THE LANCET of Jan. 23rd, p. 255) cholera has not been very active in any part of the Turkish empire. The infection has, however, reached the important town of Basra, at a short distance from the head of the Persian Gulf, and occasional cases are—or were till quite recently—reported from Syria. It is clear, therefore, that the cholera infection is still present over a very wide area, though showing no great intensity in any part of that area.

In Bagdad the disease appears to have died out, as no case has been reported from there since Jan. 7th. The same statement holds for Kerbela, where no case has been observed since Jan 12th. The extent of the outbreaks in these places will probably never be known. The sanitary officer of Bagdad states that there, and still more in Kerbela, a large number of cases occurred which never came to the knowledge of the authorities. In Kerbela he thinks the cases were at least double those reported officially. In Diarbekir the last known case occurred on Jan 9th and in Mossoul on Jan. 6th. At Hindieh, near Kerbela, it was reported as late as Jan. 30th by a medical officer who had just visited the place that cases were probably occurring among the nomad tribes in the neighbourhood without their coming to the knowledge of the authorities.

The outbreak at Basra seems to have begun on Feb. 6th though the cases were not seen by the sanitary officer until the 8th. On the latter date he telegraphed that he had seen two women and a child, inhabiting different houses and different quarters of the town, all of whom had fallen ill on the 6th and all presenting the symptoms of cholera. The source of infection in these cases has not been determined. The further course of the disease here has been as follows From Feb. 6th to 12th there were seven cases with four deaths, from the 13th to the 20th there were six cases with six deaths, and from the 21st to the 28th there have been as many as 13 cases with 19 deaths. The least satisfactory feature in the later reports has been the fact that so many of the cases have only been discovered after death. On Feb. 9th the Board of Health imposed five days' quarantine on arrivals from Basra. For persons ascending the river from Basra to Bagdad a temporary lazaret was established at Kermet-Ali, a place about two hours' distance from Basra. On the 17th a case of cholera was observed among the passengers of the s.s. *Mossoul* which had arrived at the lazaret from Basra on the 15th. The patient died in the lazaret two days later. On the 20th another case developed among the passengers of the same ship and a third case among the crew of a sailing ship undergoing quarantine. A fourth case was observed in the lazaret on the 21st. All of these cases ended fatally. Up to the 28th the total cases of cholera in the town of Basra and the lazaret of Kermet-Ali together have been 30 and the deaths 33.

To-day news has been received of the occurrence of a "suspected" case of the disease at Korna, a village at the junction of the Tigris and Euphrates. No details of this case have as yet been made known.

In the Aleppo vilayet cholera has been almost, though not quite, extinct during the months of January and February. It will be recalled that a single case of the disease was observed in Aleppo itself on Jan. 5th. Another was reported on the 24th of the same month. No other case has been since reported. At Aintab, to the north of Aleppo, a fatal case was observed on Jan. 19th. Both of these cases (in Aleppo and Aintab) were spoken of as "suspected" only, but all measures were taken as for undoubted cholera cases.

In the Syria vilayet no cases of cholera have been officially reported since the beginning of the year, but on the first day of the year news was received of the appearance of the disease at Nibe and at Inebe, two places in the district of the Hauran. Mention must also be made of a "suspected" case at Latakia on Jan. 3rd. The Hauran district suffered considerably from cholera last year. Whether the disease is still active there or not it is impossible to say as no definite news has been received from there since Jan. 1st, but it is to be noted that in successive reports from the medical officer on special mission at Damascus it is stated that news from the Hauran, and particularly from the Ajloun district, is "far from precise" or "disquieting" or that the presence of cholera is rumoured there.

The total number of cases of cholera in the Turkish empire from March of last year to Feb. 22nd of this year is put down at 7652 and of deaths at 6550. The estimate I made in my last letter as to the extent to which the official totals may be believed to differ from the actual totals has been thought by many to be far too moderate. Some would place the true figures at double or even treble the reported figures.

Constantinople, Feb. 29th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Health Committee.

AT the last meeting of the city council the resignation of Mr. John Parker, inspector of nuisances, was received and accepted. Mr. Parker had been in the service of the corporation for a period of 22 years, first as an assistant inspector and since 1885 as inspector; he has always been a most active officer and great regret was expressed that the committee was losing his services. On the recommendation of the health committee, which advised that in a city of the size of Birmingham there was need for the services of an assistant medical officer of health, the council created that post and appointed thereto Dr. J. Doig McCrindle. This gentleman was also appointed inspector of nuisances of the city at a salary of £300 per annum. Dr. McCrindle has been in the service of the health department since June, 1902, first as medical superintendent of the small-pox hospital and recently, since the decline of the disease, he has been assisting the medical officer of health. In his new appointment he will be responsible for all measures taken for the prevention of infectious diseases and will have charge of the disinfecting staff and apparatus. The milk-shop inspector, the lodging-house inspectors (two men), and the canal-boat inspector will also be under his charge. Mr. Frank Thompson, who has acted as chief inspector of nuisances since 1898, has now been appointed inspector of nuisances and will be responsible for all matters relating thereto, such as the conversion of pan-privies into water-closets, the repair of defective drains, yards, &c He will have under his charge the 19 district inspectors, four smoke inspectors, and the court cleaners. The health committee has advised the council that, in addition to the two male inspectors who carry out duties under the Factory and Workshops Act, 1901, there ought to be a woman inspector whose duty it should be to supervise the workshops in Birmingham where female labour is employed. There are over 10,000 workshops and workplaces in Birmingham, including a large number of places where food is prepared for sale, and in addition to these there is a large number of shops which require occasional inspection under the Shop Hours Acts and the Seats for Shop Assistants Act. During the past year 1927 cases of chicken-pox were notified at a cost to the city of about £230. The object of adding chicken-pox to the list of notifiable diseases was to enable any doubtful cases to be visited immediately by the medical superintendent of the small-pox hospital. In practice, however, it has been found necessary to visit only those cases to which the medical men directed special attention as being doubtful. On the recommendation of the committee the order for notification of chicken-pox has been rescinded and it is to be left to medical practitioners to call the attention of the health department, as they are now doing, to any case in which they would like the diagnosis verified. Alderman Cook, in moving the adoption of the recommendations of the committee, stated that small pox had passed away from the city and that the small-pox hospital was entirely empty. It had not been absolutely closed because there were still cases at Leicester and other places not far from Birmingham, and they might any day have a case in the city, but they were only retaining the staff necessary for keeping the hospital in proper order. The members of the committee had had an anxious time with regard to the disease but they claimed that they had been successful in preventing it spreading. As a rule the cases appeared in tramps found in lodging houses or the workhouse and they were still seeing that every supervision was exercised so that they might deal with the first case that made its appearance. The council would see how infinitely important this supervision was when he told them that during the past year their inspectors found no fewer than 28 persons in lodging houses who on medical examination were proved to have small-pox.

Rural Depopulation.

Mr. A. Lane, of Broom Court, a well-known Warwickshire farmer, has issued a new scheme for the formation of an association to prevent the migration of so many of the agricultural labourers to the towns. His idea is that an association should be formed connected with the Bidford Flower Show and Sports, to provide for young men, who have hitherto earned their wages on the land for a certain number of years, a bounty when they marry and settle down in the district. The scheme was discussed at a meeting of subscribers to the flower show. The ideal to which Mr. Lane aspired was a cottage occupied by a young and healthy couple, with a garden attached to be well stocked with vegetables and fruits. He suggested that members should pay, perhaps, 2*s.* a year for a period of five years and in return should receive a sum of £10 towards furnishing a cottage when they desired to marry. He thought that it would be a great advantage to the district as it would encourage labour, especially in the growing of fruit and vegetables. There was a difficulty about the providing of cottages, but he thought that the landlords would be encouraged to help in this if they saw the labourers doing their part to make the scheme work. He suggested, too, that the Government might grant loans to the owners of land for the purpose of building cottages. He proposed that the subscribers to the show should form themselves into an association for the purpose of helping young men who had already worked on the land and were desirous of settling there. The scheme was also advocated by the Rev. R. P. Ridsdall. Mr. G. H. Fosbroke, medical officer of health of Worcestershire, said that he was going to give evidence before the Commission on Physical Deterioration and his evidence would be to the effect that the labourers must have greater facilities and the power and opportunity to become actual owners of land and houses. The Worcestershire county council had put the Small Holdings Act of 1902 into force with great success and he asked why the same could not be done in Warwickshire. He suggested that the Warwickshire county council should be approached to assist labourers to acquire land and to build houses. He feared that Mr. Lane's proposal would not give the labourers sufficient interest to remain in the country and landlords could not build houses now except at a loss. A committee was appointed to consider Mr. Lane's scheme and to report to a future meeting.

The Dean of Worcester on Vivisection.

The Dean of Worcester recently presided at the annual meeting of the Worcester branch of the Society for the Prevention of Cruelty to Animals. The report recorded a prosperous year's work and that the society was in a flourishing condition. The committee felt very strongly on the subject of vivisection that no case should ever be performed by any but licensed and experienced professors and always under the influence of an anæsthetic and that the animal should be destroyed immediately afterwards. The Dean expressed his agreement with the views of the committee on the subject of vivisection. He had recently been asked to sign a petition and to speak in Birmingham against vivisection but had declined to do so as he believed in it. He thought that there was a good deal of ignorance in the public mind as to such experiments; cruelty was not permitted by the regulations and people should remember the benefits conferred on the human race by vivisection. He protested against the caging of singing birds and the destruction of larks to make a dish and of other birds solely for the purpose of ornamentation. Canon Cresswell Strange expressed his dissent from the opinions of the Dean on the subject of vivisection, to which the Dean replied that if the society was opposed to his views on this subject he should feel compelled to withdraw from the presidency.

Birmingham Sanatorium.

The Lord Mayor presided at the thirty eighth annual meeting of the subscribers to the Birmingham and Midland Counties Sanatorium held recently. In its annual report the committee announced that it had received a draft order from the Charity Commissioners approving the scheme [illegible]am by the aid of Colonel J. H. [illegible] the property at Sutton Coldfield. [illegible] be commenced as soon as the [illegible]anged. The alterations comprise the removal of the present kitchen and the erection in its place of a handsome dining hall capable of seating 110 patients; also of a new kitchen, servants' sitting room, larder, and scullery on a portion of the yard adjoining the building and an additional dormitory over each wing of the original structure. The system of drainage is to be remodelled. It was estimated that the alterations would absorb the whole of the proceeds of the property at Sutton Coldfield. The statistical tables for the year showed a slight falling off in the number of patients admitted, there being 1418 in 1903, against 1482 in 1902, while the number of days' stay was 25,592, compared with 26,867 in the previous year. The average stay was nearly one day longer. The average number of patients in the institution was 70·1, against 73 5. The difference arose partly from the decision of the committee not to admit consumptive patients and partly from the smaller number of special tickets purchased by the committee of the Hospital Sunday Fund and by the trustees of the Ronakes Charity. The total of the subscriptions was £1825 15*s.*, as compared with £1908 8*s.* 9*d.*, and the subscriptions carried forward amounted to £998 17*s.* 6*d.*, against £1031 8*s* 6*d.* The cost of maintenance remained the same as in previous years, but the yearly expenses per bed had increased by £2 11*s* This increase was attributable to the special expenditure in fire appliances and to the cost of renovating the whole of the mattresses.

March 9th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. John Thomson.

BY the death after a short illness of Mr. John Thomson, chairman of the Manchester Royal Infirmary board, Manchester has lost one of her most valuable citizens. For a long period he was a member of the old infirmary board but on the long debated question of the removal or of the rebuilding of the infirmary on the Piccadilly site he favoured the removal. When the trustees at a meeting in 1902 decided to rebuild on the Stanley-grove site the greater number, including the much respected chairman, Mr. Edward Heywood, resigned their seats and Mr. Thomson was elected chairman of the new board. From that time to the date of his fatal illness he rendered invaluable service to the institution. His conciliatory bearing, the outcome in his case of genuine kindness of heart, combined with his great business capacity, was most helpful in overcoming difficulties and smoothing down differences. The loss of him will long be felt. One of the honorary staff said the other day that it was irreparable and another spoke warmly of the great interest which he showed in the medical school and also in the students over whom his influence was all that was good. He was a member of many of the important commercial institutions of the city and as chairman of the Bankers' Institute he advocated the establishment of a faculty of commerce at the Owens College. In 1901 he was president of the Chamber of Commerce. He was, moreover, actively interested in most of the philanthropic work in the city and for over 25 years he left his pleasant home at Bowdon every Sunday and Wednesday to conduct a Bible class in Hulme. He was a Liberal but did not take any very active part in politics till the last few years, and last autumn he was chosen as the Liberal candidate for one of the divisions of Manchester. He was broad-minded and tolerant and his friendships were not narrowed by his politics. As regards recreation he was fond of outdoor sports, was a good shot, and a capital angler. His funeral was marked by indications of widespread respect and regard.

Manchester Royal Infirmary.

The infirmary board held a special meeting yesterday to receive the report of Mr. J. J. Burnet of Glasgow, the assessor appointed to consider the plans for the new infirmary in Stanley-grove. 12 firms of architects were invited to prepare plans and those selected were found to be the work of Mr. Edwin T. Hall and Mr. John Brooke of London and Manchester, who were yesterday appointed by the board the architects for the building of the new infirmary. The surveyor of the board reports that the plans will entail an expenditure of £324,000, with an additional £16,500 if the full 600 beds are provided. All the designs submitted to the assessor will be exhibited in the course of the next few weeks at the City Art Gallery. The board reserves the right to alter or to vary the plans and before they are finally approved a meeting of the trustees must be held for the purpose of endorsing the action of the board.

Cremation for Paupers.

At the meeting of the Manchester board of guardians on March 2nd the question of cremation for paupers, which had been before it previously, was again referred to. At the previous meeting it was decided that the cost (£5) would be too great. A letter was read by the clerk stating that the directors of the crematorium "were willing to take into consideration the cremation of paupers at a cost of somewhere about 10*s*. each, which would include the use of the crematorium chapel, the decoration of the same with plants, and the use of the pall." On sanitary grounds no doubt cremation is unobjectionable, if not, indeed, distinctly desirable, and one gentleman thought that it should be carefully considered both on sanitary and economical grounds but that it could be carried out only when there were no relatives to claim the bodies. Another said that they ought to have some regard for the sentiment of the poor for there were many to whom cremation would be repugnant. There is no reason to fear that the Manchester guardians will deal harshly in the matter.

Anthrax in Manchester.

On Saturday last, March 5th, a man was admitted to the Manchester Infirmary from Levenshulme suffering from anthrax. It was supposed that he had been inoculated (in the arm) from a beast which he had killed. While arrangements were being made for his removal to the Monsall Hospital, for it was not a case to be kept at the infirmary, he left the building and does not appear to have been traced. Yesterday a young man from Sandbach was admitted also suffering from anthrax and it came out that he had dressed the beast which the first man had killed. He was at once sent to the Monsall Hospital.

March 8th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Cardiff.

A CASE of small-pox was reported in Cardiff on March 1st, the patient being a dock labourer. The whole of Wales has been singularly free from the disease for many months. In Cardiff during the second quarter of 1903 there were 45 cases notified and two deaths occurred, both of persons over 25 years of age. In the second half of the year not a single case came under the notice of the medical officer of health.

Death of Mr. Denis Nyhan, L.R.C.P. & S. Edin., L.F.P.S. Glasg.

Through the death of Mr. Denis Nyhan on March 1st at the early age of 32 years a very promising career has been cut short. He succumbed to an attack of pneumonia after an illness lasting only five days. He was a native of co. Cork and received his medical education at Queen's College, Cork, taking his diplomas at Edinburgh and Glasgow in 1897 and almost immediately settling in Brynmawr, Breconshire, where at the time of his death he held the positions of medical officer of health and certifying factory surgeon.

Tredegar Health Report.

In the annual review for the year 1902 of the sanitary condition of the county of Monmouth the sanitary committee of the county council animadverted upon the condition of Tredegar, the criticisms apparently having reference to the high death-rate—22 9 per 1000—and to the prevalence of typhoid fever. The annual report of the medical officer of health of Tredegar (Mr. G. A. Brown), which has been recently issued, shows that very different conditions prevailed in 1903 when the adjusted death rate from all causes was only 17 per 1000 or lower than any death-rate recorded in the district during the previous ten years and there were only 11 cases of typhoid fever notified compared with 42 in 1902, while a still more satisfactory feature of the report is to be found in the decreased rate of infantile mortality which in 1903 was 127 per 1000 births compared with an average rate in the previous ten years of 160 per 1000. This result is in some degree, no doubt, due to the excessive amount of rain which fell, the rainfall for the year having been 83 inches, whereas the average for the preceding 22 years was 58 inches. The district is not well sewered and the river which flows through it, though at times a raging torrent, is sometimes a mere brook and little better than a stagnant sewer.

The Recent County Council Elections in the West of England and South Wales.

Mr. John Meredith, M.D. Edin., has been returned for the Wellington district of the Somerset county council. Mr. E. J. Parry, M.D. R U.I., has been returned for the Garw Valley district of the Glamorganshire county council. Mr. R. L. Thomas, L.S.A., has been returned for the St. Clears district of the Carmarthenshire county council. Mr. Howell T. Evans, M.R.C.S. Eng., D.P.H. Cantab., has been returned for the Bedwellty district of the Monmouthshire county council. Mr. W. Dyne Steel, M.D., C.M. Aberd., has been returned for the Abergavenny district of the Monmouthshire county council. Mr. T. Hall Redwood, M.D., M.S. Durh., has been returned for the Rhymney district of the Monmouthshire county council.

Health of Torquay.

The medical officer of health of Torquay (Dr. T. Dunlop) in his annual report for 1903 states that the area of the borough is 3858 acres, the estimated population being 33,800. The crude death-rate was 13·4 per 1000, against an average of 15·9 per 1000 for the previous eight years; the corrected death-rate was 13 3 per 1000, as compared with 14 4 per 1000 for the preceding eight years. Excluding visitors the death-rate was 11·5 per 1000. The zymotic death-rate was 0 35 per 1000. The birth-rate was only 15 8 per 1000 but Torquay contains a higher population of persons at the more advanced periods of life than obtains in the population of the country as a whole. Referring to deaths from phthisis Dr. Dunlop states that when deaths occur in private houses a notice is forwarded to the householder offering to fumigate the rooms with formalin free of cost, but this offer has only been accepted in a small percentage of cases. Dr. Dunlop adds that he believes a word from the medical attendant advising such fumigation would have more effect than any number of notices.

March 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Annual Dinner of the Edinburgh Royal Medical Society.

THE annual dinner of the Edinburgh Royal Medical Society was held on March 3rd. Owing to the illness of Dr. Shaw, the senior president, Dr. D. O. Ll. Fitzwilliams presided.

Sir William Turner, K.C.B., was the guest of the evening, whilst among the other guests present were the Lord Provost, Colonel Trevor, R.A.M.C., Sir John Batty Tuke, M.P., and the Rev. Dr. Cameron Lees. The toast of "The Guest" was given by the chairman in felicitous terms and was responded to by Sir William Turner in a most interesting and kindly manner.

Appointment of a King's Physician in Scotland.

The intimation that Professor Sir Thomas Fraser has been honoured by being appointed one of His Majesty's physicians in Scotland, has given rise to much satisfaction in university circles. The last holder of this honour in Edinburgh was Dr. George W. Balfour.

Small-pox in Edinburgh.

While there has been no alarming increase in the number of cases of small-pox reported in Edinburgh, fresh cases keep appearing at the rate of two or three each week and enough to keep the public health authorities actively on the *alert*.

Royal Edinburgh Asylum for the Insane.

The annual meeting of the corporation of the Royal Edinburgh Asylum for the Insane was held on Feb. 29th. The annual report of the managers showed that the daily average number of patients of all classes during the year 1903 had been 917, a decrease of 30 as compared with the preceding year. This decrease was mainly in the rate-paying patients who had numbered 542, as against 566 in the preceding year. In addition to the rate-paid patients accommodated in the asylum the managers had to find accommodation in other asylums for 153 patients from the Edinburgh city parish. The number of voluntary patients under treatment had been 25. The ordinary revenue amounted to £58,762 12*s.* 2*d.* and the ordinary expenditure to £53,868 5*s.* 8*d.*, leaving a surplus of £4894 6*s.* 6*d.* From this surplus the sum of £1970 was deducted as the annual instalment towards the liquidation of the debt on the West House, leaving a free surplus of £2924. The report of Dr. T. S. Clouston, the physician-superintendent, stated that the admissions last year numbered 411, of whom 196 were men and 215 were women. The total number of patients under treatment during the year had been 1361. The number of patients discharged had been 313, of whom 145 were men and 168 were women. The deaths numbered 119, of which 64 occurred in men and 55 in women. The majority of the deaths had resulted from one of four diseases—viz., general paralysis of the insane, senile decay with brain disease, tuberculosis, and apoplexy and ordinary brain softening. With regard to tuberculosis there had only been three deaths from that disease in Craig House since it was opened nine years ago and all three cases had been imported. In the West House there had been a considerable amount of tuberculosis and during the last ten years—the *years of overcrowding—there had been a decided increase* in the number of cases of that disease. Dr. Clouston then commented at some length on the increase of insanity and especially on the increase of alcoholic insanity. He suggested that the epidemic of influenza of 1890 by lowering the nervous tone might have tended to set up a craving for the stimulus of alcohol. Dr. Clouston concluded by making a plea to the general public to take a more rational view of mental disease which should be simply regarded as a disease of the brain and looked on in the same way as other diseases.

March 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Private Entrée at Dublin Castle.

THE private entrée at Dublin Castle has been restored to the President of the Royal College of Physicians of Ireland and the President of the Royal College of Surgeons in Ireland.

Small-pox on Achill Island.

A serious outbreak of small-pox has recently occurred on Achill Island, where between 20 and 30 cases are now being treated. It is said that the disease was imported from Glasgow in which city it is now prevalent. Mr. D. Edgar Flinn, one of the medical inspectors of the Local Government Board, visited the island with a view to advising as to the best means of preventing the spread of the affection. A temporary isolation hospital has been opened by the district council under the superintendence of Mr. T. H. Croly, the dispensary medical officer of the island, and the services of trained nurses have been obtained. A large proportion of the island population live under housing conditions which are most unhealthy, while the sanitary state of some of the congested villages is very bad.

Public Health of Dublin.

In connexion with the approaching visit of His Majesty the King it is satisfactory to note that the death rate of the city of Dublin is lower than usual. At a meeting of the public health committee held on March 1st Sir Charles Cameron reported that the death-rate from all causes for the week ending Feb. 27th, 1904, was 28·1 per 1000 persons living, the mean death-rate in a corresponding period of the previous ten years being 35·3. The death-rate for the Dublin registration area for 1903 was the lowest recorded, being 22·8 per 1000. The zymotic death-rate was also the lowest on record, being only 1·5, as against a mean rate of 2·8 for the previous ten years.

Health of Belfast.

From the report presented at the meeting of the city corporation on March 1st it appears that the number of cases of typhoid fever and the deaths therefrom have been very few and the disease seems to be dying out. The deaths from whooping-cough (there is at present a widespread epidemic) are still very numerous. During the month eight cases of small-pox were notified. The public health committee wish measles, whooping-cough, and phthisis all to be included amongst the notifiable diseases. It is unfortunate that the existence of small-pox is being concealed in the houses and the efforts of the sanitary officers to remove patients to the small-pox hospital are being resisted. It has been decided to grant £250 per annum for three years to deal with the foreshore nuisance at Cultra. 162 cases of zymotic disease have been notified between Jan. 24th and Feb. 20th—viz., 47 cases of scarlet fever, 40 of erysipelas, 26 of typhoid fever, 18 of diphtheria, 17 of simple continued fever, eight of small-pox, and three each of puerperal fever and membranous croup.

Queen's College, Belfast.

The Misses Riddel, who recently gave a munificent gift of £12,000 to the Royal Victoria Hospital, have presented £5000 to Queen's College, Belfast, for the purpose of founding a "Riddel demonstratorship in pathology and bacteriology" in connexion with the Musgrave chair of pathology founded by their cousin, Sir James Musgrave, Bart., D.L., in 1901. This endowment will secure a permanent assistant in the pathological laboratory.

Royal Victoria Hospital, Belfast.

At the bi-monthly meeting of the board of management of this hospital on March 2nd the Right Hon. W. J. Pirrie, on behalf of Mrs. Pirrie, handed over cash and securities to the value of more than £48,000, raised by her as an endowment fund for the hospital. This sum, together with the donation just mentioned of the Misses Riddel and £1000 given by the Right Hon. Thomas Sinclair and his family, brings the endowment fund up to £60,000, a sum in addition to £100,000 collected by Mrs. Pirrie for the building and equipment of the hospital. The following motion, which was proposed by the chairman, seconded by the Dean of Connor, and supported by Professor J. W. Byers on behalf of the medical staff was then passed by acclamation:—

[illegible]

Mrs. Pirrie, who was much affected, said that the work had been to her a labour of love and her one hope was that the hospital which was so near to her heart would prove a real boon to those for whose benefit it had been erected. The annual meeting, at which Mr. Pirrie is to preside, will be held on March 22nd.

The Lectureship on Medical Jurisprudence in Queen's College, Belfast.

No better selection or more popular appointment could have been made than that of Dr. Thomas Houston as joint lecturer on medical jurisprudence in Queen's College, Belfast.

March 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Cancer.

AT the meeting of the Academy of Medicine held on Feb. 25th M. Doyen read a paper in which he reminded the meeting that he had previously notified the existence of a microbe peculiar to cancerous tissues—namely, the micrococcus neoformans. This microbe when injected into animals had caused the formation of various tumours. Since 1901 he had treated 126 cases of malignant growth with injections either of cultures of the microbe of variable virulence or of its toxins. Of these 126 cases 58 had not benefited in any way, 47 were still under observation, and 21 might be considered as cured. Of the 47 cases under observation 29 had not so far shown definite enough signs one way or the other for an opinion to be arrived at, but they had improved at least temporarily. The remaining 18, although they had manifestly improved, were not included among the cures, for the new growths, although they were being absorbed, had not yet completely disappeared. The remaining 21 patients in whom the new growths had completely disappeared M. Doyen reckoned as cured. The tumours comprised lymphadenoma of the testicle with secondary growths in the groin, sarcoma of the muscles of the thigh, cancer of the stomach, cancer of the uterus with secondary growths in the pelvis, cancer of the tongue, epithelioma of the face with affection of the lymphatic glands, sarcoma of the tonsil, and epithelioma of the breast.

The "Femme Tuberculeuse."

A new department of social hygiene has just been set on foot in Paris under the name of "La femme tuberculeuse." Its object is to protect the young girl, the mother, and the child from tuberculosis by offering those who are menaced by the disease an opportunity of living in wholesome air during the period of enforced rest which may be considered necessary for the repair of their constitutions. The society has opened a dispensary in the Rue Carpeaux where mothers are taught how they should bring up their infants and where they can obtain milk of good quality so that they can give up suckling. The dispensary will also look after the disinfection of the lodgings and clothing of the tuberculous and will help the sick to live as hygienically as possible. Housewives and young girls can also be taught the elements of housekeeping at the dispensary which will be open on holidays. A house which has been leased in the suburbs will serve for a house of rest and in it there will be room for 120 pensioners. Finally, a convalescent home will be established in the centre of France where pensioners will be able to stay for six months in fresh air. The administrative council and the committee of patronage comprise various well-known medical men, such as Dr. Bouchard, Dr. Brouardel, Dr. Budin, Dr. Armand Gautier, and Dr. Pozzi. The subscription may be as low as one franc per annum.

Acid Medication of the Duodenum.

At the meeting of the Academy of Medicine held on Feb. 16th M. Enriquez read a paper in which he recalled the researches of Hallion, Delezenne, Frouin, and himself upon the above subject. He considered that the therapeutic problem was how to bring an acid in contact with the duodenal mucous membrane For his own part he had had recourse to capsules of tartaric acid. The capsule was made of gluten, a material which is refractory to the action of the gastric juice in an acid medium but which is easily attacked in an alkaline medium. He had treated in this way 16 patients in the wards under the charge of M. Brissaud and M. Ballet. In seven of these who suffered from marked constipation the bowels became regular. In five patients who suffered from constipation and muco-membranous colitis there was a rapid improvement in the symptoms. In three cases of nervous motor dyspepsia the treatment had a markedly favourable influence upon the subjective symptoms, such as feelings of weight, sleepiness, and swelling. It would appear therefore that acid medication of the duodenum exerts a special influence upon the secretory functions in man.

Limitation of the Dietetic Use of Chloride of Sodium in Hyperchlorhydria.

Now that the importance of the proportion of chloride of sodium present in the fluids of the body is recognised, and in consequence also of the researches of M. Widal on the subject of "déchloruration," attention is being given to the relation which an increased quantity of chloride of sodium in the fluids bears to hyperchlorhydria. Chloride of sodium is the only inorganic alimentary principle which is insufficiently represented in ordinary food and consequently has to be added specially thereto. It is somewhat singular that the desire for chloride of sodium which everyone experiences varies a good deal with the nature of the food. The carnivora can do without it very well but it is indispensable to the herbivora. It is certain that those who live in towns and are meat-eaters to a great extent take only a fourth of the quantity of chloride of sodium used by the peasantry who eat a larger proportion of vegetables. Some persons, however, take an excessive amount of chloride of sodium, even as much as three quarters of an ounce or an ounce per day. The kidneys, which are the organs of elimination, are thereby overworked and it is thought that many cases of nephritis originate in this way. At any rate, patients suffering from nephritis very soon improve when they are placed on a dietary decidedly poor in salt and in them it is possible to cause œdema and swelling of the legs to disappear and to reappear at will by withholding salt in the one case and supplying it in the other. The relations of chloride of sodium to disease of the stomach are not less singular. It is reasonable to suppose that the hydrochloric acid of the gastric secretion is formed at the expense of the chloride of sodium. Persons who take little salt have weak stomachs and in tropical countries, where much salt is eliminated by the perspiration, the functions of the stomach are impaired, whilst on the other hand those who take large quantities of salt without the justification afforded by a diet mainly vegetable suffer from overacidity of the gastric juice and some degree of interference with the action of the kidneys. It has therefore been proposed to treat hyperchlorhydria by restricting the ingestion of salt as in the case of nephritis. The subject was discussed not long ago by M. Linossier at a meeting of the Society of Biology and at the same meeting M. Laufer said that in cases of obstinate hyperchlorhydria with occasional exacerbations and vomiting the patients improved considerably when taking ordinary mixed diet without the addition of salt, but every time that they took two or three grammes (30 or 40 grains) of salt with their food the pain returned.

The Budget of the Assistance Publique for 1904.

The budget of the Assistance ·Publique for 1904 has reached the sum of nearly 64,000,000 francs. Despite various economies which have been carried out the expenses of the year 1903 have exceeded the estimates by over 1,200,000 francs. Food and drink are responsible for 655,000 francs of this excess and the consumption of milk goes up every year, the yearly sums expended for this beverage having risen from 482,000 francs in 1891 to 1,189,000 francs in 1903. It must not be thought that the number of patients has increased in this proportion, for the patients have only increased by 15 per cent. and the consumption of wine has not proportionately diminished. Expenses due to extra comforts supplied to nurses have also increased, while the surgeons have exceeded the estimates for dressings, instruments, and apparatus by 80,000 francs.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Remedy against Sea-sickness.

ANÆSTHESIN, which was recommended by Professor von Noorden in the treatment of cases of gastric hyperæsthesia, nervous dyspepsia, and gastric ulcer, has also proved efficacious in sea-sickness. Dr. Schliep formerly a medical officer of a passenger steamer, writing to the *Deutsche Medicinische Wochenschrift*, says that on his voyages to America, Australia, and the Pacific he used to administer anæsthesin as a prophylactic to passengers who on previous voyages had suffered from sea-sickness. From three to four half-gramme powders were given during the first few hours at sea and were repeated on the following day, the result being that the majority of those passengers were not sea-sick. The remedy proved efficacious even after the first symptoms such as giddiness and loss of appetite had made their appearance, but no benefit was obtained when sea-sickness had fully set in, the patients being as a rule too much overcome by their sensations to swallow any medicine at all. It is essential to administer full doses of from two to three grammes a day from the beginning. The use of the drug is not attended with any risk or danger. Dr. Schliep recommends, therefore, that anæsthesin should form part of the stock of medicines carried on board ship.

Dentition and Tuberculosis.

In a paper read before the Berlin Medical Society Dr. Westenhoeffer gave an account of some experiments on the occurrence of tuberculous infection in early life. He made subcutaneous injections of tuberculous material in the lumbar region of 120 guinea-pigs, 30 rabbits, and three calves The small animals died after two or three months and the calves were killed after that time. At the necropsies caseous changes were found at the site of the injection and in the inguinal, retroperitoneal, and in some cases the mesenteric and perirenal glands. The spleen and the liver were often tuberculous, whilst tuberculosis of the lungs was rather rare. Tuberculous infection might obviously spread through the lymphatic vessels. In 12 cases where the bronchial glands were tuberculous miliary tuberculosis o[illegible] an observation in accordance [illegible] views. Dr. Westenhoeffer found [illegible] sometimes the course of the tuberculous infection was rather irregular, not always going along the lymphatic vessels, so that glands of distant regions were affected whilst intermediate glands were still healthy. Attention was drawn to the fact that tuberculosis was never present in children under three months of age and is rather frequent after the first year. Dr. Westenhoeffer was of opinion that the frequency of glandular tuberculosis in that period is in connexion with dentition, during which the mucosa of the mouth becomes swollen and somewhat inflamed so that infection may easily occur. Similar conditions exist in the lower animals. Nearly all mammals are either born with teeth or get them within the first fortnight after birth. The only exception is the pig, in which animal the teeth are late in making their appearance. It was remarkable that tuberculosis developed in pigs after dentition and that the lymphatic glands of the neck became swollen first just as in the scrofula of children. Dr. Westenhoeffer said that the frequency of tuberculosis of the lymphatic glands in the poorer classes was principally due to the uncleanly state of their homes. Children during dentition were inclined to put things in their mouths, a practice which is not free from risk in insanitary surroundings. Alluding to Professor Behring's theory as to the propagation of tuberculous infection through the intestines he said that the alleged permeability of the intestinal mucosa only existed in the first two days of life; the intestines of children and of adults did not differ as to their liability to tuberculosis. He agreed with Professor Behring that the struggle against tuberculosis must begin in childhood, although the points of view from which they regarded the general question of tuberculous infection were different in some respects.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The First Successful Ovariotomy performed in Switzerland.

THE following details may be of interest to the medical profession in England. In December, 1903, a clergyman's widow died at Zürich at the ripe age of 83 years, succumbing to senile marasmus aggravated by broncho-pneumonia. Nearly 40 years ago she suffered from an abdominal tumour which threatened her life. After various methods employed to prevent the rapid growth of the tumour had all signally failed her medical attendants and Professor Breslau, who at that time occupied the chair of obstetric medicine at the University of Zürich, called i[illegible] Wells of London who perform[illegible] 1865, and removed an ovarian [illegible] 56 pounds (25 kilogrammes). [illegible] and outlived most of her medical attendants. It may be mentioned here that a Dr. Carl Gustav Jung performed the first laparotomy (which, however, was unsuccessful) in Basle as early as 1851.

Attendance at Medical Schools in Switzerland.

The number of medical students entered at the five Swiss universities during this winter term, 1903-04, amounted to 1654, a slight decrease as compared with 1696 in the corresponding period a year ago. The fair sex still preponderates, there being 891 lady students (874 of whom are foreigners) and 763 male students; of the ladies five are studying at Basle, 151 at Geneva, 177 at Zürich, 181 at Lausanne, and 377 at Berne. The total number of medical students at each of the five universities is as follows: 140 at Basle, 275 at Lausanne, 307 at Geneva, 388 at Zürich, and 544 at Berne. The establishment of a medical school reserved for lady students is being seriously discussed in the lay and medical press.

Fulminant Hæmorrhagic Purpura.

Dr A. von Lerber has published an account of a rare case of purpura terminating fatally in 12 hours. The patient was a healthy girl 13 months old, one of a healthy but slightly neurotic family. The child had not been ill except once when she had a slight attack of bronchitis which did not call for medical treatment. During the night of Jan. 5th she became restless and seemed very collapsed at 6 A.M., so that a medical man was called in. At 7 A.M. on the 5th he found the child quietly taking food. Distributed over the chest, arms, and legs he observed a number of hæmorrhagic spots of a bluish-red colour of about the size of lentils and even larger. The pulse was quick but there was no pyrexia He prescribed a warm bath. Called in again at 9 30 A M he found numerous similar spots coming out all over the face and body, some as large as a five-shilling piece. At 11 30 A.M. the temperature was 99° F., the respirations were 60 per minute, and the pulse could not be counted. The child became comatose and passed away quietly at 1 P M. A post-mortem examination was not permitted. Dr. von Lerber remarks that a sister of the patient died four years previously from broncho-pneumonia at the age of two years after a skin eruption which may have been either measles or a "similar skin affection," as the mother called it.

Zurich, Feb. 29th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

American Nurses for the Japanese Army.

THE United States is to aid in nursing the wounded and sick Japanese soldiers. Dr Anita Newcomb McGee, who organised a corps of nurses during the Spanish-American war in 1898, first in Cuba and afterwards in the Philippines, has offered to fit out a nursing staff for service with the Japanese army. The Japanese Minister in Washington has accepted the offer on behalf of his Government and Dr. McGee will leave in the early part of March with several nurses to establish a field hospital in Japan. There are to be formed committees of women in different parts of the country to raise funds for the support of the nurses. More nurses will follow if the subscriptions are large enough to cover expenses.

Typhoid Fever and Diphtheria at the University of Minnesota.

[illegible] that somewhat [illegible] or exist at the se[illegible] ably close for St[illegible] has publicly the balance of [illegible] warned the students against the city water. A further outbreak of typhoid fever is feared. A faculty health committee has been appointed to fight the contagion.

Consolidation of the Medical Society of the State of New York and the New York branch of the American Medical Association.

The consolidation of the two medical organisations of New York State is, at the time of writing, practically an accomplished fact. For many years there have been more or less serious differences between these two bodies, but at length the hatchet has been buried and a satisfactory agreement has been reached. This result has been mainly due to the [illegible] profession [illegible] organisations to an agreement. The question upon which the societies were divided was one of ethics, the Medical Society of the State of New York making a stand against professional sectarianism and declaring against ethical differences of opinion among legally licensed practitioners of other schools. At the annual meeting of the Medical Society of the State of New York, held in Albany on Jan. 26th, the following motions were unanimously adopted:—

> Resolved, that the report of the joint committee of conference be accepted and that the proposed agreement for the consolidation of the Medical Society of the State of New York and the New York State Medical Association be and the same is hereby approved, and the president of the society is hereby authorised and directed to execute the same in the name and behalf of the society, and the secretary is hereby authorised and directed to affix the corporate seal thereto; and be it further resolved that the committee of the society heretofore appointed for the purpose of bringing about the consolidation—namely, Dr. Henry L. Elsner, Dr. A. Jacobi, Dr. A. Vanderbeor, Dr George Ryerson Fowler, and Dr. Frank Van Fleet—be and they are hereby continued as such committee with full power and authority to do whatever may be necessary to carry the agreement into effect.

Action on the adoption of the report of the joint committee of conference, together with the proposal of motions ratifying the action of the State society, will be taken at the stated meeting of the Medical Society of the State of New York to be held on Monday, Feb. 29th.

Tenement Children and Tuberculosis.

At a recent meeting of the Association for Improving the Condition of the Poor an appropriation of $15,000 (£3000) was made for the maintenance at the seaside of 50 New York tenement children suffering from non-pulmonary forms of tuberculosis. The association wishes to educate the general public to a knowledge of the fact that a large percentage of children known merely as cripples are suffering from tuberculosis and can be cured. Dr. Hermann Biggs of the New York Health Department declares that there are in the New York tenements alone from 3000 to 4000 children under 15 years of age suffering from scrofula and tuberculosis of the bones, the joints, and the lymphatic glands. It is, of course, a well-known fact that tuberculosis of the lungs affects but a relatively small number of children under 15 years of age.

Surgeon wanted on the Panama Commission.

The committee on medical legislation of the American Medical Association has requested President Roosevelt to appoint on the Panama Canal Commission a member of the medical profession and has suggested that Colonel William C. Gorgas is well qualified for the position. Colonel Gorgas is a surgeon in the army and is widely known for his researches in Cuba into the causes of yellow fever. The fact is urged that—

> Under both the French administrations at the Isthmus the engineering problems themselves, to the chagrin of the medical profession of the world, failed of accomplishment largely through the frightful mortality among officers and labourers consequent upon lack of authority on the part of medical officers intrusted with the work of sanitation; that the same conditions of insalubrity exist now that existed then and that consequently the sanitary problems are to be recognised as second in importance, if second at all, only to those connected with the engineering department.

New York Eye and Ear Infirmary.

The board of directors of the New York Eye and Ear Infirmary has decided to curtail the scope of the work of that institution after May 1st in the event of sufficient funds for its maintenance not being collected. Even after March 1st no patients will be received in the part of the hospital known as Platt Pavilion in which contagious diseases of the eye are treated. The closing of this wing of the hospital would be a misfortune for many infants living in the very poor districts of the east side. The infirmary has been in existence for 86 years and is considered to be the foremost institution of its kind in the United States.

Feb. 27th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Quarantine against Small-pox.

IN consequence of an outbreak of small-pox in Christchurch, New Zealand, the various boards of health in Australia have declared New Zealand to be infected and all vessels from New Zealand ports will be quarantined and no passengers allowed to land for 15 days unless successfully vaccinated within the last two years or until *pratique* is granted by the health authorities. The necessity of placing quarantine regulations under Federal control as speedily as possible is again made manifest by the different adopted by the several States in this instance. The vessel to arrive from New Zealand at Australian after notification of the outbreak was the *Mocraki* Hobart. She was allowed to berth and to unship and ship cargo but all passengers were prohibited from landing. The Tasmanian passengers were therefore taken to Melbourne, the next port of call. On arrival at Phillip Heads the *Mocraki* was boarded by two medic officers of the Board of Health. The passengers wer examined and it was found that all who had come fro Christchurch or had passed through that city during the tim of the outbreak of small-pox had been successfully vac cinated within the last two years. The names and addresse of all the passengers were taken and on their giving assu ances to report to the Board of Health in case of illne they were allowed to land. The 50 passengers for Hoba can now return there by way of Launceston. The Board Health of New South Wales is quarant [illegible] Christchurch only. In Queensland a [illegible] issued ordering that all vessels from N [illegible] quarantined until granted *pratique* by the health authoritie Some uniformity of action is obviously necessary.

Bubonic Plague.

Some time ago the Government of West Australia co missioned Dr. Anderson to visit India and to inquire into t occurrence and treatment of bubonic plague. Dr. Anders has sent in a report in which he states that plague is not in a great majority of cases a contagious disease as ordinarily understood and that the discovery of a case in a general hospital need not necessitate the quarantine of the whole institution. A case of supposed bubonic plague was discovered in a coloured seaman on board a steamer at Williamstown, Melbourne. The steamer was placed in quarantine pending inquiries, the result of which was that the case was not plague.

Tuberculosis.

The Victorian Year-book for 1902, which has just made its belated appearance, includes a contribution by Dr. D. Astley Gresswell, chairman of the Board of Public Health, entitled "The Presence of Tuberculosis in Victoria." He mentions that from 1863 to 1887 the death-rate from phthisis and other tuberculous diseases remained fairly constant. In the triennial period commencing at the latter year the average yearly rate per 100 000 inhabitants for the metropolitan districts was 283 and for the extra-metropolitan 119 A steady improvement then set in and during the triennial period 1899–1901 in the metropolitan districts the average yearly deaths from phthisis were 144 per 100,000 and those from other tuberculous diseases were 42 per 100,000. Some few months ago, as mentioned at the time, the Board of Health of Victoria made tuberculosis a notifiable disease under the provisions of the Health Act. This procedure has been much opposed by many members of the medical profession. In his annual report to the Board of Health, Dr. Wilkinson, health officer of Preston, referred to the subject and observed that from a long experience in an isolated district with a settled population he was satisfied of the small risk of contagion and had never seen a case of its occurrence, although for over 20 years he had watched the other members of households where one had been attacked with tubercle. On the other hand, the reporting and segregating of such cases would have inflicted great hardship. Dr. D. Turner, who as examining medical officer to the sanatorium for consumptives in Victoria has had exceptional opportunities for observation, has forcibly expressed his dissent from the action of the Board of Health. He records numerous instances of the hardship inflicted by the opinions now promulgated as to the contagiousness of tubercle—opinions which his experience shows to be exaggerated greatly. The plans for the new "Kronheimer" wing for consumptives at the Austin Hospital have been approved. The building will accommodate 30 beds on each floor, making the total number for consumptives 102 The new wing will not be utilised, however, until the question of its maintenance has been settled. Like the infectious diseases hospital the building will lie idle unless the Government comes to the assistance of the committee which at present it absolutely declines to do.

Preservatives in Food.

As previously stated in this column[1] the manager of a concentrated milk company in Sydney was charged with an offence against the regulations of the Board of Health in [illegible] [illegible]ic acid in a proportion exceeding [illegible] The defendant contended that [illegible] d on the ground that the regulation was invalid, because unreasonable, and that the provision made did not "regulate" as required by the Health Act but for practical purposes prohibited the use of boric acid as a preservative. The magistrate decided that the regulation was not unreasonable, convicted the defendant, and fined him in the sum of £2, in default seven days' imprisonment with hard labour.

---

[1] THE LANCET, Feb. 27th, 1904, p. 618.

Infantile Mortality.

The Victorian Year-book gives some figures respecting infantile mortality in Australia. The average deaths under one year of age to 100 births for the period 1891–1901 is: Western Australia, 14 5; New South Wales, 11·2; Victoria, 11·1; South Australia, 10·5; Queensland, 10·3; and Tasmania, 9 6. Figures have been published showing the percentage of children who died before reaching the age of 12 months in Victoria during a series of years. From 1866 to 1902 the two highest percentages were 12·91 during the period 1866–70 and 13 41 in 1898, while the two lowest were 10 23 in 1895 and 9 53 in 1900.

Medical Society of Victoria.

The annual meeting of the Medical Society of Victoria was held on Jan. 13th. The report stated that there were 290 members and that 23 new members had been elected during the year. The average attendance at meetings was 36. The following officers were elected for the year 1904:—President: Dr. G. T. Howard. Vice-Presidents: Mr. M. U. O'Sullivan and Dr. A. J. Wood Treasurer: Dr. C. H. Mollison. Secretary: Dr. L. J. Balfour. Librarians: Mr. A. W. F. Noyes and Dr. H. D. Stephens. Committee: Dr. P. Bennie, Dr. W. Boyd, Dr. Buchanan, Dr. Gault, Dr. Lawrence, Dr. Moore, Mr. F. W. W. Morton, Mr. R. Hamilton Russell, Mr. W. Beattie Smith, and Dr. R. R. Stawell. The retiring president, Mr. Russell, read the annual address, taking a somewhat unusual course by dealing with the special subject of the Congenital Origin of Hernia, a subject which he has discussed on several occasions during the last five years.[1]

Hospital Affairs.

The sixteenth annual report of the Royal North Shore Hospital, Sydney, stated that the first portion of the new hospital had been opened and that the institution had remained practically full ever since. During the 12 months there were 153 patients treated in the old hospital, of whom 120 were discharged cured and nine died, while nine were removed to the new building. In the new hospital 340 patients had been treated, of whom 239 were discharged cured, and 30 died, leaving 42 under treatment at the end of the year. The average daily number resident in the old hospital was 21·65 and in the new 39. The total number of deaths (of which eight occurred within 24 hours of admission) was 39, being 8·05 per cent.—The annual report of the Balmain Hospital stated that the number of patients treated in the institution last year had been 339 in the indoor department and 2395 in the outdoor, as against 341 and 2193 respectively for 1902. The mortality on the year's cases had been 5 8 per cent.—By the will of the late Mr. Felton, senior partner in the firm of Felton, Grimwade and Co, wholesale druggists, Melbourne, the hospitals of Melbourne will be very largely benefited. He left between £400,000 and £450,000 to be invested by trustees and half the income is to be devoted to charities and half to the purchase of works of art "calculated to raise or improve the public taste." With regard to the bequest for the charities the testator said:

> [illegible]

[illegible] staff of the Melbourne Hospital [illegible] of the committee of management [illegible] aiming that under the Hospital [illegible] placed under the physicians and surgeons who were to be elected by the subscribers. The specialists already appointed by the committee are dermatologist, ophthalmologist, aurist, skiagraphist, medical electricians, and anæsthetists. The committee has now obtained counsel's opinion on the subject which is that the committee has not the right to appoint specialists.

New Border Medical Association.

A conference of medical practitioners from Albury, Corowa, Wodonga, Rutherglen, Chiltern, and Wangarratta was recently held, when it was decided to form a "Border Medical Association." Dr. Andrews was elected President, Dr. C. F. Harkin Vice-President, and Dr. Lang secretary. Chiltern was selected as the meeting place. It is proposed later to affiliate the association with the New South Wales branch of the British Medical Association.

Appointments.

Dr. C. W. Reid, senior medical officer of the Department of Lunacy, at present acting as port health officer at Sydney, and visiting medical officer to the Shaftesbury Reformatory, has been appointed port health officer of Sydney in the place of Dr. William Peirce who has retired. —Dr. Charles MacLaurin has been appointed a member of the Police Medical Board, New South Wales, in the room of Sir H. Normand MacLaurin, M L C.

A Brave Medical Man.

At a recent serious fire at the Wallaroo Mines, South Australia, heroic work was performed by Dr. H. R. Letcher. Finding that the lives of the men underground were endangered through want of medical aid Dr. Letcher went down and worked in the poisonous air for hours until he was utterly exhausted.

Obituary.

Dr. J. G. Carstairs, one of the oldest practitioners of Geelong, Victoria, died on Jan 13th. Dr Carstairs was a son of the late Surgeon W. Carstairs of the East India Company's service and was born at Poonah, in the Bombay Presidency, India, on June 28th, 1829. He studied medicine at the University of Edinburgh where he graduated as M.D. in 1850. He commenced practice in Moorabool-street, Geelong, in February, 1854, and soon acquired a large practice. He was universally respected and was especially good to the poor. For many years he was health officer of the city and took a great interest in epidemiological questions, contributing many papers to the local medical societies on influenza, measles, and like subjects, the occurrences of which he believed were influenced by the amount of ozone in the atmosphere.

Feb 2nd.

Obituary.

ALEXANDER DAVIDSON, M.A., M.D. EDIN., F.R C.P. LOND.,

CONSULTING PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY.

IT is with much regret that we have to record the death of Dr. Alexander Davidson, at the age of 66 years, which event took place on March 3rd at his residence at 2, Gambier-terrace, Liverpool. He had been in failing health for some time and in October of last year was confined to his room. He recovered sufficiently to enable him to resume a part of his professional work but apparently the exertion was more than he was able to endure as a serious relapse occurred about four weeks ago from which he never rallied. Dr. Davidson was born in Edinburgh in 1838, being the son of the late Rev. Dr. Davidson of that city. He graduated as Bachelor of Medicine at the University of Edinburgh in 1863 and as Doctor of Medicine in 1872. He was elected a Fellow of the Royal College of Physicians of London in 1885, having been admitted to its Membership in 1874. He was formerly assistant physician to the Liverpool Infirmary for Children and honorary physician to the Liverpool Northern Hospital and in 1876 was appointed honorary physician to the Liverpool Royal Infirmary, from which post he retired in the spring of 1897 and was then appointed consulting physician. He took a leading part in the reconstruction of the old Liverpool Royal Infirmary School of Medicine which in 1881 became the medical faculty of University College, Liverpool, and is now the medical faculty of the University of Liverpool. He was the first lecturer on pathology and when the old school of medicine was merged into University College he was promoted to the rank of professor. Upon resigning that post some years ago he was honoured with the title of emeritus professor and within the last few months was elected to a seat on the medical faculty of the University of Liverpool *honoris causâ*. His clinical teaching was highly valued for its thoroughness by the students of the Royal Infirmary and great confidence was placed in his judgment by his professional brethren. His reputation as a physician was not confined to Liverpool but extended to the surrounding districts and North Wales. During his term of office at the Royal Infirmary, which occupied nearly 21 years, his advice and guidance in matters affecting the general interests of the hospital were eagerly sought by the chairman and members of the managing committee, his singleness of purpose and his integrity of character being so fully acknowledged. He also gave valuable assistance to the building committee of the new Royal Infirmary in matters connected with its sanitary and other requirements. At one time Dr. Davidson took a large interest in the Lancashire and Cheshire branch of the British Medical Association, of which he had been honorary secretary and president. He also took a great interest in the nurses' home and training school for nurses in connexion with the Royal Infirmary and in the Queen Victoria District Nursing Association. He was always ready to attend the sick nurses and by them he will be sadly missed. Some few years ago he was offered the presidentship of the Liverpool Medical Institution but he declined the honour for reasons of health. The profession of Liverpool esteemed him as a model of uprightness and single dealing and his example will not soon be forgotten by his numerous friends and former students. He leaves a widow and a son who is an undergraduate at Trinity College, Oxford.

---

[1] Mr. Russell's address is published in full on p. 707 of our present issue.—ED. L.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. A. Gross, *privat-docent* of internal medicine in the University of Kiel.—Dr. Magnus Blix, professor of physiology in the University of Lund, at the age of 55 years. He graduated in Upsala and was for some years assistant to the professor of medical physics there. He published numerous papers on the Physiology of Muscles and especially on that of flight in birds.—Dr. Hermann Emminghaus, formerly professor of mental diseases in the University of Freiburg. He was born in Weimar in 1845 and studied in Göttingen, Jena, Vienna, and Leipsic. He was *privat-docent* in Würzburg and professor in Dorpat (Iurieff) before being offered the chair in Freiburg in 1886. He wrote various monographs on Mental Diseases and the portion of Penzoldt and Stintzing's "Handbook of Therapeutics" dealing with these.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Dr. J. G. Adami and Professor H. T. Bovey, F R S, of Montreal will represent the University at the jubilee festivities of the University of Wisconsin to be celebrated in June next.—At the Congregation held on March 5th medical degrees were conferred as follows:—

Doctors of Medicine.—S. H. A. Lambert, St. John's; and W. M. Willoughby, Gonville and Caius.
Bachelor of Medicine and Bachelor of Surgery.—G. S. Haynes, King's.
Bachelors of Medicine.—R. S. Drew and C. M. Murray, Pembroke; and P. Hardy, Trinity Hall.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Emil Villinger has been recognised as *privat-docent* of Neurology and Neuro-pathology.—*Berlin:* Dr. Heinrich Haike has been recognised as *privat-docent* of Otology.—*Bonn:* Dr. Karl Reifferscheid has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Bordeaux:* Dr. Verger and Dr. Abadie have been appointed, after *concours*, *agrégés* of Medicine.—*Copenhagen:* Dr. Oskar Bloch has been transferred from the chair of Clinical Surgery to that of Operative Surgery. Dr. Thorkild Rovsing has been appointed to the chair thus vacated.—*Florence:* Dr. Giuseppe Levi has been recognised as *privat-docent* of Anatomy.—*Halle:* Dr. Siegert of Strasburg has been offered the Extraordinary Professorship of Children's Diseases vacant through the death of Dr. Pott. Dr. Alfred Hoche of Freiburg has been offered the chair of Psychiatry vacated by Dr. Ziehen who goes to Berlin but he has declined it.—*Heidelberg:* Dr. Karl Bonhöffer of Königsberg has been appointed to the chair of Psychiatry.—*Iurieff (Dorpat):* Dr. Druzhinin has been allowed to retire from the chair of Surgery on account of the infirm state of his health. Dr. Rostoffsteff has been appointed Extraordinary Professor of Operative Surgery.—*Lille:* Dr. Verdun has been appointed Professor of Medical Zoology and Pharmacy; Dr. Fockeu, Professor of Materia Medica and Botany; and Dr. Inglerans, after *concours*, *agrégé* of Medicine.—*Lemberg:* Dr. Anton Jurasz of Heidelberg has been offered the newly created Professorship of Ear and Throat Diseases.—*Lyons:* Dr. Nicolas and Dr. Charvet have been appointed *agrégés* of Medicine.—*Montpellier:* Dr. Ardin-Delteil has been appointed, after *concours*, *agrégé* of Medicine.—*Nancy:* Dr. Richon and Dr. Hoche have been appointed, after *concours*, *agrégés* of Medicine.—*Naples:* Dr. Francesco Vigorita has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Paris:* Dr. P. Carnot, Dr. Claude, Dr. Balthazard, Dr. E. M. Labbé, and Dr. Macaigne have been appointed, after *concours*, *agrégés* of Medicine.—*Pisa:* Dr. Luigi Adolfo Oliver has been recognised as *privat docent* of Midwifery and Gynæcology.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The festival dinner of this association will take place at the Trocadéro Restaurant, Piccadilly-circus, London, W., on St. Patrick's Day, March 17th, at 7.15 P.M. Tickets may be obtained by members from Mr. E. Canny Ryall, 30, Harley-street, W.

COTTAGES *v.* TENEMENTS.—The sanitary committee of the city council of Manchester is engaged in a perpetual warfare against overcrowding and insanitary dwellings. One of the chief difficulties is to make provision for those displaced by the closing of the latter, an instance of which was given by one of the aldermen at the meeting of the council on March 2nd. Sometimes land cannot be obtained where it is most wanted and however unsavoury the locality may be those accustomed to live in it seem unwilling to go elsewhere. Large sums have been spent by the corporation in tenement dwellings, large buildings of several storeys with various conveniences as to water-supply, &c., but they are not very popular. The architect has to make his plans so as to utilise every inch of space and the result is a collection of tenements, one storey above the other, like the combs in a wasps' nest, and partaking more or less of the doll's-house character. The sanitary committee recommended at the same meeting the erection of 16 cottages and 144 tenements in three storeys in Bradford-road, but an amendment was moved in favour of occupying the whole of the site with cottages. This would reduce the accommodation for tenants from 533 persons to 328 and one gentleman said there would be an annual loss of at least £200 The "barrack" dwellings are not popular; people do not like the want of privacy or the noise of "children clattering over their heads," and one speaker said that the woes of the tenement dweller were described in a song with the refrain, "I live underneath." There can be no question that it is better to distribute people over a wide area than to put more on an acre by piling storey on storey, but unfortunately it is more costly. How far this may be recouped by the better health of those living in the cottages is an interesting question. However this may be, the amendment was carried.

ROYAL DENTAL HOSPITAL.—The annual general meeting of governors was held at the hospital on March 10th, Mr. Richard Winch, Vice President of the institution, being in the chair. The committee of management reported a total of 97,830 cases receiving attention during the year, being 8495 more than in 1902. Anæsthetics were given in 35,619 of the cases, 3998 more than in the previous year. Two paid house anæsthetists have been appointed in addition to the honorary staff, while the increase of work, although gratifying to the committee and staff, brings with it additional responsibilities, and they earnestly appeal for greater support from the public to enable them to carry on the work of the hospital satisfactorily and at the same time to pay the yearly sum of £3000 for interest and part repayment of loan for building the new hospital A legacy of £300 has been received from the executors of the late Mr. Richard Bishop and has been used towards the reduction of the debt. In answer to the appeal made last year to pay for the new operating chairs £962 2*s.* 6*d.* have been received, leaving

£414 13s. still owing. Donors of chairs (15 guineas each) become life governors of the hospital and are entitled to the usual privileges and to have their names affixed to the chairs presented. New annual subscriptions and donations will be gratefully received by the bankers, Messrs. Barclay and Co., 1, Pall Mall East, S.W., by the treasurer, Mr. F. A. Bevan, and by the secretary, Mr. J. F. Pink, at the hospital.

CHILDREN'S COUNTRY HOLIDAY FUND.—CHANGE OF TREASURER.—The Earl of Arran has consented to be treasurer of the Children's Country Holiday Fund, a post which the Right Honourable Alfred Lyttelton felt obliged to resign on accepting office as Secretary of State for the Colonies.

PROVINCIAL HOSPITAL, PORT ELIZABETH.—The forty-eighth annual report of the Provincial Hospital, Port Elizabeth, South Africa, dealing with the events of the year ended Dec. 31st, 1903, shows that during that time 1640 in-patients were treated, as compared with 1670 in 1902. Of this number 996 were Europeans and 644 were coloured persons and natives. There were 182 deaths—namely, 72 of Europeans and 110 of coloured persons; 106 patients remained under treatment at the end of the year. There were 8991 attendances of out-patients. The following are a few of the principal diseases for which patients were admitted: enteric fever, 99 cases, with 21 deaths; phthisis, 73 cases, with 49 deaths; venereal disease, 63 cases, with one death; alcoholism, 124 cases, with 12 deaths; and 421 cases the result of violence (including fractures), with 12 deaths.

UNIVERSITY OF LIVERPOOL: FACULTY OF MEDICINE.—A diploma in veterinary hygiene has been instituted to provide training, and recognition of such training, for veterinary surgeons upon parallel lines to that required for the diploma in public health so that veterinarians may adequately coöperate with public health officers in the carrying out of hygienic reform. The diploma is to be granted only to qualified veterinary practitioners after a thorough course of practical training in the university veterinary school in the subjects of veterinary hygiene, comparative pathology and bacteriology, parasitology, veterinary toxicology and jurisprudence, sanitary law, administration, and reporting. An advertisement of the diploma and the conditions under which it is granted appears in our present issue. The regulations for the recently established diploma in tropical medicine of the University of Liverpool only permit the granting of the diploma to men taught in the university school, that is, only to those for whose thorough training the university can be answerable. Particulars with regard to the diploma and the regulations for it will be found in our advertisement columns.

NEW HOSPITAL FOR WOMEN, EUSTON-ROAD, N.W.—The annual meeting of the subscribers to this hospital was held on March 8th, Adeline, Duchess of Bedford, presiding. During the last year 612 in-patients had been treated and the number of new out-patients had been 7629. There were 7879 out patients who renewed their letters and the total attendances during the year amounted to 35,122. The receipts for the year, apart from legacies, &c., amounted to £5758. The expenditure account showed an adverse balance of £35 and, in addition, the unpaid bills amounted to £354. Only 52 beds were available and the pressure on the out-patient department called for further accommodation. A special small ward for minor operations was also needed. Sir William H. Broadbent said that the hospital was doing excellent work. It was not only a hospital for women but it was also a valuable training ground for students. The committee announced with deep regret the retirement of Mrs. E. Garrett Anderson, M.D., from the committee of management of the hospital and her work was highly commended. She would, however, remain on the consulting staff. Her place on the committee will be taken by Mrs. M. A. D. Scharlieb, M.D.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Nurses and Private Nursing Homes Bill.

THE Bill to provide for the better training and registration of nurses and for the voluntary registration of private nursing homes, to which reference was made in a previous issue of THE LANCET, has now been presented. Its nominal promoter, the Hon. Claude Hay, has obtained the support of Mr. Bignold, Mr. H. D. Greene, Major Bagot, Lord Cecil Manners, and Mr. Ian Malcolm.

Opposition to the Pharmacy Bill.

Mr. Harwood has given notice of his intention to move the rejection of the Pharmacy Bill, the leading provisions of which were explained in a note last week. It is understood that the point upon which most controversy is likely to arise is the clause which seeks to make it obligatory that the directors of companies which sell patent medicines should be qualified chemists. This is described by Mr. Harwood and others as an effort to make the selling of drugs "a close corporation"—in other words, to force the trade in patent medicines into the hands of the druggists.

The Medical Members of Parliament.

A meeting of Members of Parliament who are also members of the medical profession was held at the House of Commons on Tuesday last. Dr. Farquharson presided and among those present were Sir Michael Foster, Sir John Batty Tuke, and Dr. C. F. Hutchinson. It has been felt by medical Members of the House that when the medical side of public questions comes up for discussion good service could be done by concerted action on their part and a committee has now been formed with that object in view. Sir Michael Foster has agreed to act as honorary secretary of the committee.

HOUSE OF COMMONS.

THURSDAY, MARCH 3RD.

Accidental Suffocation of Infants.

Captain NORTON asked the Home Secretary whether he could furnish a return for the last five years of the number of infants accidentally suffocated in bed with the proportion of such deaths in London, Liverpool, and Manchester and with the number of cases that occur in December and January compared with any other two months.—Mr. AKERS-DOUGLAS, in reply, said: I scarcely think that this is a

officers and men
been inoculated

enteric inoculation has been
of special interest and will on no account be neglected. If at a late

stage I can give the hon. Member the information he asks for I will do so.

Small-pox in Scotland.

Mr. JOSEPH DEVLIN asked the Secretary for Scotland whether his attention had been directed to the increase of small-pox in Greenock, whether he was aware that the hospital accommodation was insufficient and the buildings were overcrowded, whether patients were detained sufficiently long to avert danger of their spreading the disease after discharge, whether the reception house was well situated and sufficiently commodious for the proper isolation of all "contacts," and what steps he proposed to take to insure the provision of adequate hospital and reception-house accommodation by the local authority.—Mr. GRAHAM MURRAY replied: The hospital accommodation for small-pox in Greenock has been extended from time to time during the progress of the epidemic and steps are being taken for the erection of another additional pavilion. The circumstances attending the occurrence of every case are reported to the Board and there is nothing in these reports to suggest that patients are prematurely discharged. The existing reception house is suitable for the purpose but has not been equal to the demands arising from the epidemic. The Board has called upon the local authority to provide additional accommodation. It understands that great difficulty is experienced in acquiring proper premises.

Whisky Blending.

Mr. BLACK asked the Secretary to the Board of Trade whether he was aware that revenue officials, with the knowledge that a false description was taking place, did not prevent grain and foreign spirits being mixed with malt whisky and labeled as pure malt whisky in warehouses under Government supervision, and, if so, whether he would state what steps he proposed to take in the matter.—The CHANCELLOR of the EXCHEQUER replied: There are many reasons which make it undesirable to employ revenue officials in an attempt to regulate the trade descriptions that are placed upon goods in bond, the strongest of all being that any such regulation would be perfectly futile, as it would only result in postponing the application of descriptions until after the goods had passed out of bond and would afford no real protection to the public.

Portsmouth Lunatic Asylum Case.

Sir ALBERT ROLLIT asked the President of the Local Government Board whether he would state what steps would be taken to carry into effect the rider of the jury in the case of the inquest held on Feb. 25th upon the four female patients in Portsmouth Lunatic Asylum who died from the effects of careless dispensing, and whether the Local Government Board would cause regulations to be made requiring all dispensaries in public institutions to be in charge of persons registered under the Pharmacy Acts.—Mr. AKERS-DOUGLAS, who answered, said: There are several difficult points involved in this case and for the present I can only say that I am in communication with the Commissioners in Lunacy and that the matter shall be thoroughly considered.

TUESDAY, MARCH 8TH.

Royal Commission on Tuberculosis.

Mr. BATTY LANGLEY asked the President of the Local Government Board when the report of the Royal Commission on Tuberculosis would be available for members.—Mr. GRANT LAWSON replied: I understand that considerable progress has been made by the Royal Commission with its investigation but that the necessity for making the report as far as possible conclusive involves a very wide series of experiments. These experiments are being carried out on an extensive scale by the Commission and I am informed that it is impossible to state at present when the report will be issued.

In Praise of the Army Medical Department.

In the course of the general discussion on the Army Estimates Dr. FARQUHARSON made a reference to the condition of the Army Medical Department. He thought the House would learn with satisfaction that the department was now in an excellent state. Before the new regulations were introduced an examination was announced for which not a single candidate came forward, but he was informed that at the last examination there were nearly three times as many candidates as there were appointments to give away. It was equally gratifying that the men were all of the highest class and of great distinction in their education. Not only that but one or two of the examiners for promotion had stated that they had hardly ever known examination papers written with such ability. The army medical officers now got excellent pay and also "study leave" which would enable them to rub off the rust of foreign service by going to the centres of medical education and learning what had been happening in the civil world of medicine and surgery. There was only one word of warning. The arrangement of the department was excellent as it stood but he earnestly hoped that no attempt would be made to interfere with its success by the imposition of restrictions or by any other unnecessary interference.

Notes, Short Comments, and Answers to Correspondents.

"DR. HETHERINGTON, AMERICA."

WE have received the handbill of a person who trades under the above description. Hetherington evidently does not believe in the old Scottish proverb, "Hawks dinna pyke oot hawks e'en," for he says unkind things about other "American physicians" who are at the present day "advertising in British newspapers to treat all diseases by correspondence." In one point we agree with Hetherington when he says "that it is impossible to correctly form an opinion of diseases without seeing the patients," but nevertheless it is very easy to form a correct opinion of Hetherington without seeing him. His handbill is enough. In this cunningly worded document he informs the world that he is a doctor of medicine and dental surgery of the United States and is a qualified and registered dental surgeon of England. There is *no* such degree as doctor of medicine of the United States. With regard to Hetherington's dental qualification of England we have consulted the Dentists Register for 1903 and there is only one Hetherington therein whose qualification for being on the Register is that he was in practice before 1878. If this Hetherington and Dr. Hetherington of America be the same person we recommend the handbills to the notice of the General Medical Council. If they are not the same person we advise the Mr. Hetherington on the Register to disclaim any connexion with Dr. Hetherington of America. The latter gentleman has at least one element of success—he believes in himself; for we *note* that he describes himself as "the most skilful specialist in England or America for the speedy and pleasant cure of nervous, blood, and urinary diseases"—a modest estimate which reminds us of Gilbert's M. Pierre—

"He was the bravest man in France;
He said so—and he ought to know."

PROFITABLE POTATOES.

THE potato takes an important place among the foods furnished us by the vegetable kingdom and the prices which have recently been paid for specimens remind us of the excitement which prevailed in the seventeenth century when famous tulip bulbs were put up for sale. The *Profitable Farm and Garden*, a periodical the object of which is revealed by its title, on Feb. 27th devoted a special number entirely to the potato and its cultivation, a coloured plate of "Eldorado," the newest of the potatoes which have caused a sensation in the market gardening world, being issued as a supplement. When the disease-resisting "Northern Star" was placed upon the market, we learn from one of the articles in the special number, 10*s.* a pound was considered rather an exorbitant price to pay for the common tuber of our dinner tables, but so keen has been the demand for a tuber which would resist disease that £100 were willingly paid for 16 ounces of "Eldorado" when its merits became known. It is expected that should the present year's crop of this variety turn out well £3 3*s.* per pound will be asked for the tuber next winter. The special number contains many interesting articles upon potatoes, for example, "How to Propagate Potatoes," "Potato Pests," "The Best Potatoes," "How to Cook Potatoes," "Field Culture," "Potato Manures," "Culture in Germany," "Storing," and "Potato Implements." Is it not an astonishing thing that we nearly all of us eat potatoes every day and yet we do not see a well-cooked potato once a month? The publishers of the *Profitable Farm and Garden* are Messrs. Collingridge, 148-9, Aldersgate-street, London, and the price is 1*d.*

URETHRAL INJECTIONS OF CHLORIDE OF ZINC.

Surgeon writes:—Can any reader kindly say where *detailed* accounts of injuries to the urethral mucous tract caused by solutions of chloride of zinc may be found and the treatment of such injuries and the results, and also if any *experiments* have been made on the mucous membranes of the lower animals with solutions of chloride of zinc of *various* strengths and with what results?

THE PROPER FEE?

To the Editors of THE LANCET.

SIRS,—I have been asked to undertake the medical duties attached to a new convent home for the reception of epileptic children. The home is built to accommodate from 50 to 60 patients and when full the staff of nuns will bring the numbers up to about 80. I am distant about three miles and the house is *not* situated on the main road. It is proposed that I should make two regular visits a week—any visits beyond the bi-weekly ones to be paid for separately. Drugs and a qualified dispenser will be found. My object in writing is to ask if any of your readers will help me by suggesting what would be a fair *annual* payment for the regular visits and what sum should be charged for any extra visits that may be necessary. I may add that I am two or three miles nearer than any other practitioner and though the home is in my district it is quite out of my daily beat. Thanking you in anticipation,

I am, Sirs, yours faithfully,
W. B.

March 5th, 1904.

A CIRCULAR TRAVEL TICKET FOR LONDON STUDENTS.

Actum writes to us as follows:—

> I am a student but with my examination a long way behind me. When I can spare the time I listen, for example, to lectures at the National Hospital in Queen-square, at University College, London, at the Brompton Hospital for Consumption, and at other places. There I see crowds of senior students, alert, intelligent men and women. Would it not save much of their time and some expense to have for one fee a circular travel ticket about London? He or she would get into omnibus, or train, or tram, or tube, without other ticket or payment. When King's College Hospital is moved south of the Thames, and when the combined science schools are established, there will be the more call for facility of communication. Very simple rules would suffice to prevent abuse.

We quite agree that such circular travel tickets would be a great boon to the students in question and to many others besides medical and scientific students. The possibility of their issue merely depends upon whether the many companies concerned can see any profit for themselves in such an undertaking. It seems to us that to allot out of the inclusive fare the proportion which should belong to the main railway, the district railway, the omnibus, and the tram when the travellers live in all parts of London and attend demonstrations in all other parts would be far from a simple matter.

COTTON FACTORY DANGERS.

AT the hearing of a charge against a firm of spinners at Ashton of having "unfenced middle scrolls on spinning mules" a sensation was caused by the appearance of four boys, each without a right arm. These boys, who had all lost the right arm through accidents in unfenced middle scrolls, had been brought by Mr. Crabtree, the inspector of factories, from Oldham, Shaw, and Ashton to convince the court of the danger of this unfenced machinery. He said the beam of the engine had no fence and the engineer passed round it six times a day, each time endangering his life. There were also other dangerous parts of the machinery unfenced. A fine of a few pounds was inflicted which would not be felt much by a wealthy firm. But though these cases show that there is still dangerous neglect in some instances things are better than in the manufacturing days gone by.

◆

Mr. D. K. Chatterjee.—We thank our correspondent for his good wishes and commendations. The omissions he points out in regard to our analytical notices are only apparent, not real. The vegetable extract to which he refers contained, as was shown, 8 53 per cent. of nitrogen which multiplied by the factor for proteid gives 53 73 per cent. In the analysis of lentil flour, which is also referred to, the difference except for about 2 per cent. of fat may be taken to be carbohydrate. The statements about the food value of milk proteid are based upon the relative amount of proteid nitrogen in the dry substance as against that in meat with its complement of water.

Miss A. H.—We have forwarded the letter.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Chelsea (2 P.M.), Middlesex ([illegible] M.), Soho-square (2 P.M.), Samaritan [illegible] Orthopædic (4 P.M.), (2 P.M.), Rc[illegible] London Gt. EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

Hunterian Lectures

ON

THE PATHOLOGY AND SURGERY OF CERTAIN DISEASES OF THE PANCREAS.

Delivered before the Royal College of Surgeons of England on March 7th 9th and 11th, 1904,

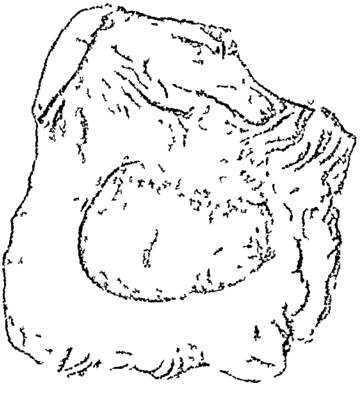
BY A W MAYO ROBSON, F R C S ENG,
HUNTERIAN PROFESSOR ROYAL COLLEGE OF SURGEONS OF ENGLAND

LECTURE I

Delivered on March 7th

[MR MAYO ROBSON commenced by referring to the comparative neglect which until quite recently was evidenced regarding the pancreas, its physiology and pathology He then passed on to consider the anatomical relations of the gland and their variations as influencing the etiology of its diseases or of the tissues with which it lies in relation He quoted a case described by J Symington[1] in which the duodenum was completely surrounded and constricted by a ring of pancreas Reference was also made to the invasion of the duodenum by new growths of the pancreas or the converse The pancreas may also be invaded by new growth or ulcer of the stomach, as seen in the illustration (Fig 1)

FIG 1



Chronic ulcer of the posterior wall of the stomach invading the pancreas (Fenwick, London Hospital Museum)

Mr Robson then gave an account of three cases under his own care in which chronic gastric ulcer associated with pancreatitis and abscess was cured by the performance of gastro-enterostomy In one case the ulcer was excised The lecturer then passed on to consider the anatomical relations of the pancreas and related the operative measures by which the gland may be exposed as to the peritoneum He then proceeded]

The ducts of the pancreas and their variations have important bearings on its pathology as have also the anatomical variations of the common bile duct. The chief excretory duct of the pancreas or duct of Wirsung after passing along the whole length of the pancreas, ends by joining the common bile duct in a small cavity called the ampulla of Vater, situated within the walls of the second part of the duodenum and the two ducts discharge their secretion together into the duodenum through the biliary papilla Besides this chief channel, the pancreas has an accessory duct the duct of Santorini, which opens through the papilla minor into the duodenum two or three centimetres above the papilla major These ducts present great varieties in their relations and in their course, and as we shall see when we come to consider the subject of inflammation, the anatomical variations are probably responsible for pancreatitis appearing in some cases of cholelithiasis and not in others First let us take the common bile duct, which may conveniently be divided into four portions—*a b, c, d* The first two for our present purpose are unimportant but the varieties of the pancreatic and the intraparietal portions are all important in the relations of jaundice to pancreatitis The common bile duct descends alongside the head of the pancreas and comes in contact with the duct of Wirsung, besides which it lies for a short distance before entering the intestinal wall According to Helly it is completely embraced by the head of the pancreas in 62 per cent and lies in a deep groove in the gland in the remaining cases It will be readily seen that if from any cause the head of the pancreas becomes swollen, say from an inflammation set up by the passage of a gall-stone or from a catarrh creeping up Wirsung s duct from the duodenum, the common bile-duct in the former variety will certainly be compressed and jaundice will follow, though in the latter variety where it only lies in a groove in the gland this compression may not take place and the patient may then escape jaundice

Compression of the common bile duct by the pancreas I believe accounts for many cases of so called catarrhal jaundice, both of the acute and chronic variety If under appropriate treatment the congestion or inflammation subsides the jaundice will rapidly pass off, but if the inflammation continues and chronic interstitial pancreatitis supervenes the jaundice will persist and with it a serious train of symptoms, which I hope to consider in my next lecture But this relation may act in another way, which can be seen exemplified in one of the specimens on the table and which we can reasonably infer must always occur in certain circumstances When a gall stone is passing down the common duct and succeeds in reaching the pancreatic portion of the duct it must, should the pancreas be embracing it, produce serious pressure on the gland which will lead to partial if not complete, obstruction of the pancreatic ducts, and thus to stagnation of the secretion in the pancreas, which will probably soon become infected either from the duodenum directly, through the already irritated duct of Santorini or by continuity of mucous surfaces through the duct of Wirsung where it opens into the ampulla of Vater, for it is well known that in many, if not all, cases of common duct cholelithiasis the bile becomes infected and we may reasonably argue from one to the other Thus this anatomical arrangement is probably responsible for many cases of pancreatitis of greater or less severity

It may be argued and, in fact, the argument is used in the text-books that if one duct of the pancreas be obstructed the other will take up its work, but this is not so in 50 per cent of cases, as shown by diagrams These diagrams are the result of the examination of 100 cadavers by Opie who found *that in more* than half of all individuals the duct is at its orifice obliterated or so contracted it cannot assume the functions of the larger is obstructed. The following statistics

FIG 2

Diagram to show the ampulla of Vater (A) with the ordinary termination of the common bile-duct (CD) and the duct of Wirsung (PD) (Testut) analysis. In 90 specimens the two ducts are united; in ten two wholly independent ducts enter the intestine. 1. Of the ducts in anastomosis. (1) Duct of Wirsung longer in 84: *(a)* duct of Santorini patent in 63; and *(b)* duct of Santorini not patent in 21. (2) Duct of Santorini longer in 6: *(a)* duct of Wirsung patent in 6; and *(b)* duct of Wirsung not patent, 0 2. Ducts not in anastomosis in 10: *(a)* duct of Wirsung longer in 5; and *(b)* duct of Santorini longer in 5. In 89 per cent. the duct of Wirsung was larger than the duct of Santorini. In 21 per cent. the duct of Santorini was apparently obliterated near its termination. In six cases the duct of Santorini was larger than the duct of Wirsung. In all cases where the duct of Santorini is patent it diminishes in size towards the duodenum. Thus the duct of Santorini cannot be relied on in many cases to supplement the duct of Wirsung, if it be obstructed; moreover, the duct of Wirsung, even if patent and communicating with the duodenum, may itself be compressed by a moderate sized gall-stone passing down the pancreatic portion of the common duct.

[1] Journal of Anatomy and Physiology 1885, vol xix, p 292.

The normal termination of the common bile-duct and of Wirsung's duct is into the ampulla of Vater (Fig. 2), which is a conical shell-shaped cavity into the base of which the ducts enter and which Testut describes as from six to seven millimetres in length, but this varies considerably in different individuals from 0 to 11 millimetres, the average according to Opie, in 100 bodies examined, being 3·9 millimetres. In only 30 did the diverticulum exceed 5 millimetres The orifice of the ampulla at the papilla is only 2·5 millimetres in diameter, it being thus narrower than any other part of the common bile-duct. In a proportion of cases the ampulla of Vater is absent, when the terminations of the common and pancreatic ducts are liable to great variations. There may be said to be four types as shown in the diagrams. First, the characteristic type which is described as the ampulla. In the second type the pancreatic duct joins the common duct some little distance from the duodenum, the ampulla is absent, and the duct opens into the duodenum by a small, flat, oval surface. In the third type the two ducts open into a smaller fossa in the wall of the duodenum, while the caruncle and the ampulla of Vater are both absent. In the fourth type the caruncle is well developed, the ampulla of Vater being absent, its two ducts opening side by side at the apex of the caruncle (Fig. 3). Among Opie's 100 cases there were 11 examples of this last type. If the diverticulum be large it is possible for a small stone to occlude the orifice and yet to leave the two channels entering the diverticulum patent, when bile passing down the common duct may be forced into the duct of Wirsung and bring on acute hæmorrhagic pancreatitis (Fig. 4). The diagram which I show illustrates the condition. I shall have more to say on this matter in another lecture when speaking of acute hæmorrhagic pancreatitis.

FIG. 3.

Accessory pancreatic nodules may be found by the side of, or within the duct of, Santorini or in the walls of the stomach, duodenum, jejunum, or ileum and in all such cases a small independent duct empties into the contiguous intestine An accessory pancreas has been found by J H Wright close to the umbilicus, it being apparently connected with the persistent remains of the vitelline duct. These may be of importance in serious diseases of the pancreas itself, as the histological characters and presumably the physiological functions conform to those of the normal pancreas. Thus may possibly be explained some cases where there is an absence of glycosuria in atrophy or extensive disease of the true pancreas. These accessory glands tend to undergo chronic interstitial inflammation and other diseases like the true pancreas, the inflammatory process being probably due to infection from the intestine into which the ducts open directly. In some cases these ducts have been found dilated and tortuous and in other cases narrowed close to their intestinal outlet.

Among the cases of accessory pancreas that have been recorded their association with intestinal, especially duodenal, diverticula has been noted. This anomaly is readily explained by the small accessory pancreas being developed in the muscular wall of the gut and producing a weak spot through which the mucous membrane tends to bulge. Among the anomalies of the pancreas, the head or tail may be found separated from the rest of the gland, or a portion of the head may be detached and lie behind the mesenteric vessels, or the groove from the mesenteric artery may be converted into a channel. In a case on which I operated recently I found a prolongation from the head of the pancreas extending upwards in front of the common bile-duct and the hepatic duct and exerting pressure on both owing to its being inflamed and swollen. A case of congenital ectopia of the head of the pancreas associated with gastroptosis was reported by Cacchini in 1886 and a number of cases have been reported in which the pancreas formed part of the contents of diaphragmatic and umbilical herniæ. In one case the pancreas was contained in the sac of a congenital umbilical hernia. A case of moveable pancreas producing symptoms resembling those of moveable kidney was reported by Dobrzycki in 1878; it was caused by a fall from a height in a man aged 56 years. In one reported case the pancreas was invaginated into the intestinal canal and, strange to say, there has been one case recorded where the pancreas was apparently entirely wanting.

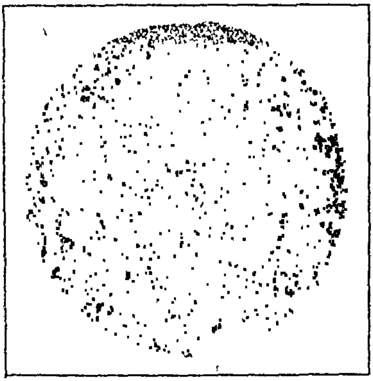
MINUTE ANATOMY.

The pancreas is a racemose or acino-tubular gland, the acini being formed of polygonal cells, the ducts connected with the alveoli being lined with flattened epithelium and the larger ducts with long columnar cells. It thus resembles the salivary glands in structure and it appears to have some obscure relation to these glands, as shown by metastasis from the one gland to the other in mumps. Lying in the interalveolar spaces are groups of small, irregular, polygonal cells known as the islands of Langerhans who described them in 1869 (Fig. 5). These cell masses have an important bearing on metabolism and, as we shall see shortly, on the glycogenic function of the pancreas, but as they are not connected with the ducts in the higher vertebrates they have apparently no relation with the proper secretion of the pancreas, though this is not finally settled. Like the salivary glands the pancreas has a firm texture, the lobes being large. The interacinar connective tissue is, however, of loose texture and readily allows of separation of the lobules, as shown in the beautiful specimen on the table from the Hunterian Museum. We shall see what an important bearing this tissue has when we come to consider interstitial pancreatitis.

Physiological considerations and their bearing on the pathology of the pancreas.—The ferments contained in the pancreatic juice, the proper secretion of the gland, are four: (1) trypsin, a proteolytic, proteid-digesting ferment; (2) amylopsin, an amylolytic or starch-digesting ferment; (3) steapsin a lipolytic or fat-splitting ferment; and (4) a milk curdling ferment. Besides these, which pass into the duodenum to perform their functions and which we shall see afford us certain signs in the excretions if they are absent, there is presumed to be an internal secretion, probably a ferment, secreted by the islands of Langerhans and passing into the blood. This may be termed a glycolytic ferment and when it fails, as occurs in certain inflammatory and other conditions, one of the results is glycosuria.

FIG. 5.



Micro-photograph of normal pancreas showing islands of Langerhans.

[Mr. Mayo Robson then recounted the nervous, vascular, and lymphatic supply of the pancreas in their bearing on the pathology of the gland, and continued:—]

Symptomatology and pathology.—As our knowledge of the functions of the pancreas, both with regard to digestion and metabolism, is becoming fairly well established it would seem probable that any departure from the normal would lead to such considerable disturbance of function that the symptomatology of any of the diseases of the pancreas would be so marked as to make the diagnosis easy. But this is far from being the case for several reasons: First, it is seldom the case that the pancreas is diseased without other organs participating—e.g., the relations between cholelithiasis and pancreatitis; between gastro-intestinal catarrh and catarrh of the bile and the pancreatic ducts; between ulcer or tumour of the stomach and extension to the pancreas; between affections of the liver, colon, lymphatic glands, and duodenum and pancreatic disease. Secondly, every function performed by the pancreas may be vicariously taken up by another organ, except the glycogenic function, and that we are not yet certain about. The stomach can digest albumin, the salivary and intestinal glands have the power of digesting starches, and the bile and intestinal secretions can emulsify fats. Thirdly, a considerable portion of the gland may be necrosed and cast off or otherwise disabled and yet the portion remaining may apparently be sufficient to carry on the functions of the pancreas. For instance, in a case of my own, a patient, who is now perfectly well, had necrosis of the pancreas which I removed at operation. As may be seen, a good proportion of his pancreas is on this table. Fourthly, in some cases the true cause of the disease may lie in the pancreas and yet all the symptoms may be caused by implication of another organ. For instance, cancer of the head of the pancreas produces intense jaundice and distension of the gall-bladder, giving the appearance to the uninitiated of disease of the liver or bile-ducts, a symptom to which I drew attention in a paper at the London Clinical Society in 1889. Again, a tumour of the pancreas may compress the intestine and produce intestinal obstruction or lead to pressure on the neighbouring ganglia and cause most violent pain that may be referred to spinal disease, to aneurysm, or to anything but the real cause. Thus it will be seen that very conflicting combinations of symptoms may arise and lead to great difficulty in diagnosis unless we can find some definite signs that will help us to say whether or no the pancreas is participating in the disease in question. I hope to show that this may be possible.

I have decided, before describing any of the special diseases of the pancreas, to consider certain symptoms apart, and as they are intimately associated with pathological questions, it is more convenient to take symptomatology and pathology together. The symptoms may be conveniently classified under (1) digestive symptoms; (2) physical signs; (3) metabolic symptoms; and (4) symptoms artificially produced. 1. Digestive symptoms: (*a*) steatorrhœa or fatty stools; (*b*) azotorrhœa or faulty digestion of albuminous foods; (*c*) sialorrhœa; (*d*) diarrhœa; (*e*) dyspeptic disturbances; (*f*) emaciation; and (*g*) nausea and vomiting. 2. Physical signs: (*a*) presence of swelling or tumour; (*b*) fever; (*c*) pain and tenderness with muscular resistance; (*d*) pressure on adjacent organs; (*e*) hæmorrhage; and (*f*) jaundice; 3. Metabolic symptoms: (*a*) glycosuria; and (*b*) other urinary changes. 4. Special symptoms obtained by artificial means: (*a*) alimentary glycosuria; and (*b*) Sahli's symptoms.

DIGESTIVE SYMPTOMS.

Steatorrhœa or fatty stools.—Although Claude Bernard, from experiments which caused the degeneration of the pancreas, came to the conclusion that the pancreatic juice caused the cleavage and emulsification of neutral fats and aided the absorption of fats in the intestine, yet the fact that the cleavage and the emulsification of fats are performed also by the bile, the intestinal juices, and the bacteria in the intestinal canal shows that the symptoms of steatorrhœa cannot be absolutely relied on in pancreatic disease. Abelmann's and Minkowski's observations on dogs are most important and interesting and they have been confirmed by Sandmeyer, Cavazzani, Balli, and Rosenberg When the pancreas was entirely removed non emulsified fat was not at all absorbed, and emulsified fat only in small amount (18·5 per cent.) The absorption of fat in the form of milk was much more favourable; on the administration of large amounts 30 per per cent., were absorbed. amounts of emulsified fat administration of larger amounts, 70 to 150 grammes, the consumption was not so good (lowest value 30 5 per cent.). Milk was very well absorbed, up to 80 per cent. Administration of pig's pancreas as food facilitated the absorption of fat after the extirpation of the pancreas. Abelmann concludes that all fat with the exception of milk needs unquestionably the influence of the pancreas for its absorption.

In clinical observations as to fatty stools many of the older clinicians relied on naked-eye observations which we now know to be fallacious; for though in some cases where fat is parted with in abundance it is manifest to the patient himself, in other cases a large amount of fat may be passed and only found on chemical investigation of the stools. Kuntzmann in 1820 and Bright in 1833 associated fatty stools with pancreatic disease. To show that the matter is not quite simple, Friedrich Müller found fatty stools in the absence of pancreatic disease, and in a case of obstruction of Wirsung's duct by calculus the fat in the motions was normal, though the last observation does not necessarily carry much weight as Santorini's duct may have been patent. It will be seen that experiments on animals and clinical observations on man do not altogether harmonise. We may, however, derive assistance in the diagnosis of pancreatic disease if we bear in mind the following conclusions:—1. Fat occurs in the stools in three forms: (*a*) as fat droplets; (*b*) as fatty acid crystals; and (*c*) as soap crystals. 2. The capacity for digestion and absorption of fats is limited; if therefore fat be taken in large quantities it is found in the stools. 3. Steatorrhœa occurs in some cases of jaundice, in some cases of enteritis, and in some affections of the pancreas, but in none of these constantly. 4. When jaundice and interstitial pancreatitis coexist there is a great excess of fat in the stools. 5. The presence of an excess of fat in the motions in the absence of jaundice and diseases of the intestine is suggestive of pancreatic disease. 6. If the pancreatic reaction (to be described later) be found in the urine along with steatorrhœa some affection of the pancreas is almost certain. 7. If azotorrhœa be found along with steatorrhœa it is almost certain that the pancreas is diseased, and if the pancreatic reaction in the urine, diabetes, and an epigastric tumour be present the diagnosis is certain.

The following case is reported by Oser. A woman, aged 39 years, had had diarrhœa since the summer of 1892. The patient became emaciated yet the appetite remained good. Fæcal evacuations appeared regularly every night, were unusually copious, of the consistency of thick porridge and of cadaverous odour, chocolate-coloured, and always abundantly covered with fat rings On Jan. 11th, 1893, he saw the patient for the first time and found steatorrhœa. The investigations of the stools gave the following result: large in amount and of the consistency of thick porridge; in the sediment were scattered white particles. Microscopic examination showed: (1) very numerous fragments of striated muscle in the main with well-preserved structure; (2) numerous fat acid needles and fat drops; and (3) bacteria and detritus. After drying the stools for several days on the water-bath in order to determine the amount of fat there were obtained 4 6325 grammes of solid substance, in which 2·1265 grammes were fat, representing 45·8 per cent. of the dried residue. The ether extract consisted almost entirely of neutral fat. On Jan. 18th he found in the epigastrium a distinct, hard, round tumour which was diagnosed as carcinoma of the head of the pancreas. In March jaundice developed. At the beginning of April an exploratory laparotomy was undertaken and the diagnosis confirmed. My own experience in a large number of pancreatic cases that have come under my observation has been the almost universal presence of an increased amount of fat in the motions, either in the shape of oily particles or of solid fat or of fatty crystals, which, if normal, should not contain more than 5 per cent.

The characteristic white stools that are often seen in pancreatic disease in the absence of jaundice owe their pale colour entirely to the solidification of the fat when the motions cool, although there may be a normal amount of bile present, and the greasy bulky motions so often seen in pancreatic disease with or without jaundice are often coated with almost pure oil. This is frequently remarked on by patients as floating on the surface of the urine passed at the same time.

In disease of the pancreas, interference with the digestive functions will lead to steatorrhœa and I have often noted it in acute hæmorrhagic, necrotic, and suppurative pancreatitis, in calculus of the pancreas, in cancer, and in some cases of cyst, where jaundice had accompanied the cyst formation. I have also seen an almost entire disappearance of the fat in some of these cases after the administration of pankreon tablets, liquor pancreaticus and sandwiches of raw pancreas, as well as a complete disappearance in many cases after surgical treatment.

Azotorrhœa or faulty digestion of albuminous foods.—Fles, so far back as 1864, found in the stools of a diabetic very numerous unchanged bundles of striated muscle fibres which disappeared when the patient had a calf's pancreas administered daily and reappeared when it was omitted. In dogs without a pancreas Abelmann found that albuminous substances were absorbed to the extent of about 44 per cent, and in those where the obliteration was incomplete 54 per cent. was absorbed. When pig's pancreas was given with the meats the amounts absorbed were respectively 74 and 78 per cent. De Benzi, Cavazzini, Sandmeyer, Rosenberg, and others found similar results. The conclusions we may form concerning this symptom are: 1. The digestion of nitrogenous foods is not solely the function of the pancreas. 2. As the normal stools of meat eaters contain a small proportion of undigested muscle fibres and as in febrile conditions, in disorders of the stomach, and in enteritis they may be found in excess, their presence in the motions is no proof of disease of the pancreas. 3 If azotorrhœa be found along with liporrhœa the presence of pancreatic disease should be suspected. 4 If azotorrhœa and liporrhœa be found associated with diabetes or with tumour of the epigastrium pancreatic disease is extremely probable. 5 If azotorrhœa and liporrhœa be found associated with the pancreatic reaction in the urine pancreatic disease is certainly present.

My experience of azotorrhœa is that it is not so readily noticed as steatorrhœa and my attention is hardly ever drawn to this symptom by the patient, though a careful naked-eye examination of the stools in nearly all diseases where the digestive properties of the pancreas are interfered with has shown the presence of muscular fibres and a microscopic examination has confirmed the observation. This, when taken with other symptoms, is an important point to notice.

Sialorrhœa pancreatica or excessive pancreatic secretion.—This has been referred to by Senn who suggested a causal relation between hyper-secretion of the pancreas and the diarrhœa which is sometimes [illegible] degeneration of the pancreas. Actual salivation has been noticed in the case of cysts reported by Ludolf and Battersby. Holzmann and others have reported the same symptoms in the case of pancreatic calculi which they explain as a reflex phenomenon. In the cholera epidemic in Bern in 1861 a large amount of leucin was found in the intestinal evacuations, suggestive of excessive action of the pancreas. Personally I have not seen salivation in any of my cases of pancreatic disease and I do not consider it of importance from a diagnostic point of view.

Diarrhœa pancreatica and alteration in the stools—In many cases I have mentioned what one might almost term a characteristic sign of pancreatic disease in the shape of exceedingly bulky, soft, greasy, pale motions, evidently due to the patient's want of digestive power and the passage onwards of the bulk of the food taken. These characteristic motions contain manifest unaltered fat and muscle fibre and are extremely offensive. Patients frequently describe them as diarrhœa, but an examination will show that this is usually an incorrect designation, the motions being bulky and soft and not liquid in consistency. They are due not only to the increased amount of fat and nitrogenous matter passing away undigested but to the bulk of hydro-carbonaceous food being parted with, sometimes unaltered. The symptom is a very noticeable one and when it occurs in cases of jaundice it may nearly always be taken as an indication that the pancreatic functions are being interfered with either by an interstitial pancreatitis or some other form of disease. I have more frequently noticed these symptoms in chronic inflammatory conditions than in cancer, the reason being that the appetite is more interfered with by the latter than by the former disease; hence also the symptom is more apt to be noticed in the earlier than the later stage of the disease unless large amounts of milk be given, when the bulk of it may pass away in this form of spurious diarrhœa. Blood may be noticed in the motions occasionally but it is not a regular symptom until the hæmorrhagic tendency occurs later in the disease or unless there happens to be an ulcerating malignant growth present In some cases constipation exists, the motions being still very bulky and, as a rule, pale. Abscesses of the pancreas and pancreatic cysts have been known to rupture into the intestine and their characteristic contents have been found in the motions. I have personally seen this in one case and in another I have seen the characteristic matter vomited. A necrotic pancreas has been passed through the intestine and cases have been reported by Leichenstern and Minnich in which pancreatic calculi have been passed per anum.

In a paper on the Clinical Significance of Colourless Stools without Jaundice and their Connexion with Disease of the Pancreas, read before the Royal Medical and Chirurgical Society in 1889, Dr. T. J. Walker of Peterborough pointed out the fact that white motions might be indicative of pancreatic disease, although the bile salts are being discharged in the normal way. In discussing this subject a few weeks ago with Sir Lauder Brunton he directed my attention to a lecture in his work, "Disorders of Assimilation, Digestion, &c.," which was published in the *Edinburgh Medical Journal* for February, 1900, where he had referred to the subject of whiteness of the motions and in which lecture he made the following remarks: "The whiteness is due not to the absence of bile as one would expect but to the presence of undigested fat" He referred to a case which he had seen ten years before He said: "The motions were as white as arrowroot but were tougher than ordinary formed motions, so much so that instead of breaking into pieces they fell into a very peculiar shape They looked like a snake coiled up with the head projecting as if ready to strike An analysis of the fæces was made by Dr. Sidney Martin who found that the liver was doing its work and that the motions contained bile, although in small quantity. Biliverdin was present in an unaltered form, though only an indication of biliary acids could be obtained. The reason of the motions being so white was the fact that the milk was not digested and therefore it appeared in the motions." Sir Lauder Brunton goes on to say that want of change in the fat points to some extent to alteration in the pancreas.

Dyspepsia and alteration of appetite.—I have found dyspeptic disturbances to be constantly associated with affections of the pancreas; they take the form of anorexia, pain and fulness after food, flatulency with offensive eructations, heart-burn, nausea, distaste for fats and for meat.

In the case of a woman, aged 28 years, to be referred to later under "Chronic Pancreatitis," a biliary fistula was established in order to relieve the jaundice and by drainage to cure the pancreatitis that was causing [illegible] oned [illegible] and [illegible] such [illegible] A cholecystenterostomy was performed and within 12 hours of the restoration of the bile and pancreatic fluid to the duodenum she expressed herself as hungry, a sensation which she said she had *not felt for many months; during* the month after operation she put on flesh very rapidly and three months later had gained two stones in weight. In several cases where dyspeptic disturbances have been well-marked both in simple and in malignant disease of the pancreas I have found the patients to be markedly relieved of their symptoms and to gain weight by the administration of pankreon tablets or of liquor pancreaticus immediately after meals.

Emaciation.—Ever since pancreatic diseases have been recognised, emaciation has been regarded as a well-known symptom. I have known a patient, a man, aged 59 years, suffering from chronic pancreatitis, to lose eight stones in a little over two years and to regain weight rapidly after a choledochotomy and the removal of a calculus that was obstructing the pancreatic duct, and I also know of another case in which the patient lost five stones in three months and after operation and relief of the condition to gain three stones in a corresponding period. It is not surprising that emaciation should occur in cancer of the pancreas, in which indeed it is most marked, or in diabetes of pancreatic origin, but it may occur in cystic disease, as in Kuster's case, in which the patient lost two stones five pounds in four months, in chronic pancreatitis, as in the cases I have mentioned, and also in calculous disease.

The disturbance of digestion may afford a sufficient explanation in some cases, but in the malignant and in the atrophic cases the interference with the metabolic function of the pancreas must also be partly responsible for the rapid emaciation. Alone, emaciation would not of course justify a diagnosis of pancreatic disease, but if with rapid loss of flesh, fat and muscle fibres be found in the fæces and pancreatic crystals in the urine the diagnosis of disease of the pancreas may be confidently made.

Nausea and vomiting.—These symptoms are frequently associated with acute pancreatitis and I have seen the vomiting so violent as to suggest acute intestinal obstruction, but in the other forms of pancreatic disease it is not a common symptom and when present it is often due to the neighbouring organs—stomach or duodenum—participating in the trouble or being pressed on. There is nothing specially characteristic in the vomited matter unless, as occurred in one of my cases, extremely offensive pus and altered blood be vomited, *when it may point to the rupture of* a pancreatic abscess into the stomach. In acute pancreatitis altered blood, so called "black vomit," is seen at an earlier stage than in any other peritoneal condition.

PHYSICAL SIGNS.

Tumour.—The situation of the pancreas behind the stomach and in front of the spinal column places it in almost the worst possible place for palpation, and in normal circumstances, if the patient be at all stout, it can only be indistinctly felt, but where the patient is thin and in cases of gastroptosis it can readily be defined when the muscles are relaxed and a warm flat hand is applied firmly to the epigastric region. It is commonly stated in text-books that acute and chronic inflammation and even abscess rarely, if ever, cause a perceptible enlargement of the organ. In this view I do not agree, for I have over and over again felt enlargement of the pancreas in these conditions, and I think further experience will show that in many cases a distinct swelling may be felt, which in the acute cases is made up of the swollen pancreas with surrounding effusion of blood and inflammatory fluid, together with matted omentum, in the subacute cases it being due to suppuration and in the chronic cases to a tumefaction of the gland itself. In cancer of the head of the pancreas the only tumour that is ordinarily felt is the swelling caused by an enlarged gall-bladder which can be readily palpated in a considerable proportion of cases. In tumour of the body or tail, as well as in some cases of cancer or sarcoma of the head *of the pancreas, palpation readily discovers the swelling,* and by distending the stomach with gas, either by means of carbonate of soda and *tartaric acid given in separate doses* or by pumping in air through the stomach tube, the relation of the stomach to the tumour can be readily made out. Resonance on percussion owing to the position of the stomach, unless the stomach is empty, communicated non-expansile pulsation, and very slight movement on deep inspiration are characteristic of swellings of the pancreas. In cystic disease of the pancreas tumour is at first frequently the only symptom, the position, as I shall hope to show, depending on the part of the organ from *which the cyst springs. It will thus be seen that the* absence of a tumour does not negative serious disease of the pancreas, though the presence of a swelling when taken with other symptoms, especially the urine test, affords valuable evidence of disease.

Fever.—An increase of temperature is, as a rule, associated with acute and subacute pancreatitis, but only rarely with any of the more chronic forms of inflammation, and as a rule it is absent in cystic disease, in calculus, and in new growths. In acute pancreatitis the temperature may be high but in other cases, as in the hæmorrhagic form, it is usually subnormal. In suppurative pancreatitis I have seen the temperature assume a hectic form but in one case coming under my notice it was subnormal and in another it was persistently from 101° F. to 102° or 103° and associated with rigors. In cancer of the head of the pancreas the temperature is generally subnormal. It will thus be seen that fever as a symptom is extremely variable and alone is no guide, though when associated with digestive, metabolic, and certain physical signs it is a symptom of the greatest importance in making a differential diagnosis.

Pain and tenderness.—These symptoms, though important when present, are so variable that even the entire absence of pain and tenderness is no proof that the pancreas is normal. My experience has been that both pain and tenderness are as a rule absent in malignant disease of the head of the pancreas, though, on the other hand, in some exceptional cases of cancer or sarcoma both of the head, body, and tail of the pancreas the pain may be excruciating, this depending either on pressure on, or involvement of, the great sympathetic *ganglia, or on pressure on, or invasion of, the* neighbouring viscera, especially the stomach or the duodenum. Small scirrhus tumours are as a rule characterised by the absence of pain while large growths are often marked by constant and extreme agony. In the various forms of pancreatitis pain and tenderness in the epigastrium are, as a rule, well marked and the more acute inflammations are characterised by excessive tenderness on pressure, rigidity of the recti, and pain of an agonising character. In chronic pancreatitis pain and tenderness, though usually present, may be little marked, but in some cases the pain is paroxysmal and severe and epigastric tenderness is well pronounced. Cysts may be quite painless and free from tenderness but in some cases I have seen both pain and tenderness well marked. Even in abscess of the pancreas pain may be absent, as has been reported by Stibler, though in the cases that I have seen pain and tenderness were both pronounced.

Calculus of the pancreas may exist for years undetected and unsuspected without causing any pain but in one case that I operated on the patient pointed to a tender and painful spot on the left of the middle line which she begged of me before operation to examine specially and at which exact spot I found and removed by operation a pancreatic [illegible] the orifice of the pancreatic [illegible] ater severe pain occurs in [illegible] seizure and will then be [illegible] *he character of the pain it* may be *continuous or paroxysmal* and *may* be limited to the epigastrium or radiate round either side of the thorax. I have found pain in the back, under the left scapula or between the scapulæ, to be more frequent than pain beneath the right scapula thus serving to distinguish it from gall-bladder pain. "Cœliac neuralgia" was a term long ago applied to epigastric pain such as is associated with some forms of pancreatic *disease and such pain may pass* to the cardiac region and resemble angina pectoris both in its intensity and in its effect on the circulation. It will thus be seen that while pain is a guide to diagnosis it is not pathognomonic of any special disease except acute pancreatitis.

Pressure symptoms.—The presence of ascites owing to involvement of the portal vein *is seen at times in the later* stages of cancer of the pancreas, when at the same time there may be also pressure on the inferior vena cava and œdema of the lower limbs. When the duodenum is surrounded by the head of the pancreas, an extremely rare condition, or where the gland partly surrounds the bowel, any growth or even inflammation of the head of the pancreas may lead to obstruction to the passage of the stomach contents, to gastric dilatation, and to vomiting, as in pyloric stenosis. Specimens which I will now show on the screen demonstrate how the stomach, the duodenum, and the colon may be pressed on both by cysts and new growths, such as cancer or sarcoma, and how the viscera contiguous to the pancreas may be seriously displaced, the stomach, for instance, being pushed upwards beneath the diaphragm or downwards below the umbilicus. Distension of the gall-bladder and jaundice are so frequently found in cancer of the head of the pancreas that they have become a well-known sign of the disease and in some cases of chronic pancreatitis the same sequence of events may occur, the presence or absence of this sign being dependent on the relation of the common duct to the head of the pancreas Pressure on, or involvement of, the solar plexus may give rise to agonising pain. In some cases the hepatic duct may be pressed on when the common duct is free, as in a case I saw a few months ago where there was jaundice without distended gall-bladder owing to pancreatitis involving a prolongation of the gland upwards towards the liver. The pressure of a pancreatic cyst passing upwards to the under surface of the diaphragm may cause dyspnœa from interference with the functions of the heart or the lungs, and in case of inflammatory effusion in the lesser peritoneal sac there may be pressure on the pericardium through the diaphragm leading to distressing cardiac symptoms.

Hæmorrhage.—Besides the local hæmorrhage that may be known as pancreatic apoplexy and the form known as hæmorrhagic pancreatitis, there is in many pancreatic affections a tendency to general hæmorrhage from wounds or from mucous surfaces and to petechial hæmorrhage in the skin or to more extensive bleeding in the subcutaneous tissues. It is well recognised that a hæmorrhagic condition coexists with cancer of the head of the pancreas. Some years ago I thought this to be altogether dependent on the cholæmia, until increased experience in operating on deeply jaundiced patients has taught me that there is much less danger of serious hæmorrhage in patients jaundiced from gall-stones than in those where the jaundice depends on pancreatic disease. This tendency may be due to an altered condition of the blood both in its tissue elements and chemically. In the cases where the blood has been examined for me a very marked diminution in the number of blood plates has been found and the coagulating period has always been seriously delayed.

As for the chemical changes, it is well known that a diminution in the lime salts leads to a tendency to hæmorrhage, and as we have found that there is in nearly every case of pancreatitis a profuse excretion of lime in the shape of oxalates this gives another explanation and also explains the beneficial effects resulting from the administration of calcium chloride. In urine containing bile, calcium oxalate crystals are not generally found microscopically because the bile takes up the lime salts, but after the jaundice has been relieved by operation an examination of the urine will, as a rule, show oxalate crystals so long as any pancreatic trouble continues. In several cases of cancer of the pancreas on which I have operated the bleeding has been the immediate cause of death. In one case sent to me in 1888 by Professor T. Clifford Allbutt, a cholecystotomy was followed by persistent oozing of blood from the interior of the gall-bladder and from the stitch punctures, which resisted all the then known remedial measures in the way of styptics, pressure, transfusion, &c., and proved fatal on the ninth day. In another case of cancer of the head of the pancreas, sent to me by Dr. W. Scatterty of Keighley, a cerebral hæmorrhage on the tenth day produced a fatal result. In neither of these cases was there any peritonitis or other cause than the hæmorrhage to account for death Now in another patient equally deeply jaundiced whom I saw with Dr. T. Churton in 1889, but where the disease was dependent on cancer of the common bile-duct above the entrance of the pancreatic duct, there was no hæmorrhage, although the patient survived several weeks and died from exhaustion due to the disease and to the suppurative cholangitis accompanying it. I could give many similar comparisons showing the difference between the behaviour of the blood in the two classes of cases.

Before operating on these cases I now always administer calcium chloride in from 30 to 60 grain doses thrice daily for from 24 to 48 hours previously to operation and by enema in 60 grain doses thrice daily for 48 hours afterwards; this is usually successful in correcting the hæmorrhagic tendency. The following cases show its efficiency subsequently to operation.

A woman, aged 38 years, was suffering from deep jaundice associated with gall-stones in the common duct and chronic pancreatitis. There was no bleeding at the time of the performance of duodeno-choledochotomy as calcium chloride had been administered for several days before operation. The drug was inadvertently omitted after operation and on the third day violent hæmorrhage occurred which was arrested by opening up the wound and packing with gauze and at the same time giving calcium chloride in 60 grain doses twice and afterwards in 30-grain doses for several days. No recurrence of bleeding occurred and a good recovery was made.

In the case of a male patient, aged 42 years, suffering from cirrhosis of the liver, gall-stones in the common duct, and chronic pancreatitis, no bleeding occurred at operation owing to the saturation of the blood with lime salts; in consequence of this they were left off the second day after operation. Bleeding occurred very freely on the sixth day in the form of general oozing which was permanently arrested by the free administration of calcium chloride, after which recovery occurred.

In a case of suppurative catarrh of the pancreas in a gentleman, aged 65 years, the same freedom from hæmorrhage was found at operation after the administration for some days of chloride of lime which could not be given as the rectum was intolerant of injection. On the seventh day free bleeding occurred which was arrested by giving 30 grains of calcium chloride every two hours.

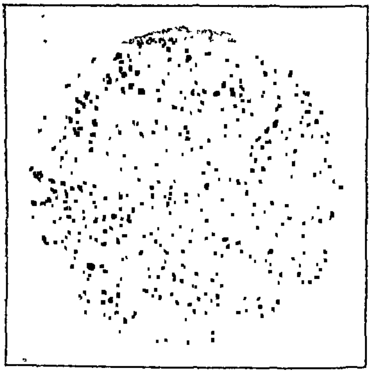
Other cases could be given were it desirable to show the remarkable effect of saturating the blood with lime in order to prevent or to arrest bleeding in these cases. In operating on these cases of pancreatic trouble, especially if associated with jaundice, it is important carefully to ligature all vessels and not to trust to simple forci-pressure.

Jaundice—The now well-recognised relation between pancreatic and gall-stone trouble would lead one to suspect that jaundice would be a frequent accompaniment of pancreatic disease but this symptom is by no means constant. The relation of the common duct to Wirsung's duct and to the head of the pancreas is generally the determining factor of deep jaundice, though in nearly all inflammatory affections an extension of the inflammation takes place and sets up a more or less severe catarrhal jaundice. If, as is the case in 38 per cent. of bodies (Helly), the common duct passes behind the head of the pancreas either an acute or chronic pancreatitis, or even a cancer of the pancreas, may run its course without the appearance of jaundice, but if the common duct lies in a deep groove or is imbedded in the head of the pancreas, as occurs in 62 per cent. of cases, either pancreatitis or growth of the head of the pancreas must necessarily compress the bile-duct and lead to jaundice of greater or less intensity. It may, perhaps, only be a coincidence, but Dr. Cammidge tells me that in all the specimens of urine that he has examined for me from patients suffering from pancreatitis, bile has been found in just over 60 per cent. If common duct cholelithiasis be the cause of pancreatitis jaundice will, of course, be present. Deep jaundice associated with distended gall-bladder is significant of cancer of the head of the pancreas, whereas if the cause of the jaundice be gall-stones in the common duct the gall-bladder is nearly always contracted and not capable of being felt.

METABOLIC SYMPTOMS.

Diabetes and glycosuria as symptoms of disease of the pancreas.—In speaking of the functions of the pancreas mention was made of an internal secretion which recent researches have apparently traced to the islands of Langerhans. It is believed that the absence of this secretion owing to the destruction of these islands leads to diabetes. The earliest observations connecting the pancreas with diabetes was by Cowley in 1788 in the *London Medical Journal*. The patient was an alcoholic, 34 years of age, and a post-mortem examination showed the pancreas to contain numerous calculi. In 1821 Chopart reported the case of a diabetic, aged 19 years, who also had jaundice and steatorrhœa. A necropsy revealed the head of the pancreas to be forming a hard, nodular tumour and the body to be atrophied, [illegible] and Minkowski, [illegible] pancreas in dogs regularly resulted in diabetes, and the important discovery of Opie that hyaline degeneration of the islands of Langerhans was present in a girl, aged 17 years, who had died from diabetes, followed by other observations that diabetes is only present when the islands of Langerhans are involved as in the interacinar type of chronic interstitial pancreatitis, have now apparently established the fact that in diseases of these islands we have the origin of pancreatic diabetes. This explains many of the anomalies that were previously incapable of explanation and renders it quite easy to see why glycosuria should be present in some diseases of the pancreas and not in others. For instance, in chronic interstitial pancreatitis of the interlobular type there is no glycosuria, and the lantern slides which I now show, kindly made for me by Dr. P. J. Cammidge, demonstrate that in this condition the islands of Langerhans are quite free from disease (Fig. 6) In the next slide, one of chronic interstitial pancreatitis of the interacinar form, it will be seen that the islands of Langerhans are involved and in this case diabetes was found and led to death. The next slide is from a case of general cirrhosis of the pancreas with diabetes. Here it will be noticed that the atrophic process has involved the islands. The next slide shows hyaline degeneration of the islands of Langerhans where diabetes was present. This slide is copied by permission from Dr. Opie's monograph of a specimen which he was good enough to demonstrate to me in the Johns Hopkins Laboratory (Fig. 7). In extensive malignant disease the whole gland may be destroyed and then diabetes will be present, as in the photograph of a specimen which I show on the screen.

FIG. 6.



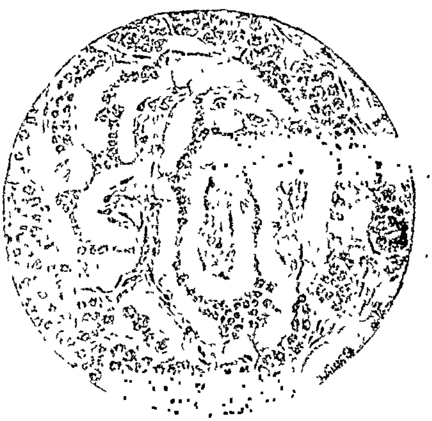
Micro photograph showing chronic interstitial pancreatitis of interacinar variety. From a case of diabetes.

In cases of cancer part of the gland may remain unaffected—glycosuria will not then be present, and the same applies to cysts and other tumours, as well as to interstitial pancreatitis, which may be limited to one part of the gland. Out of a large number of cases of disease of the pancreas that I have seen I have only occasionally found glycosuria present, and in such cases, if well marked, I have not recommended operation, though I am not prepared to say that benefit might not arise by drainage in some cases of interacinar pancreatitis if caught early. As yet, however, I have no experience to bring forward to prove this.

It will thus be seen that glycosuria is not common and cannot be relied on as a diagnostic symptom in diseases of the pancreas, but when it exists along with other signs it is extremely serious and, in fact, as a rule indicates an incurable condition.

Other changes in the urine.—In consequence of the indefinite character of the symptoms in various diseases of the pancreas a want has been long felt for some distinctive signs by which affections of the pancreas may be diagnosed. From the important metabolic functions of the gland attention was naturally given to the urine and in turn indicanuria, maltosuria, pentosuria, lipuria, and glycosuria have been advanced as of diagnostic importance in pancreatic troubles. With regard to indicanuria Gerhardi in 1886 from observations on man, and Piseni from experiments on dogs, thought that changes in the amount of indican in the urine afforded diagnostic data in pancreatic diseases, but Katz and De Renzi's experiments on animals disproved this, and many observations on my own cases and those by other clinical observers enable us to say that the amount of indican in the urine is no guide to the presence or absence of disease of the pancreas Le Nobel and von Ackeren separately found maltose or some allied sugar in two cases of pancreatic disease but in a large number of observations on the urine from patients suffering from different forms of pancreatic disease it has not been found. This, therefore, cannot be relied on as an important symptom. Pentosuria, according to Salkowski, is of greater diagnostic importance, but further observations showed it to be inconstant and to be present in other than pancreatic conditions. Lipuria is a rare condition and although described by Mr. Alfred Clark in THE LANCET of August 16th, 1851, p. 152, as having been associated with a case of cancer of the pancreas, it is known to result from divers causes. Of all the cases of pancreatic disease that I have seen I have only once found lipuria as a symptom and that was in a case of chronic pancreatitis in a lady, aged 44 years. It was associated with liporrhœa, azotorrhœa, bulky stools, and with a well marked pancreatic reaction in the urine, the cause being apparently an extension from duodenal catarrh. The abdomen was opened and a swelling of the pancreas was discovered with a number of adhesions surrounding it, but no gall stones were found. Drainage of the bile-ducts by a simple cholecystotomy completely cured the pancreatic condition, and when the urine was examined a year later there was an entire absence of the pancreatic reaction. Lipuria is difficult to explain and in the case I have mentioned it was not associated with any signs of diseased kidney. As it occurs so seldom it cannot be relied on as an important point in affections of the pancreas.

FIG 7.



Micro-photograph showing hyaline degeneration of the islands of Langerhans. (Opie)

As showing how little importance has been attached to urinary analysis as an aid to diagnosis Oser says: "In brief, the condition of the urine in diseases of the pancreas has no special peculiarities." I hope to be able to prove that this statement will i [illegible] of a large number of [illegible] of cases I hope, in [illegible] to be able to adduce proofs that a certain reaction may be obtained from the urine in the greater number of, if not in all, diseases of the pancreas, which affords considerable help in diagnosis, but further than this, our experience leads us to believe that it may be possible to distinguish between acute and chronic inflammation and between simple and malignant disease. The presence of glycosuria does not prevent the pancreatic reaction being obtained but the sugar must first be removed by fermentation. In this way, therefore, it may be possible to make the diagnosis of pancreatic diabetes. At first when the method was crude and incomplete and our experience in its employment was small, the conclusions, though helpful, were not so certain that one dare venture to assert more than a hope that it would be a help in diagnosis, and this I announced in an address before the American Surgical Association in Baltimore in May, 1901. From that time onwards the test has been applied in every case that has come under my care where the pancreas was suspected and in a large number of control cases where there was no suspicion of pancreatic disease. The control experiments led to the discovery that certain allied crystals were obtained in some other diseased conditions, such as cancer and chronic inflammation, where marked tissue changes were taking place, but fortunately the difference in the shape of the crystals and the increased time they took to dissolve in sulphuric acid and other tests enabled them to be differentiated. There is still a great deal of work to be done on the subject which may have other important issues but we think the time has come when a further announcement should be made so that the utility of the method may be tested by other observers. Of the manner in which these crystals were found, of the method of their preparation, and of their significance, my friend Dr. Cammidge will have much more to say in his Arris and Gale lecture; of their diagnostic importance I will now give my experience.

To give a list of all the cases that we have observed together would be easy, since all have been accurately recorded, but in this lecture it will be more useful if I group the cases. Although I have operated on over 100 patients for pancreatic disease of one kind or another, in my earlier cases the urinary pancreatic reaction was unknown and it is only during 1900 and since that we have been employing the test systematically, but during that time several hundred analyses have been made and the diagnoses have been confirmed by operation in 56 and by necropsy in other cases.

In a considerable number of cases of cancer of the head of the pancreas with jaundice the test has been applied and either confirmed the diagnosis made from the clinical signs or proved the presence of malignant disease in the face of irregular symptoms which rendered the diagnosis doubtful, so that one has been able to advise non-operative treatment with confidence instead of having to recommend an exploratory operation which could do no real good. One of the most marked cases of this kind occurred only a month ago where no less than six medical men of eminence had advised operation in a woman, aged 48 years, in consequence of the general condition of the patient being better than one might have expected after jaundice had existed for five months had the cause depended on cancer. An examination of the urine revealed such a marked pancreatic reaction pointing to cancer of the head of the pancreas that I had not the slightest hesitation in advising non-operative treatment. This, however, did not satisfy the patient who, with the support of her medical advisers, wished to have an exploratory operation done. On opening the abdomen I found, as suspected, a very hard, nodular growth of the head of the pancreas, undoubtedly malignant. The absence of adhesions and the presence of a distended gall-bladder afforded clear evidence that gall-stones had never been present in the case.

In several cases suspected from the clinical signs and symptoms to be cancer, the disease has been proved by this test to be inflammatory and curative operations have been performed—for instance, in the case of a man, aged 51 years, seen in August, 1901, suffering from deep jaundice with great emaciation, the liver being enlarged and there being very slight tenderness. Although he had had rigors and other signs of infective cholangitis there was no history of pain beyond one slight attack of colic that was very indefinite. Cancer of the pancreas had been diagnosed and his case was believed to be hopeless. Before refusing to operate an analysis of the urine was made and a well-marked pancreatic reaction was found, pointing to inflammation and not to malignant disease. An operation was therefore undertaken on Sept. 29th, 1901, when the head of the pancreas was found to be markedly enlarged, the swelling extending well into the body of the pancreas, and five calculi were found in the lower end of the common bile-duct obstructing the pancreatic ducts. These were removed and the common duct was drained. The patient made a good recovery and in two months had gained one stone three pounds. A report received last year was to the effect that he was in perfect health.

In another case that I saw in October, 1903, a patient, aged 57 years, who had resided in India for years, where he had suffered from fever which had left him with a greatly enlarged spleen, gave a history of loss of flesh for some months preceding the jaundice which came on in July, 1903. The patient himself said that he had had no pain but his medical man said that there had been an attack of pain preceding the jaundice. Loss of flesh was well marked and the patient was so ill, there being slight œdema of the feet and enlargement of the spleen to below the umbilicus and of the liver to the umbilical level, that I had very little doubt of the case being malignant. A consulting physician who saw him before me found ague organisms in the blood and after watching him for a time considered the case unsuitable for operation. Before deciding finally an examination of the urine was made, when a well-marked pancreatic reaction was found pointing to inflammation and not to malignant disease and an analysis of the fæces showed steatorrhœa and azotorrhœa. An operation was therefore performed on Nov. 5th, 1903, when the liver was found to be enlarged, dark, and granular, as if in the first stage of cirrhosis, and after separating numerous adhesions a rounded gall-stone of the size of a small walnut was discovered in the common duct, where it was pressing on the pancreas. The pancreas was considerably enlarged but it did not embrace the common duct. After the removal of the calculus a probe passed quite easily into the duodenum and as the duct was not embracing the pancreas I did not consider it necessary to drain it. Recovery was completely satisfactory and the patient is now well.

In one case diagnosed by an eminent physician as cancer of the head of the pancreas, that of a man, aged 65 years, no pancreatic reaction was obtained and on the strength of this test an exploratory operation was performed, when the pancreas was found to be healthy and a gall-stone was removed from the upper part of the common duct, with the result that the patient is now well. In two cases of malignant disease, "cancer of the head of the pancreas and cancer of the biliary papilla" with deep jaundice, the test showed the presence of inflammation of the pancreas and exploratory operations were in consequence undertaken, but the error was not in the test but in our reading of it. The fact is that in many cases of cancer of the pancreas a catarrhal inflammation ensues as a secondary symptom, just as a catarrhal jaundice frequently supervenes in cancer of the liver. These cases led to modifications in the process which have prevented further mistakes of the same nature. In two cases of pancreatic cyst where the diagnosis was doubtful the test showed the presence of pancreatitis which is usually present in the interstitial form in these cases. In three cases of acute pancreatitis the test answered perfectly in confirming the diagnosis. In two cases of suppurative catarrh, associated with fever and jaundice, the presence of pancreatic inflammation was proved by an abundant crop of crystals. In a number of cases of simple catarrhal and of interstitial pancreatitis, both with and without gall-stones, the pancreatic reaction has enabled a diagnosis to be made and active treatment to be applied. In two cases of abscess of the pancreas the reaction was well marked and proved to be correct at the operation and in two cases of pancreatic calculi the reaction proved the presence of interstitial inflammation. Almost equally important have been some of the negative reactions in chronic biliary catarrh, in cirrhosis of the liver, and in tumours supposed to be pancreatic from their situation behind the stomach. From a pathological and clinical point of view the observations made on the urine of patients long after being operated on for pancreatic inflammation and supposed to be quite well are most instructive and will be mentioned in my next lecture.

SPECIAL SYMPTOMS OBTAINED BY ARTIFICIAL MEANS.

Alimentary glycosuria.—Minkowski has shown that if only a part of the pancreas be removed diabetes does not result but the ability of the organ to perform its normal function on carbohydrate metabolism is impaired; for if to animals in which the pancreas has been partially removed sugar be given in large quantities temporary glycosuria results. Wille has observed the symptom in man in association with disease of the pancreas. He adopted the test of giving from two to three ounces of sugar before breakfast to 800 patients, the urine being tested before the sugar was taken and later at intervals of two hours When the test was positive glycosuria usually occurred at the end of two hours. Of 15 patients exhibiting alimentary glycosuria who subsequently came to necropsy, ten presented grave pancreatic disease, chronic interstitial pancreatitis or cancer. Although this symptom may occur under other conditions, as exophthalmic goitre or chronic alcoholism, its presence has considerable value as an aid to diagnosis.

Sahli's symptom.—If iodoform be inclosed in a gelatin capsule, hardened in formalin, and given by the mouth it is almost unaffected by gastric digestion but is readily dissolved by the pancreatic secretion. If pancreatic digestion is normal, iodine should appear in the urine in from four to eight hours. The absence of the reaction or its delayed appearance, if the motor function of the stomach be normal, indicates, according to Sahli, an impairment of pancreatic digestion.

GROUPING OF SYMPTOMS.

With such a number of symptoms and signs as those I have related it is a mystery to me how the idea has gained so firm a hold that pancreatic diseases are, as a rule, undiagnosable. For instance, Opie only last year wrote: "Disease of the pancreas is rarely recognised during life," which is a reproach that I hope will in future have no justification. Although in any single case we may not have all the symptoms and signs that I have mentioned, yet in no case ought we to fail to find digestive or metabolic or physical signs if disease of the pancreas be present. Different diseases of the pancreas it will be seen, as one would expect, present very various grouping of symptoms, but in nearly every, if not in every, case since Dr. Cammidge and I have been working together at the subject we have found most valuable help from the pancreatic reaction. Although we must not yet say that this sign is absolutely pathognomonic, yet it is safe to make the assertion that if the test be skilfully carried out it affords most valuable positive or negative evidence when taken with other symptoms, in not only establishing the presence or absence of some disease of the pancreas but in assisting in the differentiation of simple from malignant disease, a most important matter when surgical treatment is in question.

The two pathological conditions of fat necrosis and hæmorrhage are full of interest and to do full justice to them would occupy all the time at my disposal. Although they are intimately related to pancreatitis it is desirable that they should have separate consideration.

Fat necrosis.—Fat necrosis was first described by Balser in 1882, but has since been investigated by Langerhans, Hildebrand, Dettmer, Milisch, Williams, Flexner, Opie, and many others. Experiments by Opie, who ligatured the pancreatic ducts in the cat, go to show that widespread fat necrosis may be expected to follow the operation very rapidly. A photograph of this was shown on the screen and at the same time a microphotograph of fat necrosis.

By fat necrosis is understood a disintegration or necrosis of the living fatty tissues in the neighbourhood of the pancreas or in small spots diffused widely over the peritoneal cavity or even in the pericardium or pleura or subcutaneous fat. It is associated with a splitting up of the fat into fatty acids and glycerine; the latter is absorbed but the acids being insoluble remain in the cells either as crystals, or uniting with the calcium salts of the blood they form yellowish-white patches of various sizes. Fat necrosis is commonly found in association with pancreatitis and other diseases of the pancreas and the relation between the two conditions has given rise to much speculation. As the result, however, of clinical observation and experimental evidence we may now accept the fact that it is always the result of the penetration of the fat-splitting ferment of the pancreas first into the tissues in the neighbourhood of the gland and when more extensive to the diffusion of the ferment either through continuity of tissue or by means of the lymphatics. It is important to remember that fat necrosis may be present and yet not be visible to the naked eye, although it may be discovered by a method suggested by Bender, the application of a solution of acetate of copper to the tissues. The recognition of fat necrosis by the surgeon who opens the abdomen to relieve symptoms associated with peritonitis in the upper abdomen is of the utmost importance, as it indicates a grave lesion of the pancreas, probably hæmorrhagic, gangrenous, or suppurative pancreatitis It is said not to occur generally with suppurative inflammation, but in a case to be related shortly I found a most extensive fat necrosis in association with subdiaphragmatic abscess of pancreatic origin. It has also been said that the presence of extensive fat necrosis is a fatal sign, but a case of my own disproves this, as a patient under my care made a complete recovery after an operation undertaken for acute pancreatitis in which the fat necrosis was well marked and diffuse. Truhart has also been able to collect ten cases in which the diagnosis was made and yet an immediately fatal issue did not occur. As the ferment causing fat necrosis may be excreted by the kidneys it would form an important diagnostic sign if it could be found in the urine, but this has not yet been determined, although in one case of acute hæmorrhagic pancreatitis Opie obtained a suggestive reaction by means of ethyl butyrate, as suggested by Castle and Loevenhart.

Hæmorrhage.—Hæmorrhage in its various forms is often held up as one of the great mysteries of pancreatic affections and the free use of the term "hæmorrhagic pancreatitis" in ordinary acute inflammation, even where there has been really no hæmorrhage and in others no more bleeding into the tissues than takes place frequently in acute inflammation in other organs where the tissues are soft, has led to an accentuation of the mystery. It is well known that local hæmorrhage into the pancreas may occur apart from injury and apart from any general hæmorrhagic tendency and that, although it may be recovered from, as shown by the remains of extravasated blood in the gland in persons dying from other diseases, yet such spontaneous hæmorrhage may lead to death from collapse either immediately or after some hours Curiously this may occur in persons apparently in good health and without any premonitory signs on which a diagnosis can be based, the only symptom at the time being those of collapse, with dyspnœa and feeble pulse. In this way, severe pancreatic hæmorrhage apart from pancreatitis, forms a disease in itself.

CAUSES OF PANCREATIC HÆMORRHAGE.

1. Vascular disease, such as atheroma and fatty degeneration, or alcoholic or syphilitic arteritis. The following case under my care appears to be one in point. An aged subject, with markedly atheromatous vessels, had a simple drainage operation performed for the relief of jaundice due to cancer ot the head of the pancreas. Death occurred on the third day, almost suddenly from collapse, and at the necropsy there was found extensive effusion of blood away from the site of operation and behind the peritoneum, extending into the loins around the kidney and into the cellular tissues beneath the diaphragm, the blood being in sufficient quantity to account for death. The bleeding had manifestly arisen from the pancreas but there was no gross vascular lesion found to account for it.

The following case under the care of Draper (one of sudden death from pancreatic hæmorrhage) is reported by Oser. A woman, aged 44 years, was found dead in bed. She drank alcoholic liquors but was rarely intoxicated and in the evening before was perfectly well. In the morning she complained of headache, returned to bed, and later was found dead. At the necropsy the pancreas was seen to be infiltrated [illegible] its whole extent; there were also a [illegible] the retroperitoneal tissue and [illegible] the peritoneal cavity.

2. Injury may be the cause. The tissues of the pancreas are comparatively soft and easily bruised, so that although anatomically it is placed in the most protected position, yet a slight injury takes more effect on it than on many other firmer organs and there is ample experience of pancreatitis resulting from blows in the epigastrium apparently trifling in character as in a case that I saw several years ago. A butler slipped and fell forward against a knifeboard projecting from the end of the table at which he was working. The blow was comparatively slight and the man did not even fall to the ground. Pancreatitis followed on what was at the beginning probably a mere bruising of the pancreas but which was followed by slight bleeding into the gland and this effusion becoming infected acute hæmorrhagic pancreatitis resulted. An exploration for the cause of the peritonitis resulted in the discovery of a large collection of highly blood-stained fluid in the lesser peritoneal sac, some of

which had burst through a small laceration in the omentum into the greater peritoneal sac. There was general peritonitis present at the time of operation and though drainage was freely adopted both from the front and back the patient did not survive many hours. Probably slight injury to the pancreas may occur in abdominal operations for gall-stones in the common duct when it is sometimes necessary to manipulate the head of the pancreas rather freely. Though I have not personally seen such an occurrence, such a case has been related recently. The photographs now thrown on the screen are examples of hæmorrhagic pancreatitis and the specimens from St. Bartholomew's Hospital Museum on the table show traumatic hæmorrhage and hæmorrhagic pancreatitis respectively.

3. Fatty degeneration of the gland cells and deposit of fat in the pancreas, the result of alcoholism or of general adiposity, may lead to want of support of the blood vessels which are no longer able to withstand the blood pressure. This may account for hæmorrhagic pancreatitis so often occurring in fat and flabby individuals. I show on the screen a case of fatty pancreas from the Hunterian Museum.

4. Fat necrosis in the gland or its vicinity has been suggested by Balser who related several cases in support of his views.

5. Disintegration of neoplasms, such as cancer or sarcoma, may be the cause of extensive hæmorrhage.

6. Hæmorrhage from embolism of a pancreatic artery is reported by Mollière.

7. Other causes, such as heart disease, lung disease, cirrhosis of liver, hæmorrhagic diathesis, scurvy, purpura, the exanthemata, phosphorous poisoning, &c., may all give rise to pancreatic hæmorrhage.

8. Pancreatitis may undoubtedly lead to hæmorrhage and in considering acute pancreatitis I shall refer to it again, but it seems highly probable that an effusion of blood into the pancreas from one of the before-mentioned causes should more frequently be the cause rather than the effect of pancreatitis owing to disruption of the secreting tissue, escape of the proper secretion of the gland, fat necrosis, and invasion of the effusion by organisms either through the ducts or in some other way. Large pancreatic hæmorrhages are of great interest clinically and are probably more common than is usually thought; they may occur into the substance of the gland and disintegrate it, or on to the surface and lead to extensive effusion either beneath the peritoneum or into the lesser sac, as in the case which I have related.

Symptoms.—A great variety of symptoms may occur, from mere attacks of colic in the epigastric region, soon passing off, to violent and persistent pain followed by collapse and rapid death within a short time, or if recovery from the first seizure should occur the attacks may be repeated and ultimately symptoms of acute pancreatitis may supervene. The site of the pain may be præcordial or dorsal but it is usually epigastric and is often accompanied by vomiting. The abdomen soon becomes distended and tympanitic and if inflammation occurs fever of an irregular type may supervene, or if the disease assumes a rapid ultra-acute form the temperature may be subnormal throughout. At first the diagnosis will be obscure but with the onset of pancreatitis some of the symptoms which I have related will be found and an examination of the urine for the pancreatic reaction will afford valuable help.

Treatment.—In the very acute cases, where death rapidly occurs, even if the diagnosis could be made specific treatment would probably be useless, but if the diagnosis could be effected before a fatal result had occurred abdominal section and gauze packing would seem to be indicated. In the later stages the treatment is that of acute pancreatitis and in this case a diagnosis can be made both from the symptoms and physical signs as well as from the discovery of the pancreatic reaction in the urine.

ST. BARTHOLOMEW'S HOSPITAL REBUILDING SCHEME.—The March issue of the *St. Bartholomew's Hospital Journal* prints a list of old St. Bartholomew's men who have intimated their willingness to act as local secretaries for the purpose of raising a sum of money towards the rebuilding scheme. It is suggested that it would be appropriate if a new pathological department could be provided by the exertions of past and present students of the hospital and with this object a subscription list will be published monthly in the *St. Bartholomew's Hospital Journal.*

The Arris and Gale Lecture

ON

THE CHEMISTRY OF THE URINE IN DISEASES OF THE PANCREAS.[1]

Delivered before the Royal College of Surgeons of England on March 14th, 1904,

BY P. J. CAMMIDGE, M.B. LOND., M.R.C.S. ENG., D.P.H. CAMB.,

LATE COUNTY BACTERIOLOGIST, WEST RIDING OF YORKSHIRE.

MR. PRESIDENT AND GENTLEMEN,—Since 1889, when von Mering and Minkowski first clearly demonstrated the relationship of the pancreas to diabetes, many important additions have been made to our knowledge concerning the functions of the gland. While, on the one hand, the experiments of Pawlow, Bayliss and Starling, and others have shown how much more complicated than had formerly been supposed are the influences which bring about the due performance of its part in digestion, the researches of Laguesse, Ssobolew, Schulze, Opie, and other workers have increased our information as to the means through which it controls the assimilation of carbohydrate material by the tissues. From being considered as merely an accessory to the digestive tract the pancreas has now come to be regarded as an organ having a most important influence on the metabolism of the body and there has accumulated a considerable mass of evidence tending to show that the part which it plays in completing the process of digestion is probably the least important of its functions. When from any cause the flow of the pancreatic juice into the duodenum is interfered with no serious disturbance of digestion necessarily follows, since its work may be performed by other agencies, but it is otherwise with the internal secretion of the gland, for, so far as we know at present, there is no other organ capable of playing the part which the pancreas does in controlling carbohydrate metabolism. One would expect, therefore, that disease of the pancreas would be accompanied by evidence of a disturbed relationship in the internal chemistry of the body, and although experiment has shown that almost complete ablation of the gland is necessary in animals before the symptoms of diabetes supervene, it is probable that in all cases where inflammation or some other pathological state interferes with its functions, a condition tending towards glycosuria is produced.

While our knowledge of the physiology and pathology of the pancreas has thus rapidly increased little or no corresponding advance has been made in the clinical diagnosis of the affections to which it is liable. Inflammatory changes, malignant disease, even cysts and calculi, offer no pathognomonic signs by which they can with certainty be recognised, and Opie in his recent monograph writes: "Disease of the pancreas is rarely recognised during life." A correct opinion may be formed no doubt in a few instances, generally by a process of exclusion, but in the majority of cases the true state of things is only learned on the operating table or in the post-mortem room. That this should be so is neither creditable to the art of medicine nor just to our patients. Disease of the pancreas is now known to be by no means rare and there is no doubt that in the past many a life has been sacrificed which could have been saved had but the nature of the disease been recognised in time and suitable treatment adopted. The difficulty in diagnosis arises chiefly from the obscurity and indefiniteness of the symptoms. Masked as they frequently are by the more salient evidences of perverted function in neighbouring organs and leading to wrong conclusions by their similarity to those of better known affections it is not surprising that disease of the pancreas is perhaps more frequently overlooked than any other serious abdominal trouble.

Not only is there a difficulty in recognising pancreatic affections during life but, as Mr. A. W. Mayo Robson was the first to point out in his lecture at the London Polyclinic in July, 1900, the symptoms of cancer of the pancreas are often so closely simulated by those of chronic pancreatitis, and the condition of the gland found at operation is so much alike in the two conditions, that it is only the after-history of the case and its response to suitable treatment that allow of their accurate differentiation. That this is a matter of the utmost importance is apparent when it is remembered that whereas operation in cancer of the pancreas is inadvisable, and whenever possible to be avoided, most satisfactory results usually follow appropriate treatment in cases of chronic inflammation. The difficulty is, however, to decide which are the cases that will benefit by operation and which are those where interference will only hasten an inevitably fatal conclusion. Hitherto there have been no satisfactory means by which this question could be decisively answered and it was mainly in the hope of finding a solution of the difficulty that some three years ago I commenced, in conjunction with Mr. Mayo Robson, an investigation of the chemical changes in the body produced by pancreatic diseases. These researches are not as yet by any means complete, for as the investigation has progressed many new and interesting issues have been raised, but, as I hereafter hope to show, the original object with which the experiments were commenced has, we believe, been gained and, not only so, but we have reason to think that the whole question of the diagnosis of diseases of the pancreas has been placed on a much more satisfactory footing than heretofore.

---

[1] The purely chemical aspect of this subject will be dealt with on another occasion.—P. J. C.

In this lecture I shall as far as possible confine my remarks to a consideration of the practical application of our observations to clinical medicine and more especially to their bearing on the diagnosis of diseases of the pancreas and the differentiation of the various affections to which this organ is liable. It will, however, be necessary for me in the first place briefly to indicate the lines on which the research was commenced and to state the theoretical considerations that formed the original basis of the work.

On carefully considering the symptoms that may be associated with the various forms of inflammation of the pancreas one is struck by the fact that a number of the more typical of them are obviously dependent on alterations in the chemistry of the body. Among such may be mentioned the tendency to hæmorrhage, apart from the presence of jaundice, the occurrence of fat necrosis, the discovery of undigested fat and muscle fibre in the stools, the appearance of sugar in the urine, and the marked wasting seen in many cases. The association of these symptoms in acute cases and the frequent occurrence of several of them in the subacute and chronic inflammations suggest that the chemical changes that give rise to them are directly or indirectly dependent on perversion of the pancreatic functions. The most characteristic and striking of the signs I have mentioned is undoubtedly fat necrosis, and whatever view of its ultimate causation is held there can be no doubt that it is almost invariably associated with obvious disease of the pancreas. Although it is most typically met with in acute and gangrenous pancreatitis, it is not improbable that similar but less evident changes accompany all forms of pancreatic inflammation, and it is to these changes that the hæmorrhagic tendency which is so characteristic of the affections is due. It is now admitted by most authorities that the masses of free fatty acids or the combination of them with lime, which constitute the lesion, are directly derived from the fat of the affected part by the fermentative action of the pancreatic secretion and that the other constituent of the fat molecule—namely, the glycerine—is absorbed into the circulation. Bearing in mind the effects produced in animals by the subcutaneous injection of glycerine it occurred to us that in man the continued action of minute doses, such as fat necrosis would give rise to, might produce such a blood state as is met with in pancreatitis, especially when to the action of the glycerine on the blood there are added the effects of the removal of calcium salts from the circulation.

Starting on the theory that there was some such connexion between fat necrosis and the hæmorrhagic tendency we commenced our investigations of the chemical pathology of pancreatitis by examining the blood of several cases for glycerine and glycerine derivatives. But, as we quickly realised that such direct proof was impossible, owing to the small amounts of blood available at the bedside and to the relatively minute quantity of glycerine likely to be present in it, we turned our attention to the urine in the hope of there finding indirect evidence in support of our hypothesis. The well-known selective power of the kidneys by which they detect and excrete abnormal constituents of the blood favoured the view that the soluble products of fat necrosis, or their derivatives, might cause changes in the composition of the urine which, owing to the large bulk of material easily available for examination, could be satisfactorily detected. Further, although glycerine when introduced into the circulation is stated to be oxidised and to increase the secretion of carbon dioxide, Catillon has demonstrated it in considerable quantity in the urine after administration by the mouth and from 50 to 60 per cent. of the quantity given has been shown to be excreted thus in dogs. Even a larger percentage than this might reasonably be expected to escape destruction in patients suffering from pancreatic affections, for in them the metabolic processes are abnormal and there is apparently a tendency to defective oxidation.

Lewin has suggested a method for detecting glycerine in the urine which depends upon the fact that oxalic acid breaks up in the presence of glycerine into formic and carbonic acids. On distilling a sample of urine from a case of pancreatitis in the way he describes, indications of the presence of a formate in the distillate were obtained which, although not very marked, were still sufficiently pronounced to encourage further investigation. Several other methods for detecting the presence of glycerine were afterwards employed, and among them was that which depends on the formation of glycerose when a solution of glycerine is heated with nitric acid. In carrying out this test we employed phenylhydrazin as the means for detecting the glycerose, and were struck by the exceedingly well-marked deposit of crystals given by pancreatic urines. Control experiments carried out with normal urines and with specimens from cases of catarrhal and obstructive jaundice, intestinal obstructions, gastric ulcer, &c., were found to be uniformly negative, so that we hoped that we had not only obtained evidence in support of our theory but also had succeeded in finding a method of distinguishing pancreatitis from at least some of the clinical conditions with which it is liable to be confused. A more extended experience showed, however, that the matter was not quite as simple as it at first sight had appeared, for although all pancreatic urines gave a reaction, a similar result was obtained in a certain number of other diseases in which there was no reason to believe that the pancreas was diseased but which were characterised by rapid tissue change and defective oxidation. It had also to be borne in mind that the reducing power of most urines is increased by boiling with mineral acids, and although it was found that either hydrochloric or sulphuric acid could be substituted for the nitric acid originally employed, a series of careful experiments carried out for the purpose failed to demonstrate that the reaction obtained in pancreatic urines was due to the so-called animal gum from which the reducing substance of normal urine is said to arise. As the success of the test appeared to depend on the presence of some abnormal constituent in the urine, the examination of a large number of specimens from cases of known or suspected pancreatic disease was next undertaken and it was found that when taken in conjunction with the clinical symptoms the reaction was of considerable assistance in diagnosis. The strength of the acid employed, the kind of acid used, the time of boiling, and other details of the experiment appeared, however, to exert considerable influence on the result, and [illegible] erous experiments a method of [illegible] which proved to be generally s [illegible] y describe and call, for convenience of reference, reaction "A."

The specimen of urine to be examined is filtered, and ten cubic centimetres of the filtrate are poured into a small flask. One cubic centimetre of strong hydrochloric acid is added and a funnel having been placed in the neck to act as a condenser the flask is placed on a sand bath and gently boiled for ten minutes after the first sign of ebullition is detected. A mixture of five cubic centimetres of the filtered urine and five cubic centimetres of distilled water is then poured into the [illegible] The excess flask, [illegible] ur grammes of ac [illegible] minutes to of lea [illegible] is filtered allow of the [illegible] through a moistened filter paper and the flask is washed out with five cubic centimetres of distilled water on to the filter. To the clear filtrate are now added two grammes of powdered sodium acetate and 0 75 gramme of phenylhydrazin hydrochlorate and the mixture is boiled for from three to four minutes on the sand bath. The hot fluid is then poured into a test tube and allowed to cool undisturbed. After the lapse of a period, varying with the severity of the case from on to 24 hours, a more or less abundant flocculent yellow deposit is found at the bottom of the tube, and this when examined under the microscope with a $\frac{1}{6}$-inch objective is seen to consist of sheaves and rosettes of golden yellow crystals. As the presence of sugar in the urine would obviously vitiate the results thus obtained it is necessary before proceeding to the test to make sure that the untreated urine does not give a reaction with phenylhydrazin. This may roughly be done with Fehling's solution, or some similar test, but it is better to carry out a control experiment with phenylhydrazin hydrochlorate and sodium acetate in the manner I have just described, omitting the preliminary boiling with hydrochloric acid. Should the control experiment reveal even a trace of sugar it must be removed by fermentation, with subsequent boiling to expel the alcohol formed, before the investigation is proceeded with. The presence of albumin in the urine is also liable to cause trouble, and it is best got rid of either by treatment with ammonium sulphate or by acidifying with acetic acid, heating, and filtering.

The results obtained by this method were found not to be absolutely trustworthy, although a useful aid in diagnosis, since a positive reaction was also obtained in patients suffering from certain other diseases where active tissue change was taking place, such as cancer, adenitis, pneumonia, &c. For a long time the positive reaction given by these non-pancreatic cases diminished the practical usefulness of the test but eventually a means by which the cases of pancreatitis might be distinguished was devised, and we now believe that by combining the results of the two it is possible in the large majority of cases to make a trustworthy diagnosis from the examination of the urine alone. The differentiating test depends upon the fact that the formation of the crystals described in reaction "A" is interfered with in inflammation of the pancreas by a preliminary treatment of the urine with perchloride of mercury, while such treatment does not affect the appearance of the crystals in cases of cancer of the pancreas and the other conditions which give rise to a positive reaction. The procedure, which I shall refer to as the "B" reaction, is as follows.

20 cubic centimetres of the filtered urine are thoroughly mixed with half its bulk of a saturated solution of perchloride of mercury. After standing for a few minutes it is carefully filtered and to ten cubic centimetres of the filtrate one cubic centimetre of strong hydrochloric acid is added. The mixture is then boiled for ten minutes on a sand bath and subsequently diluted with five cubic centimetres of the filtrate from the mixed urine and perchloride of mercury solution and ten cubic centimetres of distilled water. After cooling it is neutralised with four grammes of lead carbonate and the succeeding stages of the operation are carried out as in reaction "A"

Experiments were next set on foot with a view to still further differentiating the various forms of disease to which the pancreas is liable, especially chronic inflammation and malignant disease, for, as I have already mentioned, the accurate diagnosis of these two conditions is a matter of the utmost importance to the patient. Careful observation of the crystals isolated from the urines of various types of pancreatic disease showed that while there was a general resemblance variations in form occurred. On classifying the crystals from a considerable number of cases it was found that those obtained in malignant disease were as a rule coarser and broader than those seen in simple inflammation and that in the simple inflammations again the crystals from acute cases were on the whole somewhat finer than those seen in most instances of chronic inflammation. The lines dividing these types were not hard and fast, however, and although to the experienced eye a suggestive difference was discernible, great reliance could not be placed on a differential diagnosis based on the microscopical characters of the crystals alone In the course of our further investigations a character of much greater value was discovered, and this was the differing rate of solubility of the crystals in dilute sulphuric acid. It was at first thought that this difference depended on the varying size of the crystals, but more extended experience proved that this was not the case; for although the coarser crystals took, as a rule, longer to dissolve completely than the finer ones, exceptions were met with and the time of solution appeared to be directly dependent on the intensity of the inflammatory changes in the gland. If the crystals obtained in reaction "A" be observed under the microscope whilst a 1 in 3 dilution of strong sulphuric acid is being irrigated under the cover-glass, they will be seen to turn brown when the acid reaches them and then to dissolve. In acute pancreatitis the interval that elapses between the first appearance of the brown colour and the complete solution of the crystals under observation varies from a few seconds to half or three-quarters of a minute; in chronic pancreatitis it extends from half to one and a half or rarely to two minutes, while the crystals of malignant disease as a rule do not completely disappear for from three to five minutes. To form a trustworthy opinion it is advisable to take the mean of several observations, so that slight variations unavoidably present in the conditions of the experiment may be neutralised and comparable results obtained. The crystals met with in non-pancreatic cases turn brown and dissolve in dilute sulphuric acid in a similar way to those obtained in pancreatic affections, and they most closely resemble those of chronic pancreatitis in their time of solution which generally ranges round one minute. Phenylglucosazone crystals, with the strength of acid mentioned, only slowly assume the brown colouration and take five minutes or more to dissolve.

The time limits mentioned are the result of the comparison of a large number of observations and will as a rule be found to be correct. The exceptions, which are in most instances cases of malignant disease of the pancreas, I shall consider in detail when dealing with the examinations which I have made of specimens from cancer cases. The practical results of the examination of the urine by the methods which I have described may be briefly summarised as follows: 1 If no crystals are found by either the "A" or the "B" method the pancreas is not at fault and some other explanation of the symptoms must be sought. 2. If crystals are obtained by the "A" method but not by the "B" reaction active inflammation of the pancreas is present and surgical interference is generally indicated. (*a*) The crystals obtained by the "A" method will in acute inflammation dissolve in 33 per cent. sulphuric acid in about half a minute. (*b*) In chronic inflammation the crystals obtained by the "A" method will take one or two minutes to disappear. 3. If crystals are found in preparations made by both the "A" and the "B" methods there may be—(*a*) malignant disease of the pancreas, when the crystals will as a rule take from three to five minutes to dissolve and operation is inadvisable; (*b*) a damaged pancreas due to past pancreatitis, when the crystals will dissolve in from one to two minutes; (*c*) some disease not connected with the pancreas, when the crystals dissolve in about one minute. In the two latter, (*b*) and (*c*), the urgency of the symptoms and the condition of the patient must decide the need for an exploratory incision, but there is generally not much difficulty in referring the case to one or other of the groups when the clinical history is considered in conjunction with the result of the examination of the urine.

Other aspects of the examination of the urine in diseases of the pancreas may now be mentioned. The most important of these from a diagnostic point of view is the microscopical investigation of the centrifugalised deposit. This in nearly 30 per cent. of the specimens from cases of pancreatic inflammation that I have examined has shown calcium oxalate crystals and if those urines in which bile was present be excluded the proportion is more than doubled. The significance of oxalate of lime crystals has long been debated, but the marked tendency to increased oxalate excretion in diabetes and its frequent rise simultaneously with a decrease in the output of sugar have suggested that it is associated with the incomplete oxidation of carbohydrates. The remarkably frequent occurrence of these crystals in pancreatitis lends support to this view, for it is only in the comparatively early stages of the lesion that they are found; and when, as sometimes occurs, the disease progresses and glycosuria occurs the formation of calcium oxalate appears to cease. Further, their presence seems to indicate that a stage antecedent to diabetes and closely related to it is reached in most cases of pancreatic inflammation, whether they ultimately develop into the typical condition or not. Dextrose has only been met with in a very few of the urines examined and in all instances where it has been detected the case has been either one of acute inflammation or advanced cirrhosis of the pancreas. The ordinary forms of infective subacute and chronic inflammation do not appear to give rise to dextrosuria in the stages where they come under the observation of the surgeon. As Kulz and Vogel have detected a pentose in the urine in diabetes and Hammarsten has demonstrated a similar substance in a nucleo-proteid obtained from the pancreas, the possibility of pentoses being present in the urine in pancreatitis had to be borne in mind, but I have been unable experimentally to verify the fact. Acetone and di-acetic acid were also sought for in a considerable number of cases, but no evidence of their presence could be found except in a few instances of advanced pancreatitis with typical diabetes.

In view of the fact that inflammation of the pancreas is in a considerable number of cases associated with more or less jaundice it is not surprising to find that bile pigments were *discovered in 60 per cent. of the urines examined. In some* only a faint trace was detected with difficulty, while in others there was a very large quantity. All the specimens but one, derived from cases of malignant disease of the pancreas, showed a considerable amount of bile in the urine. No special significance can be attached to the quantity present, as in many cases with chronic catarrh the urine is as deeply coloured as it is in most cases of malignant disease. *The removal of any obstruction of the common duct that* may exist is generally followed very shortly by the disappearance of bile from the urine, but in a few cases where the condition is of long standing bile pigments may be found, although in much diminished quantity, several weeks or even months after the operation.

In the course of our observations over 300 specimens of urine have been investigated, but of those about 100 were *only employed as controls. The remainder may be divided* into an earlier series on which the preliminary investigations were carried out, and a succeeding series of 170 specimens derived from 111 cases of suspected pancreatic disease where the diagnostic value of the methods described was put to the test. As I have already sketched the lines along which the investigation proceeded it will not be necessary to refer further to the first series, except to state that all the cases *were under Mr. Mayo Robson's care and had been found at* operation to be suffering from some disease of the pancreas.

In the second series specimens of urine were sent to the laboratory for examination without any indication as to the nature of the report expected and in many of the earlier ones the condition of the pancreas was ascertained while the examination was being made. By thus separating the clinical and experimental

bias on the part of the

avoided and a true estimate

formed. Among the earliest cases dealt with in this way I may mention two which were examined on the same day. Both were deeply jaundiced and presented very similar clinical symptoms, but on the operating table one was found to have well-marked pancreatitis with a stone in the ampulla of Vater, while in the other no enlargement or hardening of *the pancreas could be detected although some gall-stones* were found in the gall-bladder. The results of the examination of the urines entirely agreed with the conditions found, for while with the sample from the first case a well-marked reaction was obtained, no crystals of any sort could be isolated from the urine of the second. Similar encouraging confirmations of the value of the tests were met with in many other cases, but it will facilitate matters if I *consider the whole series in groups arranged according to the* lesion present, only referring to individual cases where they illustrate some special point or contain elements of particular interest.

GROUP 1.—ACUTE PANCREATITIS.

The urine from three cases of acute pancreatitis has been investigated. All were under Mr. Mayo Robson's care and two of them were operated on by him. In the third death occurred shortly after the patient was first seen and as unfortunately no post-mortem examination was permitted the diagnosis is not absolutely certain but clinically the case was a typical one of acute pancreatitis. In the two cases operated on one was found to have pancreatitis with fat necrosis, while in the other a slough of the pancreas was removed and a stone was found in the common duct. A typical reaction was obtained in all three when the urine was examined, the crystals obtained by the "A" method dissolving in a quarter to three-quarters of a minute. An interesting fact was observed in connexion with one of the cases (that showing fat necrosis)—namely, that a month after operation, when the patient was convalescent, the crystals which were obtained from the urine, but now in much reduced numbers, took from one minute to one and a half minutes to dissolve instead of the three-quarters of a *minute noted before and shortly after the operation.*

GROUP 2.—CHRONIC PANCREATITIS.

Chronic pancreatitis is an inflammatory process due in the greater number of cases to an infection travelling up the pancreatic ducts. The infection may originate in a catarrh of the duodenum or may result from stagnation of the bile and pancreatic secretion as a consequence of partial or complete blocking of their common channel of entry into the intestine. When an obstruction occurs it is in most instances due to a gall-stone lodging in the pancreatic portion of the common duct or in the ampulla of Vater. In 30 of the 51 *cases in this group a biliary calculus was found in one or* other of these situations. The urine in all cases yielded typical crystals dissolving in dilute sulphuric acid in about one minute, although in three instances they completely disappeared in half a minute and in four others one and a half minutes elapsed before solution was complete. Crystals dissolving in three-quarters of a minute were obtained in two cases where pancreatic calculi were the cause of the obstruction. *An account of the first case was published by Mr.* B. G. A. Moynihan in THE LANCET of August 9th, 1902, p. 355, while the other has been described in detail by Mr. Mayo Robson in his recent Hunterian lectures. Obstruction from causes other than calculi are occasionally met with, and in one, where a malignant growth of the ampulla of Vater blocked the entrance of the common duct into the duodenum, crowds of fine crystals dissolving *in from half to three-quarters of a minute were obtained* from the urine; in another, where a fold over the mouth of the papilla and a much dilated common duct were discovered at operation, the urine yielded crystals dissolving in from one minute to one and a half minutes. Sometimes the inflammation of the pancreas goes on to suppuration and either a localised abscess is formed or the duct is found to be filled with pus. Two examples of each of these *conditions have been met with and all gave a typical* pancreatic reaction. The most recent was a striking illustration of the difficulties attending an accurate diagnosis in pancreatic affections and also shows how a chemical examination of the urine may throw light on a difficult case. The patient, a man, aged 65 years, was deeply jaundiced and much emaciated, a swelling could be felt in the region of the pancreas, and the general condition suggested *malignant disease although a varying temperature* indicated septic absorption. A sample of the urine sent to me for examination by Dr. Hector W. G. Mackenzie yielded by the "A" method many crystals soluble in one minute, while with the "B" reaction only amorphous granules were obtained. I accordingly diagnosed inflammation of the pancreas and the sequel proved the correctness of the diagnosis, for when the abdomen was opened a stone was *found in the ampulla of Vater and on removing this pus* oozed out of the duct of Wirsung. Mr. Mayo Robson, who performed the operation, also found that the pancreas was very much enlarged. Further cases in this group might be mentioned where the chemical diagnosis proved of considerable assistance but I will only refer to one. This was that of a man who had for some time been steadily losing flesh and in the three months before *he was seen in consultation by Mr. Mayo Robson was said* to have lost over two stones in weight. For two months he had been deeply jaundiced and physical examination showed enlargement of the liver and spleen and some swelling over the pancreas. The gall-bladder was also dilated and altogether the case was strongly suggestive of cancer of the pancreas. His urine, however, gave crystals dissolving in one minute by the "A" method, while the "B" reaction was negative. At the operation which was subsequently performed chronic pancreatitis with a stone in the common duct was found and the diagnosis based on the urinary examination thus proved to be correct.

In 17 other cases where the reaction was obtained the pancreas was more or less enlarged but no obvious obstruction of the ducts was discovered at the time of operation. In six of them bile pigments were found in the urine, so that the inflammatory process would appear to have travelled up the bile and pancreatic ducts either as a direct extension of a catarrh of the duodenum or as the result of an obstruction of the common duct which had passed away.

GROUP 3.—MALIGNANT DISEASE OF THE PANCREAS.

The diagnosis of malignant disease of the pancreas from the examination of the urine depends chiefly on the appearance of the crystals and the time of solution of those *obtained by the "A" reaction in dilute sulphuric acid, for* like non-pancreatic cases they give a reaction by both the "A" and the "B" methods. Out of the 15 cases of cancer examined a correct diagnosis was made in 13. In one, although the coarseness of the crystals raised a suspicion of malignant disease, only a doubtful opinion was given as complete solution was effected in one or two minutes. In the other case a diagnosis of chronic inflammation of the pancreas was incorrectly made since the urine yielded fairly fine crystals dissolving in from one minute to one and a half minutes by the "A" reaction and the "B" reaction gave only a few crystals. In four of the instances where the opinion given was confirmed typical coarse crystals dissolving in from four to five minutes were obtained, while in the other 11 from three to four minutes elapsed from the first brown colouration of the crystals to their complete disappearance. In the majority, therefore, of these cases the examination of the urine was of considerable assistance in solving a difficult problem, but in a small proportion the result was not so satisfactory. The explanation of the difference in time of solution met with in various cases of malignant disease was not at first apparent, but the results of the examination of two specimens from a case of cancer of the pancreas in March of last year suggested that it was probably associated with the amount of inflammatory reaction set up and the situation and extent of the growth. The first specimen referred to, examined on March 27th, showed coarse crystals soluble in from three to four minutes, while the second, taken a week later, yielded crowds of fine crystals dissolving in under half a minute—that is to say, the latter approximated in appearance and solubility to those met with in acute pancreatitis, whereas the former were typical of malignant disease. In a communication accompanying the second sample it was stated that the condition of the patient had markedly changed since the last examination, and as he very shortly afterwards succumbed it appeared probable that the alterations noticed in the urine and in the clinical condition were associated with a rapid extension of the growth. Two cases under the care of Dr. J. Stewart of Leeds lend support to this view. In one, where coarse crystals dissolving in about four minutes were obtained, the disease affected the body of the gland but did not encroach on the duct; in the other the growth was confined to the head of the pancreas and the presence of fairly fine crystals dissolving in from one minute to one and a half minutes led, as I have already mentioned, to an incorrect diagnosis of chronic pancreatitis. Clinically also this last case was of interest as I hear from Dr. Stewart that careful palpation failed to reveal the distension of the gall bladder that usually accompanies malignant disease of the head of the pancreas. The explanation was found at the post-mortem examination when no trace of a gall-bladder could be discovered.

The correct diagnosis of malignant disease from an examination of the urine requires considerable care, for although the typical, broad, slowly dissolving crystals are met with in most instances, in a few cases the presence of an attendant pancreatic inflammation is liable to obscure the issue and to lead to an incorrect opinion. The mistake of diagnosing inflammation for cancer can be avoided by carefully noting the result of the "B" reaction and the difficulty now is to differentiate it as a rule from some non-pancreatic affection. In all cases of suspected malignant disease of the pancreas it is advisable to investigate the fæces as well as the urine, for the presence of undigested muscle fibre, the absence of bile pigments, and a large amount of fat in the stools are strongly in favour of cancer.

GROUP 4.—CYST OF THE PANCREAS.

The urines from two cases of cyst of the pancreas have been examined and both gave results similar to those met with in chronic pancreatitis. The crystals obtained by the "A" method were fairly fine and dissolved in about one minute.

GROUP 5.—CASES WITH GLYCOSURIA.

Considering the effect produced in the lower animals by removal of the pancreas the relative infrequency of glycosuria as a symptom of pancreatitis is somewhat remarkable. In chronic pancreatitis sugar is rarely met with, while even in acute destructive lesions glycosuria is rather the exception than the rule. In the 90 cases of proved pancreatic disease investigated sugar has only been found in the urine of five and these were all examples of advanced chronic inflammation. In neither the urines of the 15 cases of malignant disease nor in the samples from the three acute cases was any reducing substance met with. The relation of the fibrous tissue of chronic pancreatitis to the islands of Langerhans is, according to Opie, the determining factor, and whereas in the interlobular variety diabetes only supervenes when the sclerotic process has advanced to a late stage and the interacinar islands are destroyed along with the secreting tissue, in the interacinar form diabetes is an early symptom as the islands of Langerhans are more or less involved from the commencement. Since obstruction of the pancreatic duct gives rise to interlobular pancreatitis and obstruction is the most common cause of inflammation, glycosuria is relatively uncommon in chronic pancreatitis.

The methods adopted for the examination of the urine when sugar is present have already been described and, although our experience of them is not as yet large, the results obtained lead us to hope that they will prove of assistance in differentiating pancreatic from non-pancreatic diabetes. In one of the five cases mentioned the pancreatic origin of the disease was proved post mortem and histological examination of the gland showed that the fibrous tissue of which it was mainly composed had destroyed practically the whole of the glandular structure. Only a few isolated patches of pancreatic tissue could be seen and in these no trace of the islands of Langerhans was detected. The specimen of urine that I examined was taken in the post-mortem room by Dr. C. Powell White from the bladder of the patient who was killed in an accident near St. Thomas's Hospital. It contained a large amount of dextrose and after this had been removed showed by the "A" method many fine crystals soluble in half a minute. The "B" reaction gave only an amorphous deposit of granules. Similar results were obtained with a sample of urine kindly secured for me by Mr. J. Tait from a case of acute pancreatitis described by Mr. W. Gifford Nash in THE LANCET of Nov. 1st, 1902, p. 1192. My examination was made over a year after the first onset of the symptoms but the urine still contained a considerable amount of sugar, and crystals dissolving in from a quarter to half a minute were prepared by the "A" method. A second specimen, kindly sent to me by Mr. Nash in February of this year, showed dextrose but no acetone or di-acetic acid. A well-marked pancreatic action was given by the "A" method, the crystals dissolving in from half to three-quarters of a minute, but no precipitate of any sort was found in a preparation made by the "B" method. These results indicate, I think, that although the operation had been successful in relieving the acute condition a subacute or chronic pancreatitis still remained.

That an inflammation of the pancreas may occasionally progress in spite of the removal of the initial obstruction of the duct which gave rise to it is also shown by two cases operated on by Mr. Mayo Robson some years ago and samples of whose urine I have recently had the opportunity of examining. In one the condition of the pancreas found at the time of the operation was such that malignant disease was diagnosed and a bad prognosis was given. The patient is still alive and apparently well, however, eight and a half years after the operation. Her urine which I examined in February showed an abundance of dextrose but no acetone or di-acetic acid. Crystals dissolving in three-quarters of a minute were obtained by the "A" method but none could be isolated by the "B" method. The second case was operated on in 1898 and a sample of the urine examined recently gave similar results to those just mentioned. In this case, too, a swelling of the head of the pancreas, thought at the time to be malignant, was found at the operation, but the rapid increase of weight and subsequent good health of the patient showed that the tumour was really inflammatory. The remaining case of the five in this group was that of a man who had suffered for some years from what appeared to have been gall-stone colic. His urine contained sugar and yielded crystals by the "A" method which dissolved in half a minute.

GROUP 6.—CASES WITH SYMPTOMS RESEMBLING THOSE OF PANCREATITIS.

In 35 cases the clinical symptoms suggested for a time the presence of an inflammation of the pancreas but their subsequent course and the conditions found on operation confirmed the diagnosis based on the examination of the urine that the pancreas was not affected. Seven of them turned out to be cases of obstructive or catarrhal jaundice. One of the former was particularly instructive as it had been diagnosed by a well-known London physician as being a case of cancer of the pancreas and was regarded by him as hopeless. The result of the examination of a specimen of urine sent to me for an opinion did not agree with this view, however, as I failed to obtain any crystals by either the "A" or the "B" methods. I consequently ventured to suggest that the pancreas was not diseased at all. Mr. Mayo Robson shortly afterwards operated on the patient and found that the pancreas was perfectly normal but that there was a large biliary calculus lodged in the bile duct above the duodenum and it was *from this that the jaundice and other symptoms arose* A perfect recovery followed and the patient is now quite well. Several cases of ulceration of the stomach and duodenum have been differentiated from pancreatic diseases by the absence of the characteristic reaction in the urine. In malignant disease of the stomach the positive results obtained by both the "A" and the "B" method have served to exclude pancreatitis, while the solubility of the crystals in about one minute showed that the symptoms were probably not due to cancer of the pancreas. I have only *had the opportunity of examining* the urine *from one case* of intestinal obstruction, but as this did not give the pancreatic reaction it is most likely that acute pancreatitis may be diagnosed from it by this means in spite of the similarity of their clinical phenomena. In most cases of malignant disease of the intestine crystals dissolving in one minute or thereabouts have been obtained from the urine, but in one case of cancer of the rectum none could be found.

GROUP 7.—RE-EXAMINATION OF OLD CASES.

When a patient with pancreatitis is operated on the symptoms are relieved and he is generally restored to apparent health, but the cases of glycosuria I have quoted as occurring some years subsequently to surgical treatment show that in some at least there is a permanent disturbance of metabolism which may ultimately develop into diabetes. Such a progressive lesion is not common, but the examination of the urine in a considerable number of cases during convalescence and at varying intervals afterwards has indicated that in most there is a permanent alteration in the chemical equilibrium of the body. While for all practical purposes the work of the pancreas may be efficiently carried out, the damage it has sustained would appear to interfere with an absolutely normal performance of its functions and it is probable that the oxidation of carbohydrate material is imperfect in all cases of healed pancreatitis. So long as there is any active inflammation of the gland the "B" reaction is negative, but when the active stage is passed both the "A" and the "B" methods are found to yield crystals. In many cases where the urine has been examined at intervals for several months after operation an abundant crop, dissolving in about one minute, has been obtained, and in two cases where the urine was re-examined two and a half years after recovery a well-marked reaction was given by both methods. I have recently had sent to me samples from several cases on which Mr. Mayo Robson operated for pancreatitis as long as six years ago, and these all gave similar results. In about half the recovered cases also calcium oxalate crystals have been found in the urine and in several cases of pancreatitis with jaundice it has been noticed that they have made their appearance when the icterus was relieved by *drainage of the* biliary passages.

I have not attempted to deal with the cases examined individually, as most of them have been under Mr. Mayo Robson's care and are either described in the last edition of his book on Diseases of the Gall-bladder or have been dealt with by him in his Hunterian lectures. In THE LANCET of Sept. 27th, 1902, p. 856, Mr. Moynihan has recorded several instances of chronic inflammation of the pancreas, samples of the urine from which I had examined and I take this opportunity of thanking him and a number of other surgeons and practitioners in various parts of the country who have interested themselves in these investigations and have materially assisted the work by supplying specimens from cases under their charge.

It is unfortunate, from the point of view of our researches, that it has not been possible to obtain much evidence as to the histological condition of the pancreas that accompanies the changes in the urine described. Of the three cases where a post mortem examination was allowed one was a spheroidal-celled carcinoma and has already been referred to; the other two were examples of an early and advanced stage of chronic pancreatitis respectively. Microscopical examination of the gland from the former case showed engorgement of the blood-vessels, cloudy swelling of the parenchyma, and in places some excess of fibrous tissue, while in the latter an advanced condition of fibrosis was found.

In spite of the paucity of post-mortem evidence in support of the diagnostic value *of the methods of urinary examination* mentioned there is no doubt that they are clinically useful. We do not claim that they are pathognomonic or that, taken alone, they will enable a correct opinion to be formed in every case, but we do think that when the results of the examination of the urine are considered in conjunction with the clinical symptoms a trustworthy diagnosis is in nearly all cases of pancreatic disease capable of being arrived at. A much more extended experience, dealing with a considerably larger number of cases than it has been possible for us to obtain, will be necessary before their exact value can be finally determined, but so far as our observations go they lead us to think that in future an exploratory operation will not be necessary to determine the presence of a pancreatic lesion and that chronic pancreatitis will no longer be found in the post-mortem room as the cause *of death* in supposed inoperable cases of "cancer" of the pancreas. The tests are not yet perfect and our excuse for bringing them forward at this stage is a desire to place in the hands of the profession an aid to diagnosis which, however incomplete, has proved in our hands of great assistance in many difficult cases. We can only hope that the experience of others will be equally happy and that *an early recognition of disease of* the pancreas by an examination of the urine may in some cases prevent suffering and lead to the saving of lives that might otherwise have been sacrificed.

And now, Sir, it only remains for me to thank you and the Council of this College for the honour you have done me in permitting me to deliver this lecture It is an honour that I deeply appreciate and I can only trust that I have proved worthy of your confidence and of my predecessors in the lectureship.

ACUTE APPENDICITIS: ITS DIAGNOSIS AND THE INDICATIONS FOR OPERATION.[1]

BY WILLIAM RUSSELL, M.D., F.R.C.P. EDIN.,
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH;
LECTURER ON [illegible] WOMEN,
EDINBUR [illegible] THE
UNIV [illegible]

INTRODUCTORY.

NOTHING is more valuable and nothing can be more misleading in medicine than personal or individual experience. This seeming paradox is perhaps specially applicable to the clinical and therapeutic questions which surround the cæcum, for in this domain each individual physician, surgeon, and general practitioner tends to base his views and methods on his personal experience. One man calls in the knife the moment he scents appendicitis; another holds lingeringly to the dying faith in a stercoral *typhlitis* and perityphlitis, and each man is prone to continue to act in accordance with the results of a limited personal experience. It is now more than 20 years since the vermiform appendix [illegible] as the main factor in what aforetim [illegible] The predominance of the [illegible] has been steadily asserted and hundreds of operations have afforded opportunities for the confirming of its position and for a reasonable classification of the morbid changes which affect it. In this connexion it will not be uninteresting to you to know that in the medical statistics of the Edinburgh Royal Infirmary for 1891–92 there are four cases of appendicitis, three of typhlitis, and nine of perityphlitis. In 1894–95 the cases of appendicitis rose to 21, while perityphlitis has two, and typhlitis has disappeared from the list. In 1901–02 both terms have disappeared and appendicitis only is retained. *Many writers have formally given* the old typhlitis and perityphlitis a place in the classical mythology of medicine and assure us that no one has ever seen or ever will see a simple perforation of the cæcal wall or a perityphlitis not due primarily to the appendix. Some writers are more judicious and recognise a small percentage of such cases, some even placing them as high as 5 per cent. Were the statements of the former class to be taken as correct I could claim a unique experience, for in a comparatively small experience I have had four such cases. I have had three cases of acute perityphlitis due to primary lesion at the cæcum; one case at the operation showed marked pericæcal inflammation, while the appendix showed none, and a few days later we had, unfortunately, the opportunity of seeing fæcal ulcers in the cæcum; another fatal case was the result of perforation of one of a number of fæcal ulcers; the third occurred in an old man and proved rapidly fatal without perforation or ulcer; the fourth case, also a fatal one, was of chronic perityphlitic burrowing abscess in which the appendix was not involved and where the diagnosis before I saw the patient was malignant disease. I mention my experience to accentuate one half of the seeming paradox with which I opened—namely, that nothing may be more misleading than the personal experience of any one of us if taken by itself and not brought into relations with the experience of others. Whatever lingering sentiment may cling to the older views the evidence is overwhelming that in something between 95 and 100 per cent. of acute affections at the cæcum the primary seat of grave trouble is the appendix and that were it not for the appendix perityphlitis would be a rare occurrence.

---

[1] The opening paper read at the discussion on this subject before the Edinburgh Medico Chirurgical Society on Jan. 20th, 1904.

THE DIAGNOSIS OF ACUTE APPENDICITIS.

In approaching this question it is necessary to have a clear conception of the condition we seek to diagnose. I do not, however, propose to dwell in detail upon the varied anatomical changes which are met with in the appendix as a result of morbid action; but there are some points which materially assist us in our efforts at differential diagnosis. It is important to bear in mind in the first place that the appendix varies in length and in calibre, in its position relative to the cæcum, and in the form of its mesentery. Moreover, the meso-appendix also carries its blood-supply. In the second place two morbid conditions may arise in connexion with the appendix—namely, (1) inflammation and (2) necrosis, going on to gangrene. The intensity of the inflammation varies from a catarrh of its mucous membrane to a parietal inflammation involving all its coats or an inflammation accompanied by ulcers which may or may not perforate. Necrosis or gangrene of the entire appendix is sometimes, if not always, determined by a short mesentery which gives the appendix a sickle shape or by some other mechanism which interferes with the blood-supply. Van Cott goes so far as to hold that the primary local condition in appendicitis is a trophic one which makes it a point of least resistance for the action of virulent organisms. The fact that appendicitis is much less frequent in women than in men is probably in part due to there being a second source of blood-supply in women by way of the appendiculo-ovarian ligament. This anatomical point is of important significance, for various conditions at the cæcum or of the appendix itself may impede and even arrest the arterial blood-supply so that necrosis and gangrene readily follow. The two other anatomical points which seem to me of most importance are the calibre and perhaps the length of the appendix or the relation between these and the relation of the lumen of the appendix to the cavity of the cæcum. I do not venture to lay down definite rules but it is by recognising the existence of differences in the directions indicated that we are able to understand how the appendix in certain persons, from its shape, size, position, or curvature, is bound to give trouble to its possessor on the slightest provocation, while in others from birth to death it never indicates its existence, no matter what the gastro-intestinal experience of the individual may have been in other respects.

On this anatomical difference of position and of lumen depends and hangs the question of inflammation. Why does the appendix inflame and not the cæcum? I take from A. O. J. Kelly of Philadelphia the idea, which I apply more generally, that the question is essentially one of drainage. Secretion from the mucous membrane of the appendix or fæcal matter entering from the cæcum and not expelled form an excellent nidus for the growth of the micro-organisms of the intestine, but such conditions do more—they have been shown experimentally to be the very conditions which rapidly exalt the virulence of that otherwise harmless organism, the bacillus coli communis. Kelly, Deaver, and others have shown by a large number of observations that this organism is the most common bacterial agent, although not the only one, in the determination of acute inflammation in the appendix. It is important to realise that the exaltation of virulence of the organism mentioned takes place in other bowel conditions as obstruction, strangulation, and volvulus, but for our present purpose it is still more important to know that it also takes place in diarrhœic conditions and in constipation. The variability in the measure of this exaltation of virulence determines the great differences in the clinical manifestations and in the ultimate issue in individual cases. But this question of drainage requires further consideration and in this connexion I believe that the condition of the mucous membrane of the cæcum as a factor in causing the block is forgotten. We never forget that a duodenal catarrh causes a block of the common bile duct, but at the cæcum we are so taken up with the appendix that we ignore the possibility of the block which determines and keeps up the inflammation being caused by a like condition at its mouth. We must, I think, accept this proposition. The block, however, may be associated with a fæcal concretion in the appendix and this association is frequently present in the fulminating type of appendicitis. Here also we have to be on guard against unwarrantable conclusions. Fæcal concretions are common in the appendix without any trace of irritation but if a fæcal concretion and a catarrh operate together then we have the conditions which may lead to rapid perforation. But even then the issue turns on the virulence of the organism present. I have seen a fæcal mass on a surgeon's finger tip a second or two after he had introduced his hand into the abdominal cavity and yet the patient never showed an anxious symptom after the removal of the perforated appendix. In connexion with this question of fæcal concretion Fowler records a unique case in which gangrene of the appendix was due to a gall-stone entrapped and stuck at its orifice.

Following upon the foregoing considerations the first point which appears to me to call for consideration is the question of "appendicular colic"—is there such a condition and what view do we take of it? The sudden onset of severe abdominal pain, perhaps vomiting, muscular rigidity of the abdominal wall or of the lower right segment of it, and tenderness are known to all of us. Talamon argues that this sudden onset of pain is due to a scybalous concretion formed in the cæcum becoming suddenly engaged at the mouth of the appendix. Fowler denies the occurrence of appendicular colic; Hawkins questions it. Personally I do not see how the manifestations referred to are to be otherwise explained than by a temporary embarrassment to the appendix drainage. We all know that an attack of the kind indicated may come on in the night; that after hot applications and a dose of castor oil or of a saline laxative, the individual may be well enough to be at business that day or the following day. No medical man sees him, for the condition is looked upon as indigestion or colic due to constipation and only requiring domestic skill. We have seen cases where a second and a third recurrence of this experience formed the historical back-ground to a tragedy; we have known it repeated over a period of many years and no tragedy to follow.

This question of appendicular colic lies at the threshold of the diagnosis of appendicitis; from it you easily build up the whole clinical story of acute appendicitis. You pass from the mere mechanical and physical embarrassment of colic to the superadded inflammation, perforation, or necrosis. The symptoms of acute appendicitis are common to various abdominal illnesses—sudden onset of pain which may be of extreme severity, vomiting, tenderness, rigidity, a measure of shock with an accelerated and feeble pulse, and a varying degree of elevation of temperature—so that appendicitis has been mistaken for many things; amongst them are acute indigestion, gastric perforation, internal hernia, renal and hepatic colic, while diaphragmatic pleurisy and croupous pneumonia have been thought to be appendicitis. It would be treating the members of this society with scant respect were I to occupy their time with a reproduction of the points determining the differential diagnosis in all these. There are. however, two phenomena which I venture to deal with—namely, pain and tenderness. With regard to pain I am often impressed by the undue significance attached to the site of pain in abdominal conditions. In acute appendicitis the pain is often referred to the umbilical, epigastric, or other region, or it may be diffused all over the abdomen. When pain is thus referred to regions at a distance from the seat of lesion it frequently misleads. When such referred pains are associated with surface tenderness in the same regions they still more commonly lead to an error in diagnosis. This surface tenderness or skin hyperæsthesia is a great stumbling-block in abdominal diagnosis, and accuracy of diagnosis need never be expected until we have, by careful and patient examination, learnt to distinguish between it and the true tenderness of the diseased organ. We need not discuss the paths of referred pains, but it is well to remember that the nerves involved often carry with them to their terminal distribution a surface hyperæsthesia. One point where the surface tenderness is common has been engraved with the name of McBurney and proves a trap to the unwary clinician. Surface tenderness must not be confused with deep tenderness. At the outset of an attack the rigidity of the muscles may be a barrier to deep palpation, but with sufficient patience it is usually possible to make out the presence or absence of deep tenderness, and if we are at all successful in our manipulations pain can always be elicited by pressure on an inflamed appendix. To indicate to you that this mode of examination may be quite trustworthy, I may mention that in one case I ventured to tell the surgeon into whose hands I gave the patient that the appendix was lying behind the cæcum and the operation showed this to be correct; in other cases the point of marked tenderness is only to be found by rectal examination. I saw with one of my brethren some time ago a case in which tenderness was only elicited in this way, and it was the only guide to the origin of the lesion causing symptoms the extreme gravity of which it was easy to estimate. The situation of the tenderness in such cases is, of course, due to the position of the appendix. The importance of being able to elicit this direct tenderness of the affected part cannot be exaggerated; it is the key to abdominal diagnosis; it is recognised by all the authorities—Hawkins, Fowler, and Deaver lay stress upon it. Deaver says it is "always present." Fowler says "in the early stage of the disease tenderness is only elicited when pressure is made in the immediate neighbourhood of the appendix itself." Fowler goes so far *when considering diagnosis as to say that "every case of* colicky pains in the abdomen suddenly developed with right- [illegible] case of appendicitis [illegible] Leguen denies diffi- [illegible] cases. Nothnagel [illegible] .ve done, to a false localisation of the pain or an unusual position of the appendix. Talamon holds that the diagnosis of acute [illegible] nosis of pneumonia. One [illegible] to the state of the bowels [illegible] *is the rule it is not the* invariable condition. Some time ago I was looking after a boy with diarrhœa, elevated temperature, some tenderness in the right iliac region, and a history that suggested tuberculous ulceration of the intestine. He was seen for me by another physician but it was left to me to realise a couple of days later that we had both overlooked an appendicitis. The patient fortunately recovered after operation. In fact, the diagnosis of acute appendicitis hangs upon and depends upon our skill in eliciting the essential and distinguishing it from the non-essential and incidental.

INDICATIONS FOR OPERATION.

At the outset of this part of the subject we have to face two strong currents of opinion which cannot be called the medical and the surgical, for the surgeons are found in both camps. Indeed, the French surgeon, Leguen, divides even his surgical *confrères* into radicals and opportunists or temporisers. Probably the best designation for the two schools is to be found in our own literature and we may accept the terms "radical" and "conservative" as indicating the point of distinction between them from the operative standpoint. The radical school has attained its full effulgence in America. Since the publication of Fitz's papers in 1886 and 1888 and the establishment of the appendix as the dominant structure in the pathology of the right iliac fossa American surgeons have more and more adopted the practice of routine excision as soon as appendicitis is recognised. Fitz, Senn, Sands, McBurney, Price, Morris, and Deaver are all names associated with this school. Leguen says: "*Toute appendicite doit être operée à temps.*" If this aphorism be adopted the position is simple; differential diagnosis becomes a mere unpractical refinement and there is nothing left to discuss. The argument in support of this position is that the danger of perforation is great and that it is impossible to determine which cases will perforate and which will not. This is the main point: there are also minor although important points to which I need not refer. This is the point which appeals to those of us who have learnt to dread the possibility of an intense toxæmia from peritoneal infection and who know how rapidly this supervenes in some cases. I myself am so alive to this truly terrible aspect of acute appendicitis and the cases which I see are so often cases in which operation is clearly indicated that were I to take my personal experience of the last ten years as my sole guide I should not be far from the radical position. But here again our individual experience has to be checked by the knowledge of the results of a wider experience.

The conservative school is represented in this country by Treves, Tubby, and Hawkins; in France by Talamon; and in Germany by Nothnagel. Hawkins, on whose work Treves leans, says of the American school that "the gravity of disease of the appendix was measured by the rapidity of death in a few fatal cases rather than by the actual frequency with which a fatal event occurs." Referring to some more recent contributions to the subject he says: "They seem to be compiled by a surgeon for the use of a physician concerning a disease which is in all its aspects familar to the physician but of which the surgeon has seen only the more severe form. They assume a rate of mortality from disease of the appendix which has no foundation in actual figures." Talamon says that the position of the partisans of the extreme view would necessitate operation for every attack of intestinal colic attended with intense pain localised in the right iliac fossa, a rule he thinks sufficiently absurd in itself and not likely to be adopted. Nothnagel speaks of the operation fanatics. Treves says: "It would be as wise to advise immediate operation in all cases of ulcer of the stomach as soon as a diagnosis is made because some cases of ulcer of the stomach end in a fatal perforation." Tubby says: "I am strongly inclined to think that no judicious surgeon is prepared to tie himself down to the practice of routine early operation in all cases but would prefer to watch his cases closely and when in doubt operate at once." The warrant for the conservative position is to be found in the results of a wider experience rather than in that embraced by the individual observer. Some of these results are as follows. Furbringer in 120 cases had 10 per cent. of deaths. Renvers had from 91 to 92 per cent. of recoveries. Guttmann at the Moabit Hospital had 96 per cent. of recoveries. Curschmann in 453 cases had 4 5 per cent. of deaths and nine cases sent to the surgeons. Sahli, as the outcome of a collective inquiry, had a return of 7213 cases which showed that in 6740 cases not operated on 8 8 per cent died and 91·2 per cent. recovered. Nothnagel in 130 cases had 115 cured or improved, four deaths without operation, and 11 cases sent to the surgeons. Hawkins's statistics of the cases at St. Thomas's Hospital, if we exclude cases of perityphlitic abscess and of general peritonitis, show 190 cases with 190 recoveries and only one operated on. I have collected from the statistics of the medical side of the Edinburgh Royal Infirmary from 1891–92 to 1901–02 (that is, ten years, for one year is wanting) 268 cases, of which 189 were cured or relieved, seven were unrelieved, 23 died, and 49 were sent to the surgeons. I regret that the only point I could be sure of in the statistics of the surgical side was that all the cases of appendicitis were not operated on, showing that the conservative school is represented there also.

It thus appears that in acute appendicitis recovery takes place in from 90 to 95 per cent. of cases without operation. This is the position of appendicitis when it is judged of by a wide experience and it seems to me to be in accord with the experience of many of our brethren in general practice in the country and in the provinces who have not skilled surgical help at their call any and every hour of the day or night as practitioners have [illegible] well prove a comfort to our [illegible] but they throw a greater we[illegible] more and more imperative to watch with us, for it becomes more and more imperative to watch with the closest attention every individual case and to learn to determine the one case in the ten which if it is to be saved must be submitted to the surgeon's knife without delay.

The first question which ought to be faced in every case of acute appendicitis is: Is the appendix rapidly to perforate or promptly to become gangrenous? Early perforation and early gangrene account for most if not for all of the cases of early peritonitis with grave toxæmia. St. Thomas's Hospital statistics show 36 in a total of 264 cases and of these 27 proved fatal. Perityphlitic abscess may be regarded as a later development, but it supplies 38 cases with 28 deaths in the statistics of the same hospital. The above question ought to be formulated definitely in every acute case. The chances as shown by statistics are fully nine to one against perforation; but differential diagnosis is not based on averages, and it is equally poor comfort to be assured by many authorities that the question cannot be answered until the disaster we desire to anticipate has occurred.

As I understand the matter one great object which the promoters of this discussion had in view was to elicit whatever there is of knowledge and of experience on this point among us. I myself approach it with much diffidence but there are some points which I venture to submit. The first is that if in an acute attack I find that there have been one or two previous attacks, even mild ones, I do not hesitate to advise removal of the appendix at once. My reason for doing so is that I am satisfied that the anatomical relations of certain appendices are such that appendicular trouble is bound to arise. Recurrence is the clinical proof of this and in any recurrent attack the appendix may perforate or necrose, so that the sooner such appendices are removed the better. The second point is that if an acute appendicitis has an early rigor immediate removal is indicated. I have seen early rigor followed speedily by gangrene. But this only disposes of a small number of acute cases. When we come to the remaining cases, and if we are not to adopt routine removal in all instances, the questions necessarily arise: What are we to do? How long are we to continue the medical treatment we may have adopted? and What indications are to guide us in determining for or against operation? As regards the first of these it is quite clear that something must be done and always is done. You all know that purgatives are anathematised and that if perforation occur after the administration of such the medical man who has ordered them is looked upon as a most culpable person. I have not given purgatives in these cases for many a day, but in the earlier years of practice I used repeated doses of saline laxatives in what we called perityphlitis and I had not then a single death. All of us have seen cases where the so-called "fatal" purgative has been taken by the patient on his own initiative and his appendix has not ruptured. Such experiences have their due place. I have referred to the point as I venture to think that statements are made in this connexion which are mere presumptions and are based upon isolated and misinterpreted occurrences.

The next point that arises for consideration is the relief of pain. This is sought for by either hot or cold local applications; these are at least harmless. When, however, we go beyond local measures we at once enter a region where there is a great difference of opinion. You all know how opium and its chief alkaloid are condemned. Their administration relieves pain and gives rest to the patient and to the cæcum. The main argument against their use is that they "mask symptoms" and so they do to the inexperienced and the unwary. Nothnagel is a great advocate of opium and while I am not prepared to follow his method I have found, as he contends, that its previous administration need not mislead, and I can hardly imagine the hospital physician or surgeon being seriously misled by the mere relief of pain consequent upon its administration. If given at all it ought certainly to be limited in its use to the alleviation of intense suffering and as a temporary expedient. I even go so far as to say that the call for the continued use of opium is an indication that operation is desirable. Personally I prefer to use belladonna which relieves spasm and does not dull sensory centres. There is only one further procedure which is worth referring to and that is lavage. There exists in regard to its use some degree at least of the same feeling as exists about the giving of laxatives. The reasons given against its use are open to question. That lavage of the colon and cæcum is dangerous and may cause either perforation or gangrene is a mere arbitrary presumption and has no foundation in fact. Granting that the essential factors in the production of acute appendicitis are as I have represented, there is no measure which one would more instinctively turn to than cæcal lavage, owing to the effect it would have upon the mucous membrane at the mouth of the appendix and the effect it might have in aiding the re-establishment of appendix drainage. Professor Bourget of Lausanne has published an important monograph on this method of treatment. He uses it in all cases of acute appendicitis which come under his care, and he only advises operation after the acute symptoms have subsided and in selected cases. In his monograph he gives the details of 23 cases which occurred in his hospital practice between January, 1901, and February, 1902, which he treated on the lines indicated without a single death; and the clinical records show that some of the cases were of a grave type. My own experience of this method of treatment is too limited to say more about it than that so far as I have yet used it I am satisfied with the results.

Having thus indicated the medical measures which may legitimately be used when brought face to face with a case of acute appendicitis the serious questions still remain: How long are we to continue to use whichever measures we may have adopted? How long are we to wait for alleviation of the condition at the appendix? and What are the indications that surgical interference is the wise course to adopt? I can endorse the precept laid down by others that every individual case ought to be regarded with great seriousness and is to be closely watched for the appearance of any unfavourable symptom. There are, however, definite indications which help us to determine those questions and an accurate mental picture of the steps of morbid processes in the appendix materially aids us. Some of those indications are as follows. The continuance of severe pain in spite of local applications and the administration of belladonna internally may be taken as an indication for operation, for it mirrors almost certainly blockage and severe inflammation. The recurrence of paroxysms of pain indicates operation, for it is a proof that the appendix drainage is being recurrently interrupted and the sooner such an appendix is removed the better for the patient. Great importance is to be attached to the condition at the cæcum as revealed by careful and patient palpation; localised tenderness and swelling are the two phenomena which demand much more patient handling than they often get. If the case has been ushered in by great pain and yet appears to be a mild one as judged by cursory examination be on your guard; that is the kind of case that can perforate within 48 hours. If pain subsides and the appendix remains very tender notwithstanding the use of local applications and the internal administration of belladonna do not wait many hours for lessening of tenderness, for the appendix may be already necrosed and will shortly be gangrenous or a concretion may be completing a perforation. In these instances of necrosis and of threatening perforation the leucocyte count gives no sufficient warning of the threatening disaster. Hubbard, Dunham, Da Costa, Wassermann, and Brown have all dealt with the question of leucocytosis in appendicitis, but on this important point no strong claim of its value is made. I am very suspicious of severe onset, no great local swelling, only moderate tenderness over the cæcum, but a point where deep palpation reveals acute localised tenderness. If it is realised that a blocked and inflamed appendix accounts for such phenomena you will want proof within 24 hours that that appendix has clearly lessened in tenderness and if it has not you will want to have it removed. I again lay great stress upon the cultivation of abdominal palpation as a means of great value, not only in diagnosing appendicitis but in estimating the progress of an acute attack. In the less rapid, which is also the more common, type of case, with marked swelling and tenderness over the whole cæcum, the temperature and the pulse are an index of the measure of inflammatory reaction and the blood examination shows a leucocytosis of somewhere about 15,000 as a rule. If the local and general symptoms do not speedily subside under such measures as have been indicated, and if on further blood examination it is found that the leucocytosis reaches 20 000 or more, the case falls entirely to the surgeons, for pus has almost certainly formed and the condition has to be treated on general surgical principles.

I have sought in what I have said to formulate points which present themselves before grave peritoneal infection has taken place. When it has taken place the facies abdominalis and the rapid and small pulse are indication enough of what has happened. What the promoters of this discussion want to bring out are the indications which will enable us to anticipate this danger and by anticipation to avoid it, and to this object my remarks have been directed. When disaster has occurred there is little difficulty in recognising it and there are not two opinions as to the proper course to adopt. Beyond saying this I do not further pursue this side of acute appendicitis.

Permit me in conclusion to reiterate the main points in the line of thought which I have endeavoured to present to you to night. 1. Certain appendices are so formed anatomically that they of necessity give rise to trouble. 2. Interference with the drainage of the appendix is an important factor in determining inflammation. 3. The occurrence of appendicular colic may be taken as a warning that dangerous anatomical conditions exist in connexion with the appendix. 4. In all abdominal cases detailed palpation should be carefully and patiently carried out. 5. Too much emphasis must not be put on the site of pain or on superficial tenderness. Palpation should be directed towards ascertaining the actual condition of the diseased part. 6. Statistics show that from 90 to 95 per cent. of cases recover without operation and the chances against recurrence are as three to one or thereby. Therefore routine removal cannot be accepted as necessary. 7. Operate at once in any case with a history of previous attacks, also in all cases commencing with a rigor. 8. The chief difficulty lies in the early recognition of the cases in which the appendix will necrose or perforate rapidly. In this connexion suspect cases which show constitutional disturbance with little inflammatory reaction round the cæcum but with marked tenderness on deep palpation and an ordinary degree of leucocytosis. 9. In cases which do not call for immediate operation pain may be relieved by hot or cold local applications and by a cautious and sparing use of opium or morphine or of belladonna. Lavage may give good results. 10. Medical treatment should not be relied on for more than from 24 to 48 hours if severe pain continues or an acute tenderness on deep palpation still remains. 11. Later in the disease a continuance of the local and general symptoms along with a high leucocyte count indicates the presence of pus and the necessity for operative interference.

THE EARLY DIAGNOSIS OF ACUTE INTESTINAL OBSTRUCTION.[1]

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

IT will, I think, be found that most of us look upon the early diagnosis of intestinal obstruction in a somewhat different way from that in which it was usually regarded 40 years ago. This is because our skill in diagnosis has advanced, but in saying this I am speaking of medical men generally, for it is doubtful whether even the best of us are more skilful than the most brilliant diagnosticians of half a century ago, but as the average of skill has risen we less frequently see cases in which acute intestinal obstruction has been so long overlooked that when the patient comes to a hospital the diagnosis is obvious. Then, too, the responsibility attached to a correct diagnosis has increased enormously in this and many other diseases of the abdomen. Before surgery could help us to any appreciable extent it mattered comparatively little whether or not the diagnosis was correct, for if the patient was suffering from acute intestinal obstruction we could, unless it was due to an external hernia, do little or nothing to relieve him. But now the responsibility of the physician has increased ten-thousandfold, for if he fails to suggest that a surgeon should see a case which the necropsy shows to have been suitable for operation it is always quite likely that early surgical interference might have saved the patient's life. On the other hand, the physician may urge the surgeon to operate unnecessarily and on all grounds unnecessary operations are most undesirable.

Formerly much importance was attached to the elucidation of the problem as to whether the obstruction was high up or low down, but Fagge pointed out in his classical paper, on which most subsequent descriptions have been founded, that often the supposed points of difference in the symptoms were untrustworthy, and we now know that the symptoms are more dependent upon the cause of the obstruction than upon its situation. He classified his cases according to the cause and all the best descriptions since have followed him, as it is important for the surgeon to know the cause for which he has to search. But the result of this treatment of the subject is that very often accounts of acute intestinal obstruction fail to give sufficient prominence to the conditions for which such obstruction may be mistaken, and therefore, as the subject put before us to-night is the early diagnosis of acute intestinal obstruction, I thought the most practical way to attack it would be first to mention the conditions which I have known to be mistaken for it, especially as the best way to prevent mistakes in diagnosis is to be aware of their possibility.

[illegible]

most instances of confusion acute appendicitis is mistaken for intestinal obstruction but not of the most acute variety, rather than that the converse mistake is made. The following is a case in point. One Friday evening I saw with Dr. Slater-Jones a man, aged 60 years, who gave a history of severe attacks of colic, once accompanied by jaundice. On the previous Wednesday evening he was suddenly seized with a severe rigor. Dr. Slater Jones soon arrived and found the patient extremely collapsed with a temperature of 104° F. The next morning it was 99° and normal in the evening, there was some abdominal pain but it was across the top of the abdomen, he was sick twice, and we were told that the bowels had been opened on this day. On Friday he was sick only in the morning and when I saw him in the evening the abdomen was uniformly moderately distended without any dulness, tenderness, or other sign to indicate local disease. The distension made me fear we should have to open the abdomen later but as the pulse was very good, he did not look ill, his temperature was 98°, and he said that he felt better, we decided, as it would have been very difficult to arrange any operation that night, to leave him till the morning, believing that if he continued to improve we should have to conclude he was suffering from gall-stone colic without jaundice or from abdominal influenza. I heard early Sunday morning that he was not so well, therefore Mr. Charters J. Symonds joined us and we learnt that on Saturday there had been frequent very foul stercoraceous vomiting and that we had been misinformed about his bowels—they really had not been opened, not even any flatus being passed, since Wednesday in spite of several enemata. His pulse was 110 and of good volume; he looked well; and his temperature was 98°. His abdomen was distended uniformly without any indication of local disease but we decided upon operation because of the obstruction and continuing distension. We all thought the most likely diagnosis was that there was a gall-stone impacted in his ileum but operation showed a small abscess around the appendix in which a slough had led to a perforation; the peritonitis was not general. Here was a case in which severe and absolute constipation, distension, and stercoraceous vomiting were due to appendicitis which, on the other hand, did not give any indication of its presence and in which the initial rise of temperature only lasted 24 hours. We did not forget that an examination of the blood might have helped us but unfortunately I had not any of the necessary apparatus with me when I arrived at the patient's house. In another case of doubt I have known the presence of leucocytosis correctly turn the balance in favour of an abscess connected with the appendix.

It will be noticed that the case of appendicular abscess [illegible] just recorded, unlike as it was [illegible] did not lead to a diagnosis of [illegible] obstruction of a more chroni[illegible] and I think it is extremely rare for the localised peritonitis, caused by disease of the appendix, to be mistaken for acute intestinal obstruction, but it is less rare for a mistake to be made between acute general peritonitis and intestinal obstruction and this is not surprising, for strangulation of the bowel renders possible the [illegible] of bacteria through it and therefore many cases of acute obstruction quickly become complicated by acute peritonitis, hence it follows that the difficulty of diagnosis is often less the earlier the case is seen, but, on the other hand, probably the symptoms of few diseases vary so much as do those of acute peritonitis. Speaking generally, absence of pyrexia and of leucocytosis is in favour of intestinal obstruction, so also is rapid distension of the abdomen, especially if coils of intestine in which peristalsis is visible can be seen; early and urgent vomiting quickly becoming stercoraceous is in favour of obstruction; the pain is often paroxysmal in obstruction, the abdomen is not board-like or very tender, and there is no cutaneous hyperæsthesia; the patient does not lie in the usual attitude of peritonitis but may bend forward, doubled up by the pain, and the abdomen moves with respiration until later in the disease than is the case with acute peritonitis. But it is essential to bear in mind that every one of these symptoms which have been mentioned as generally indicating obstruction may be met with in peritonitis in which there may be complete absence of the passage of fæces and flatus by the bowel.

---

[1] Being the introductory remarks at a discussion at the Medical Society of London on March 14th, 1904.

Volvulus is the form of intestinal obstruction which most resembles acute peritonitis, nor is this surprising, for owing to the large amount of bowel strangulated and the severity of the strangulation the bowel rapidly permits the passage of micro-organisms which set up peritonitis. Probably the chief distinguishing feature of volvulus is the distension of the abdomen which is, as a rule, much more extreme and rapid than with acute peritonitis and perhaps the pain is less severe and the temperature is lower in volvulus.

Acute hæmorrhagic pancreatitis is apt to be mistaken for intestinal obstruction; the form which it most nearly resembles is that due to acute strangulation of the small intestine but if the patient is suffering from acute pancreatitis the actual obstruction is not well marked, the bowels are often opened several times soon after the onset of the pain, although later they are constipated, there is no distension of the intestines, and as the case goes on the vomiting does not often become stercoraceous. Should the patient live long enough there are signs of a localised peritonitis and pancreatitis at the upper part of the abdomen, the chief being localised tenderness, a feeling of resistance, and later distension due to the formation of a localised abscess with its circumjacent peritonitis. Probably by this time the bowels have been opened again and slight pyrexia has supervened. Several cases of pancreatitis have been recorded as surviving and laparotomy has been undertaken under the impression that they were cases of intestinal obstruction, but there is no evidence that in such the operation has been of benefit; indeed, it may have turned the scale against the patient; but whether we shall become sufficiently sure of a diagnosis of acute pancreatitis to withhold exploratory laparotomy is doubtful but at any rate this is the goal to be aimed at. It need hardly be said that if a distinct abscess forms operation will be needed.

Perforation or rupture of any hollow viscus or cyst within the abdominal cavity may be mistaken for intestinal obstruction, especially strangulation of the small intestine, but the mistake is one of the least serious because immediate laparotomy is necessary for either perforation or obstruction. The difficulty is at its greatest when the previous history gives no suspicion that rupture might occur—e.g., there is nothing to lead us to suspect a gastric ulcer or an ovarian cyst. Our chief guides to correct diagnosis will be that the onset of the symptoms is more severe and sudden with perforation even than with strangulation of the small intestine by a band and symptoms of peritonitis supervene much more early with perforation. The vomiting is more likely to be severe and later to become stercoraceous in obstruction in which the pain is almost always referred to the umbilicus and local tenderness is no guide to the seat of obstruction but not infrequently local tenderness and pain are guides to the seat of perforation. The abdomen usually becomes immobile and distended earlier in perforation than obstruction.

Thrombosis and embolism of the mesenteric vessels both lead to symptoms which may closely resemble those of acute intestinal obstruction. Fortunately the conditions are rare, for nothing but harm can follow opening the abdomen. Usually there is some obvious cause for the trouble, as heart disease which might cause embolism or some intra-abdominal trouble which might cause thrombosis. The sudden abdominal pain—referred to the umbilicus in both cases—and the collapse are equally marked in vascular obstruction and intestinal obstruction, in both vomiting is early and may become stercoraceous but probably it is altogether a more striking symptom in intestinal obstruction. If a vessel corresponding to a large area of bowel is blocked abdominal distension will be earlier than in a case of acute strangulation of the small intestine but the characteristic symptom is the passage of much blood from the bowel and if the superior mesenteric artery or vein is blocked some blood may regurgitate into the stomach and be vomited. Sometimes the blocking occurs in the aorta and then if this be in such a situation that the mesenteric arteries are interfered with there will be in addition to the symptoms due to interference with the mesenteric vessels severe sudden cramp-like pain and loss of power in the legs. The diagnosis from intestinal obstruction is then of course easy. A patient recently under my care who was suffering from heart disease was suddenly taken with pain and complete loss of power in the legs, abdominal pain and collapse so severe that he died in ten hours in spite of treatment; embolism of the abdominal aorta implicating the mesenteric arteries was found. I need hardly add that if the renal arteries are implicated hæmaturia will be an aid.

Intestinal colic is a fruitful source of error and many a patient's life might have been saved if he had not been regarded as suffering from what is called "simple colic." I need not take up the time of a society such as this with the diagnosis of lead colic which I have seen mistaken for acute intestinal obstruction. I would only point out that severe vomiting is quite the exception in lead colic and that we too often neglect to look for lead in the urine. With regard to other forms of intestinal colic it is important to remember that very severe intestinal colic—restricting the term to pain due to some local irritation usually caused by an error of diet—is rare in adults, while, on the other hand, acute intestinal obstruction—except that due to intussusception which has its own special symptoms—is rare in children, so that the opportunities of confounding intestinal colic with acute intestinal obstruction ought to be few. It is other forms of abdominal disease—e.g., appendicitis—rather than acute intestinal obstruction which are often erroneously set down to colic. Still, the mistake does occur and it is mainly to be avoided by noting the severity of the symptoms. If the patient's abdominal pain is so severe that he—an adult—sends for a medical man who finds that there is no diarrhœa and that there is no obvious indication of any cause for the pain such as a renal calculus, lead, disease of the appendix, &c., but the symptoms are not severe enough to indicate certainly acute intestinal obstruction, nothing should then be done except to apply warmth to the abdomen and to give an enema if there has been constipation, but no opium, as that will mask the symptoms. On a second visit a few hours later it will usually be found, if the case is one of acute intestinal obstruction, that the severity of the pain, the collapse, the state of the pulse, and the frequent urgent distressful vomiting leave no room for doubt and the abdomen should be opened at once. In the cases under discussion usually the severity and frequency of the vomiting and the state of the pulse are the first symptoms to show that the cause of the pain is acute intestinal obstruction, later the patient's expression and his collapse show this disease, in which it will be borne in mind the pain is often relieved by vomiting.

Biliary and renal colic can hardly ever be confused with acute intestinal obstruction if care is taken. Here, again, the severity of the vomiting and the collapse together with the facial expression and the feeble rapid pulse met with in intestinal obstruction will prevent an error. I have known the abdominal pain in a patient who had ulcerative colitis with constipation lead to an erroneous diagnosis of intestinal obstruction.

Acute intussusception may be confused with severe diarrhœa in children but as a matter of fact the mistake can nearly always be avoided if sufficient care is taken. The detection of a tumour either in the abdomen or the rectum is, of course, conclusive and the sufferer from acute intussusception at first has bloody diarrhœa, later constipation supervenes, but he commonly at some time passes pure blood, whilst in the severe enteritis of children the motion, if blood is present at all, consists of fæces, blood, and mucus throughout and constipation does not supervene till the patient is convalescent. Even if the case of diarrhœa is so severe as soon to lead to collapse this is usually preceded by pyrexia and often in these cases there is frequent and severe vomiting, but this is not usually a striking symptom in intussusception unless severe constipation comes on early in the case. Cholera may closely resemble acute obstruction.

There are some conditions which are met with in women which may be difficult to tell from acute obstruction—namely, the twisted pedicle of an ovarian cyst, a ruptured ovarian cyst, a ruptured extra-uterine fœtation, a ruptured pyosalpinx, and hysteria. In the three cases of rupture these are really instances of perforative peritonitis and therefore all that has been said in connexion with the diagnosis of that from acute obstruction will apply here. I have seen a ruptured extra-uterine fœtation mistaken for acute appendicitis, for it led to a tumour and feeling of resistance on the right side, but the slight elevation of temperature and the signs of pregnancy soon led to a correct diagnosis. In the only case of a twisted pedicle of an ovarian tumour leading to difficulty that I have met with the presence of a palpable right-sided tumour which was tender led to a diagnosis of appendicitis, which was perhaps a pardonable mistake as the patient was only 12 years old. In most cases the locality of the pain and tenderness, with in some the detection of a tumour, will usually lead to a correct diagnosis from acute intestinal obstruction. I have known great care necessary to distinguish hysteria from acute peritonitis but hysteria does not simulate acute intestinal obstruction.

Lastly, in any case of severe pain in the abdomen we should think of pleurisy and pneumonia but when early in the course of either of these the symptoms are mainly abdominal they suggest peritonitis rather than obstruction. I have seen pneumonia thought to be peritonitis but never obstruction.

Having very briefly reviewed the conditions which may be mistaken for acute obstruction we pass on to the diagnosis of the kind of obstruction and here it is of fundamental importance to remember that the early symptoms of acute intestinal obstruction are caused by the strangulation of the bowel and not by its obstruction. This is illustrated by the fact that a volvulus of the large intestine gives very sudden acute and serious symptoms—because of the strangulation—while the symptoms of a complete obstruction—say, by a gall-stone—without strangulation are much less severe. Indeed, the more we think of it the less important does mere obstruction become. For example, I remember the case of a woman whose bowels had not been moved for a month, it was thought owing to the pressure of a huge renal tumour compressing the bowel, but the tumour was really a great mass of fæces blocking the descending colon. She was not acutely ill. We do not observe acute symptoms even in spite of prolonged constipation in the cases in which the intestine is compressed by peritoneal adhesions due to the various forms of peritonitis. Think of the state of the intestines all compressed into one mass, such as we see at a post-mortem examination on a case of chronic peritonitis, yet there are no acute symptoms. The other day I saw the abdomen opened for chronic obstruction; the intestines were all matted together, the bowels had been rarely opened, and only with the greatest difficulty, but there were no symptoms of acute obstruction. The upshot of this is that to diagnose the form of obstruction we must, if the *symptoms are severe and acute, say to ourselves the patient* has got some form of obstruction that is likely to be associated with strangulation—e.g., a band, internal hernia, volvulus, kinking, or anything that will strangulate the bowel, and he is not suffering from compression, stricture, or impaction of contents unless these are complicated by strangulation. It illustrates my point to remind you that intussusception is severe in proportion as the bowel is strangulated. It is true that if a large number of obstructions of the small intestine are contrasted with a large number of obstructions of the large intestine the symptoms of the former will usually be much more acute than of the latter but this has nothing to do with the position of the obstruction; it is because whatever obstructs the small intestine generally at the same time strangulates it. Usually speaking, there are no acute symptoms unless there is strangulation and the symptoms of this are sudden agonising pain, often paroxysmal, referred to the umbilicus, frequent, early, distressful, and severe vomiting, a rapid, feeble pulse, apathy, pinched countenance, a normal or subnormal temperature, and collapse so severe that a previously *healthy man may in a few hours be at death's* door, hence when these exist we infer that the bowel is strangulated and it would be more accurate to diagnose such a case as acute strangulation of the bowel rather than as acute intestinal obstruction, for as already mentioned, these symptoms only enable us to diagnose strangulation of the bowel irrespective of the seat or cause of the strangulation. If there is great and rapid distension in addition to the symptoms of strangulation we infer a volvulus; if there is history of chronic obstruction—e.g., that due to malignant growth in the large intestine—the distended bowel behind the obstruction has become kinked or strangulated in some way; there may be other evidence of intussusception; or if, as is usually the case, we decide none of these are present and there is no external hernia, then, arguing from the experience of the post-mortem room, we learn that the small intestine is almost certainly the seat of the strangulation, a view which is supported if thus early in the case there is not much intestinal distension, for distension in such a case is partly due to obstruction of the bowel above the strangulation—but in strangulation of the small intestine there is not much of this—and partly due to paralytic distension of the strangulated bowel, but usually when the small intestine is strangulated not much of it is affected. But when we have arrived at the diagnosis of strangulation of the small intestine we cannot from the symptoms say what part of it is affected or the cause of the strangulation. Our knowledge of morbid anatomy shows that the cause of the strangulation may be one of many, such as a band of some sort, an internal hernia, &c. Excluding external hernias internal strangulations are far the most important variety of obstruction to diagnose early, for (1) they are frequently of such a nature that the surgeon can completely relieve them; (2) unless relieved they will quickly kill; (3) they usually come in previously healthy adults in the prime of *life*; and (4) *there is usually* no *concomitant disease* likely to kill the patient.

Among intestinal obstructions belonging to the entirely different class in which there is no strangulation, obstruction of the ileum by a gall-stone is one of the most acute, but here the fact that the patients are nearly always women over *50 years of age while strangulation usually occurs in men* under the age of 50 years will be of help. Further, the acute symptoms already given as indicating strangulation are rarely so severe in obstruction by gall-stones with which, too, there may be a history of jaundice. As already mentioned, chronic obstruction as by a growth may suddenly give rise to very [illegible] When, as sometimes occurs, they show themselves suddenly in a case in which the growth of the bowel has given rise to no symptoms the diagnosis is very difficult. If acute symptoms supervene upon chronic obstruction there is almost certainly a stricture of the large intestine—and strictures of this are virtually always carcinomatous—for except gall-stones the only chronic obstruction of the small intestine is that due to compression of a large extent of bowel from some form of chronic peritonitis and this compresses so much bowel that strangulation behind the compression rarely if ever occurs. Perhaps this is the best place to mention that visible mapping out of the distended bowel is a most uncertain symptom, for it may be absent in obstruction or it may be present in cases in which no obstruction is present—e.g., peritonitis—and, again, it may be impossible to tell whether *it is the large or* small intestine which is distended. Variation in the amount of urine passed is *another symptom on* which but little reliance can be placed.

I am very fully aware of the numerous shortcomings of these opening remarks which have had to be brief owing to the limited time at my disposal, but they are only intended as a basis for discussion. Fortunately, at the bedside the *difficulties are* often less than they appear on paper.

Harley-street, W.

A CASE OF ECLAMPSIA TREATED BY THE ADMINISTRATION OF CHLOROFORM.

BY JOHN FREDERICK JENNINGS, M.B. LOND., F.R.C.S. ENG.,
LATE INTERN MIDWIFERY ASSISTANT, ST. BARTHOLOMEW'S HOSPITAL.

THE patient, who was a primipara, 23 years of age, was admitted into St. Bartholomew's Hospital at 10.45 P.M. on Sept. 10th in an unconscious condition with the history that she had been seen to fall out of a railway carriage on to the platform whilst the train was still in motion. On arrival at the hospital she was not only comatose but had no corneal reflex. The pupils were equal, her colour was good, the knee-jerks were increased, there was no paralysis or œdema, and she had no fits till fully an hour after admission. Her temperature was 97° F. and her pulse rate was 64. She was eight months pregnant and the fœtus was alive; no uterine contractions were apparent; the os internum admitted one finger easily. The urine contained about one-quarter albumin. At midnight twitching of the face was noticed. On Sept. 11th the course of events was as follows. At 12.20 A.M. three definite fits occurred, commencing in the face and following each other in rapid succession. The bowels were well opened by an enema. At 1 30 A.M. there were four more fits. At 1.45 A.M. the cervix was dilated with the finger, the membranes were ruptured, and a large quantity of liquor amnii was let out. Labour pains commenced and soon became strong. The patient was given chloral hydrate and potassium bromide without much effect; she also had saline enemata which she retained. A steam bath was given but appeared to increase the number and severity of the fits and did not produce sweating. Three-minim injections of hypodermic solution of morphine had no effect on the fits and made the general condition worse. The bowels were well opened with compound powder of elaterin and diaphoretics and diuretics were given.

During the 12 hours following admission the patient had 37 fits and her face became œdematous and bloated. Chloroform was given and had a markedly beneficial effect; the severity of the fits was diminished and the patient's pulse, complexion, and respiration improved. She was delivered by forceps at 1.40 P.M. on Sept. 11th; the child was small and apparently at about the eighth month. Considerable hæmorrhage followed the birth of the placenta. The fits still continued after the birth of the child till noon on the 14th. She had 39 fits before and 75 fits after confinement, a total of 114. From noon on the 11th till noon on the 14th she was kept more or less continuously under chloroform and it was noticed that if the chloroform was stopped the fits became more frequent and more severe. Not only so, but chloroform was found to improve the pulse, the respirations, and the colour of the face. After the birth of the child the urine increased in amount (the patient was taking ammonium acetate and potassium citrate) up to 85 ounces per diem and the albumin diminished till only a faint cloud was present. She did not properly regain consciousness till the 16th, though she had asked at times for various things she desired. Both mother and child have since done well.

It is interesting to note in this case the excessive number of the fits and the beneficent effect of chloroform as compared with the apparent inefficacy of the various other remedies which were tried. In round numbers, the daily relation between the number of the fits and the quantity of urine which was passed was as follows: on the first day, 70 ounces of urine and 25 fits; on the second day, 85 ounces of urine and 15 fits; on the third day, 55 ounces of urine and 45 fits; and on the fourth day, 30 ounces of urine and five fits.

I am indebted to Dr. W. S. A. Griffith for permission to use the notes of this case.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON TWO CASES OF RODENT ULCER TREATED BY RADIUM.

By A. Stanley Green, M.B, B.S. Lond.

The following notes of two cases of rodent ulcer seem to me to be of sufficient interest for publication as both of them yielded to the action of radium after resisting the action of the x rays for a lengthened period.

Case 1.—The patient was a married woman, aged 75 years, who came to me with a rodent ulcer attacking the right ala nasi, extending upwards on the septum and the external wall of the nose and affecting the anterior end of the inferior turbinate. She had undergone three operations; the last one had involved the labio-nasal fold and a portion of the incision had remained unhealed and was now ulcerating. The discharge from the nose was troublesome and caused irritation of the upper lip. The x rays were applied for eight weeks every second day, the time of exposure varying from five to 20 minutes. The ulcerated surface in the labio-nasal fold rapidly healed under their influence, but no impression was made on the rodent ulcer which progressed along the septum slowly but surely. On July 2nd she went home, promising to return in a month, but it was September before I saw her again. The portion which had healed looked very well and was quite sound, but there was no improvement in the nose. For one month I gave applications of the high-frequency current, my thumb acting as the electrode. As there was no improvement I tried applications of radium bromide in a glass tube, the tube being held within the nose for periods varying from five to 20 minutes every second day. Progress was very rapid and in three weeks the ulcerated surface was soundly healed and remains so up to the present.

Case 2.—The patient was a man, aged 65 years, who had been suffering from a rodent ulcer on the right side of the scalp for the past two years. He had put off treatment and the ulcerated surface was of the size of a shilling and was slowly increasing in area. The x rays were tried and exposures varying from five to 20 minutes were given every second day for one month without any improvement. The patient went away for six weeks and returned with the ulcer in the same condition as before. Two more exposures of 20 minutes were then given, but owing to a severe attack of influenza he was compelled to interrupt the treatment for five weeks. I then commenced the application of radium bromide, the tube being held up against the ulcer for 15 to 20 minutes. Seven exposures were given in a month. The ulcer was then quite healed and the rapidity of the healing after the application of the radium was in this case most striking.

Lincoln.

A CASE OF UNUSUAL DISLOCATION OF THE CLAVICLE.

By Arthur C. Bird, M.R.C.S. Eng., L.R.C.P. Lond.

The following case being one of extreme rarity seems to be well worth recording. The patient, who was a man aged 38 years, met with an accident while riding a bicycle from an adjoining village to his home on the evening of Jan. 1st. He was somewhat under the influence of alcohol and was also carrying a bag of vegetables on the lamp crook of his machine, which was placed just below the handle bars and over the front wheel. On descending a hill the front wheel turned somewhat and caught in the bag of vegetables. The man then fell off on to his left shoulder and head and became unconscious. He was taken home in a cab and did not recover consciousness for some time, but when he did he complained of great pain and inability to move his left shoulder. When I saw him he was in a semi-conscious condition with his pupils reacting sluggishly to light and to accommodation. On examining the left shoulder I found that the left clavicle had been dislocated backwards and torn from the acromion process of the scapula. On dipping my fingers behind the acromial end of the clavicle, I could, with some force, bring the acromial end forward and downward into position, but on releasing my hold the acromial extremity (or, to be more correct, the whole clavicle, for there was no fracture) was immediately pulled backwards by the trapezius muscle. That night I gave him five grains of calomel, put him on a fever diet, and had ice applied to his head. On Jan. 2nd he was removed to the Victoria Cottage Hospital, Sidmouth, and was kept quiet, and on the 3rd his general condition was so much improved that I decided to endeavour to obtain permanent reduction of the dislocation. Nitrous oxide gas and ether having been given by Dr. G. A. Leon of Sidmouth, I easily managed to bring the acromial extremity down into position and having applied a flannel spica bandage I doubled up a firm sponge and placed it on the top of the acromial end of the clavicle and then put on a Bavarian plaster-of-Paris shoulder cap which completely covered the sponge. With a large pad in the left axilla and the left arm in the Sayre's position for ordinary treatment of fractured clavicle, I managed to make the chief pressure over the left shoulder and under the left elbow with, of course, occasional turns round the body. The patient left the hospital in a few days. The shoulder was kept in this splint for five weeks and when the splint was removed at the end of that time the injured shoulder was found to be perfectly symmetrical with the other one and all the parts were in excellent position. Passive movements were then employed, with the rubbing in of liniments, and the patient now (Feb. 22nd) has excellent mobility in his left shoulder-joint and is able to use his arm well. It is probable that the superior and inferior acromio-clavicular ligaments, as well as the conoid and trapezoid ligaments, were ruptured.

Sidmouth.

A CASE OF SUBMAXILLARY ABSCESS FOLLOWED BY FACIAL PARALYSIS.

By JAMES C. MCWALTER, M.D. BRUX., F.F.P.S. GLASG.

So seldom is it that the relation of the seventh nerve to the chorda tympani and the salivary secretion can be pointed out as a cause of death that an account of a case where the connexion seems unequivocal may be worthy of record.

The patient was an infant, aged about five months, and the mother brought her to me for an ordinary scrofulous abscess situated under the jaw. The child was otherwise healthy and well nourished and the swelling was ordered to be poulticed. This instruction was carried out too faithfully by the mother, who continued it after the abscess discharged, neglecting to bring back the child meanwhile. When the raw surface began to heal she was alarmed by the extraordinary contortion of the child's features when in the act of crying, and coming to me in terror she was told that the child had facial paralysis of which all the typical signs were present. The contraction of the scar from the abscess had evidently involved some fibres of the facial nerves but treatment was now unavailing to restore it although continued for some weeks Shortly afterwards symptoms of involvement of the secretory fibres became manifest and the infant commenced to waste away. The mother, believing that the breast milk was not agreeing with the child, fed her on cow's milk and the wasting became still worse. The infant seemed to lose the desire for nourishment, the power of sucking, and the function of assimilation, though without any evident lesion other than the involvement of the seventh nerve. She became gradually weaker and died apparently from sheer lack of nutrition.

MIDDLESEX HOSPITAL.

A CASE OF FOREIGN BODY IMPACTED IN THE LEFT BRONCHUS; REMOVAL BY OPERATION.

(Under the care of Dr. W. PASTEUR and Mr. T. H. KELLOCK)

A SCHOOLBOY, aged five years, was admitted into the Middlesex Hospital on Sept. 28th with the following history. On the 23rd he brought home a small glass stopper which he had picked up in the street and showed it to his mother. A few minutes later the father called her back to the room which she had just left to find the child lying on the floor "fighting for his breath." His face and lips were blue and his eyes were "starting." Guessing that he had swallowed the stopper she picked him up by the heels and shook him violently with marked relief to his symptoms, but the stopper did not reappear. He was at once taken to the hospital, x-rayed with a negative result, and as he was then breathing quite quietly allowed to go home again. On the 27th he was seen by a local practitioner who discovered physical signs at the apex of the left lung which he attributed to impaction of the glass stopper in the bronchus leading to the upper lobe. On admission the boy looked ill. His temperature was 102·8° F. and his complexion was pale and slightly dusky. The respirations were 36 per minute, but not laboured. The alæ nasi moved slightly. There was no stridor during ordinary breathing but with cough or deep breathing there was a stridulous wheezing sound. The cough was loud, inclined to be brassy at times, and decidedly paroxysmal. The pulse was 110 and the urine was normal. On examining the chest there was marked loss of movement on the left side, which felt smaller than the right. The heart's apex beat was in the fifth interspace in the nipple line. The percussion note was a trifle short over the left upper lobe but there was no dulness. Vocal fremitus was impaired over the left front as low as the level of the fourth rib and behind in the suprascapular region and part of the interscapular region. The breath sounds were very weak all over [illegible] entirely lost the vesicular qual[illegible] much weaker than normal over [illegible] than over the apex. The voice sounds were audible but weak and distant all over the left chest. With the exception of an occasional rhonchus there were no adventitious sounds. The right lung was healthy. Dr. Pasteur saw the child on Oct. 1st and at once asked Mr. Kellock to see him. Mr. Kellock recognised the boy as having been under his care a few months before for an injury to the hand. At that time he was healthy and robust looking and Mr. Kellock was much struck with the change in his appearance. The child was again examined with the screen when it was noticed that there was practically no movement of the ribs on the left side in respiration Dr. Pasteur and Mr. Kellock were unable to see anything in the region of the left bronchus but Mr. C. R. C. Lyster fancied he could detect a faint shadow in that situation. Dr. Pasteur and Mr. Kellock agreed that in the face of such a definite history and with physical signs so pointedly suggesting obstruction of the left bronchus an attempt to relieve the condition by operation should at once be made, the more so that the oscillating temperature and serious illness of the child made it probable that local [illegible] taking place

[illegible] probe downwards and into the left bronchus a foreign body was distinctly felt and on measuring the distance it was found to be about three and a half inches from the lowest part of the opening in the trachea. Attempts were made to dislodge it by means of the probe but they were unsuccessful as was also an attempt to grasp it by means of long forceps. A piece of silver wire twisted into a loop at the end was then tried, passed down to the foreign body, and rotated Whilst this was being done the child rather suddenly coughed up about one drachm of thick pus. On the next attempt the wire evidently got beyond the foreign body and dislodged it, for it was seen with a good deal of mucus to emerge from the wound for an instant but was sucked back again at once on an inspiration occurring. Fortunately, it was found on examination to have returned to its original situation; a rather stiffer loop of wire was passed down to and beyond it, on withdrawing which the glass stopper was delivered through the wound. The pus and mucus having been thoroughly cleaned away from the wound, the opening in the trachea was closed by fine silk sutures passed through the intervals between the cartilaginous rings but not entering the lumen, the muscles were brought together by one or two fine silk stitches, a small drainage tube was put in the lower angle of the wound reaching nearly to the sutured trachea, and the skin wound was closed round this by means of interrupted horse-hair sutures. A light dressing was applied and the child, who had borne the operation very well, was sent back to the ward. The neck was dressed on the second day and the drainage tube was removed; there had been very little discharge through it and the upper part of the wound had practically healed. Five days later, the wound having quite closed over, a little fulness was noticed at the lower part; this was reopened with a probe and a few drops of pus were let out and complete healing took place a day or two after this. There was never any escape of air through the wound. There was a marked diminution of symptoms from the time of operation onwards. The temperature, which before operation had been high and irregular, fell at once and remained normal. The cough immediately lost its paroxysmal character but persisted for several days. The condition of the lung rapidly improved and, beyond slight impairment of movement, the physical signs were practically those of health by the end of the fourth day. There was a striking change in the child's colour and general condition and he continued to make good progress up to the date of his discharge on Oct. 26th.

Remarks by Dr. **Pasteur** and Mr. **Kellock**.—The features of interest in this case are mainly surgical. We were fortunate in obtaining so definite a history that there could be no reasonable doubt as to the cause of the obstruction. The x-rays screen examination only gave an indefinite shadow in the region of the left bronchus. After removal the stopper was found by Mr. Lyster to offer a resistance to the x rays equal to nine centimetres aluminium, which will only give an indefinite shadow through the thorax of a child about this age. Measurements taken at the time of the operation and subsequently applied to the trachea of a child of about the same age showed that the foreign body must have been lodged just at the bifurcation of the left bronchus.

It is worthy of note that a foreign body such as was found in this case should have given rise to the formation of an appreciable amount of pus in the course of a few days. Septic changes would not have been surprising had it been an organic body capable of decomposition or of such irregularity of surface as to be likely to cause ulceration. From the absence of blood in the pus that was liberated and the rapidity of recovery we conclude that the pus in this case had been pent up in one of the larger bronchial tubes rather than in a cavity caused by ulceration.

The operation itself calls for little comment. It was evident that we had to deal with a foreign body impacted in the bronchus and there was so little likelihood of its being coughed up on opening the trachea that an opening as low as possible seemed desirable. On ascertaining that the body was lying some way down the left bronchus and after an unsuccessful attempt to reach it with tracheal forceps, these were abandoned in favour of a twisted loop of wire similar to that successfully used by Mr. Kellock in a previous case for the removal of an impacted haricot bean in the left bronchus. The modern plan of completely closing the trachea by sutures was attended with complete success.

ROYAL BERKSHIRE HOSPITAL, READING.

TWO CASES OF THROMBOSIS.

(Under the care of Dr. **Francis H. Hawkins**.)

For the notes of the cases we are indebted to Dr. W. T. Scott, house physician.

Case 1. *Multiple thrombosis; embolism of the middle cerebral artery; death.*—The patient, a married woman, aged 33 years, was admitted on Oct. 15th, 1903, into the Royal Berkshire Hospital, Reading, under the care of Dr. Hawkins, complaining of pain and swelling of the left leg. She had never suffered from any definite illness but for some time past had felt "out of sorts." She had had three children, the youngest being two years old. Labour was in each case normal. One month previously she had pain in the calf of the left leg which was followed by some swelling. Soon after she had a sudden severe pain round the lower part of the chest, lasting for three days. A week previously she began to complain of pain in the left leg, especially in the groin, and the limb became swollen. For a fortnight before admission she suffered from profuse perspirations. There had been no cough.

On admission the patient was dark-haired, of medium height, somewhat spare, with slight flushes over the malar bones and an anxious expression. The whole of the left leg was œdematous and pitted on pressure except over the dorsum of the foot, where the œdema was very fluid and fluctuation could be obtained. Tenderness was most marked in the groin, behind the knee, and over the calf of the leg. There was no pain or swelling of the right leg. The heart was normal in position and there were no murmurs. No abnormal physical signs were observed on examinatian of the lungs. The abdominal and pelvic organs appeared to be normal. The urine gave an acid reaction; it had a specific gravity of 1018 and contained no albumin or sugar. A blood examination gave the following results: red blood corpuscles, 4,200,000 per cubic millimetre; white blood corpuscles, 9000 per cubic millimetre; and hæmoglobin, 80 per cent.

For the first ten days after admission the patient's condition steadily improved, the tenderness and swelling of the left leg gradually disappearing. She complained of a troublesome cough occasionally but no abnormal physical signs were detected in the lungs. On Oct. 25th at 5 A.M. when visited by the nurse she was quite comfortable and remarked what a good night she had passed but feeling thirsty she asked for a glass of water. When the nurse returned with this a minute or two later she found the patient crying and unable to speak. On examination it was noted that the patient was not unconscious; there was no stertor, the pupils were equal, the mouth was drawn over to the left, the tongue was protruded to the right, and there was paralysis of the right half of the occipito-frontalis muscle. The right arm and right leg were completely paralysed and the knee-jerks were absent. The pulse was of low tension. On the 26th the patient seemed brighter and two days later could say "yes," answering "yes" to all questions but if she meant "no" shook her head after saying "yes." The swelling of the left leg had nearly disappeared when on Nov. 2nd, eight days after the hemiplegic attack and two months after the left leg began to swell, the right leg became tender. On the 3rd the right leg was very tender and œdematous. This condition increased and the whole of the leg and thigh became very swollen. Three days later the swelling began to subside but the dorsum of the foot became red and tender with some lymphangitis. The patient's condition gradually improved and she tried to say something besides "yes" but was usually quite unintelligible. The knee-jerk became exaggerated and ankle clonus was readily obtained during a few days. On the 17th, 15 days after the right leg became œdematous, there was tenderness over the left brachial veins but no œdema of the arm or the hand. A thrombus could be distinctly felt in the left brachial and median basilic veins. At this time the patient became much distressed, her pulse was 140, and her respirations were 45, a condition which continued until her death. On the 22nd, five days after the left arm, the right hand was noticed to be œdematous and just below the elbow there was marked tenderness. Three days later the right hand and forearm were very swollen, the œdema over the dorsum of the hand being so fluid as hardly to pit on pressure. The patient's condition gradually became worse, the abdomen became greatly distended, and death occurred on Dec. 6th. The temperature throughout the illness hardly rose above normal until the last fortnight, when the evening temperature was usually about 101° F.

Necropsy.—At the post-mortem examination the left pleural cavity contained a moderate effusion of blood-stained serum. A large recent infarct was present at the right apex of the lung, as well as several smaller infarcts in the left lower lobe. The left lung was partly collapsed. The heart contained several small ante-mortem clots in the ventricles and auricles, one being adherent to the mitral valve. There was no mitral stenosis. The liver showed some passive congestion. A large not very recent infarct was found in the spleen. A small infarct was present in each kidney; both were beginning to cicatrise. The intestines were dark and congested. The internal saphena veins in both legs and the femoral vein in the left leg were blocked. There was marked œdema of the right arm below the level of the insertion of the deltoid muscle. There was a large area of softening in the region of the internal capsule of the brain on the left side.

Case 2. *Thrombosis with extravasation of blood in the left lower limb; gangrene; amputation; recovery.*—The patient, a married woman, aged 50 years, was admitted on Nov. 12th, 1903, into the Royal Berkshire Hospital under the care of Dr. Hawkins, complaining of pain and swelling of the left leg. She had been anæmic since the birth of her youngest child, 14 years previously. The labour was natural and there was no excessive hæmorrhage. She had not felt short of breath or noticed any swelling of the feet but always felt weak and tired. She stated that the pain and swelling in the leg began rather suddenly a week before admission. During the first four days she had continued her work but at the end of that time the swelling became much greater and the pain more severe and she had to take to her bed.

On admission the patient was a very pale woman, rather emaciated, with dark hair turning grey. The whole of the left lower limb was very œdematous and pitted on pressure except over the dorsum of the foot where the œdema was very fluid. There were much pain and acute tenderness, especially in the groin, behind the knee, and at the inner side of the tendo Achillis. From the knee to the heel on the inner side and the front of the leg there was a mark resembling a large bruise, being green and purple in colour. There were similar but smaller marks behind the knee and behind the trochanter. There were also red purpuric patches scattered over the same areas, while the region behind the malleolus was of so vivid a blue that it looked as though it had been stained with methylene blue. The heart was normal in position; a systolic hæmic murmur could be heard over the pulmonary cartilage. No abnormal physical signs were detected in the lungs and the abdominal and pelvic organs appeared to be normal. The urine gave an acid reaction and had a specific gravity of 1020; it contained no albumin or sugar. A blood examination gave the following result: red blood corpuscles, 2,500,000 per cubic millimetre; white blood corpuscles, 22,000 per cubic millimetre (neutrophile cells 80 per cent.; lymphocytes and hyaline cells, 20 per cent.); and hæmoglobin, 28 per cent.

During the first fortnight the pain and swelling gradually diminished but several blebs formed over the inner side and back of the leg. On Nov. 26th it was noticed that the toes of the left foot were dark in colour and rather shrivelled. There was absence of sensation, tactile and painful, over the lower third of the leg and over the foot. She complained that the foot felt numb. During the next few days the foot and ankle became gangrenous and by Dec. 1st a line of demarcation began to form about the middle of the leg. The foot was then quite black and dry but the lower third of the leg was moist and gave out an offensive odour. The pulsations of the popliteal artery could be easily felt and operation was postponed so long as the patient's general condition remained good in order to allow the œdema of the thigh to disappear as far as possible. On the 3rd the patient began to complain of severe pain in the leg and her temperature, previously normal, rose to 101° F. Immediate operation was therefore decided on. Amputation of the limb through the middle of the thigh was performed by Mr. W. J. Maurice. At the point of amputation a blood clot of the size of an orange was found lying in a *distinct capsule in the* neighbourhood of the large vessels. The wound healed by first intention and the patient made a good recovery.

Remarks by Dr. HAWKINS.—The first case recorded is interesting: (1) clinically in showing venous thrombosis in all four extremities and in œdema being present in three but absent in one (the left arm) and it illustrates the fact that venous thrombosis may occur without producing the consequences more frequently met with; and (2) pathologically in having a thrombus on the posterior cusp of the mitral valve. There was no stenosis of this valve. This thrombus on first sight gave somewhat the appearance, except in colour, of the vegetative excrescences of a malignant endocarditis; it, however, peeled off with some pressure, showing the underlying surface to be normal in appearance but of the colour of a port-wine stain. To this or to the other smaller thrombi were due the emboli in the brain, the lungs, the kidneys, and the spleen. From the examination of the blood nothing definite could be determined as to the cause of the thrombi so that one can only suggest that they were the *product* of blood stasis consequent *on debility.*

The second case is recorded as illustrative of gangrene following venous thrombosis with blood extravasation (unfortunately the vessels of the amputated limb were not examined, the limb being disposed of before an examination could be made), but during the time the case was under my observation I so regarded it. However, the possibility of such has been much discussed and I may be wrong in so describing it, but I would suggest that the pressure of a blood clot due to the venous thrombosis pressed upon the arteries and so caused the gangrene. From the facial aspect of this patient, the yellowy, almost lemon tinge of the skin of the face and the trunk, the pale lips and pearly conjunctivæ, the case might have been thought to be one of chlorosis, pernicious anæmia, or malignancy. My own view was that the case was one of chlorosis associated with venous thrombosis, and the blood showed a considerable deficiency of hæmoglobin, but a further examination made by Dr. Scott showed a considerable increase in the white corpuscles and a relative increase of neutrophile cells which suggest a secondary anæmia.

GENERAL INFIRMARY, WORCESTER.

A CASE OF CHRONIC INTUSSUSCEPTION DUE TO MULTIPLE POLYPI OF THE INTESTINE.

(Under the care of Dr. MABYN READ.)

FOR the notes of the case we are indebted to Dr. P. G. Harvey, house physician.

An unmarried woman, aged 22 years, was admitted for the second time to the General Infirmary, Worcester, under the care of Dr. Mabyn Read, on June 4th, 1903, with the following history. On May 20th, 1903, she was sick and had some pain in the abdomen, chiefly on the left side. After her bowels had acted "something came down" from the rectum and could not be replaced. This protrusion was seen by a medical man who kindly informed Dr. Harvey that it was a large prolapse of the rectum which was covered with numerous dark, exceedingly brittle stalked polypi, many of which broke off on replacing the prolapse but some were returned with it. The next day she was admitted to a surgical ward at the Worcester Infirmary and was examined and kept under observation for a week, but nothing abnormal being found and no symptoms occurring she was discharged. No polypus was felt. On May 31st she began vomiting again and had abdominal pain; the bowels acted regularly and frequently. This continued until admission, the sickness tending to get worse. With regard to her past history the patient had never been strong and had attended at the Worcester Dispensary for some six or seven years for loss of flesh. She had had no attacks like the present one before May.

On admission the patient was very emaciated and looked ill. The tongue was dry, red, and coated with a dry-brown fur. The temperature was 99·2° F. and the pulse was 100. As to [illegible] he liver dulness [illegible] The abdomen [illegible] nd under the costal arch. Active peristalsis was observed in the distended portion of the abdomen. There were very little tenderness and no rigidity of the abdomen. Pain was worse when the bowel contracted. From its situation the distended and contracting bowel was supposed to be the transverse and descending colon. Per rectum the mucous membrane felt relaxed; nothing abnormal was felt in the rectum. In Douglas's pouch a tender moveable body was felt which was supposed to be the body of the uterus from its size and position. (The patient was menstruating at the time.) The urine was of specific gravity 1026 and acid; there was nothing abnormal. The case was looked on as probably one of a polypus high up in the sigmoid flexure. The patient was put on a fluid diet and had fomentations applied to the abdomen and a bismuth mixture to try to check the vomiting. On June 5th she was sick twice during the night; she vomited curdled milk. Milk was stopped and meat essence and broth were given. She was sick once after the change of diet. There were much less pain and distension of the abdomen and peristalsis was not observed. The bowels acted well after an enema. On the 6th, 7th, and 8th the patient continued to improve. There was no sickness and there were less pain and distension of the abdomen but slight tenderness was present in the right iliac region. On the 10th the patient was again sick and it was decided to examine her under an anæsthetic but nothing was found in the abdomen or the rectum. Her general condition greatly improved, the bowels acted naturally, and on one occasion she had eight motions in the 24 hours (July 4th). On the 7th, when the rectum was again examined, clear mucus was found on the finger after examination. On the 11th she was again examined under an anæsthetic but nothing further was discovered, a good deal of clear mucus being observed. The rectum was washed out daily with two pints of boric lotion, a good deal of shreddy mucus in flakes of about two inches in length being returned. By Sept. 23rd she had considerably improved but had had six attacks of sickness during the two months; the shortest lasted one day and the longest four days. The vomited material was chiefly food but on one occasion contained bile. The abdomen was never distended to the extent it was on admission but there were decided fulness and some tenderness on the left side. An indistinct band was felt on the 23rd extending across the left side of the brim of the pelvis and it was thought it might be due to an adhesion. She had so far improved as to be able to take ordinary food and to get out of doors. On Oct. 6th she had an attack rather more severe than usual. The abdomen became a good deal more distended and, as on admission, the distension was chiefly on the left side, where a coil of gut in active peristalsis was observed. The patient was put on nutrient enemata of peptonised milk and the rectum was washed out every morning, fæcal material and some shreddy mucus being obtained. Nothing was felt by the rectum. On the 9th the vomit was fæcal in smell and dark brown in colour. Her condition was getting steadily worse and she was seen in consultation by one of the honorary surgeons at 1 P.M. and it was decided that she was suffering from subacute obstruction probably due to a polypus in the sigmoid flexure or perhaps to the band which had been noted on Sept. 23rd. If her symptoms did not improve it was arranged to perform a laparotomy, but it was decided to wait a little longer as she had had several attacks before and to operate during a quiescent period if possible. At 5 P.M. she returned a large quantity of peptonised milk representing three or four nutrient enemata from the rectum and became very collapsed. Dr. Read was summoned and it was decided to operate at once but the collapse increased and she died at 6.30.

Necropsy.—The post-mortem examination was held on Oct. 11th. On opening the abdomen the first thing to attract attention was a coil of greatly distended *small* intestine lying in the left flank, to which were adherent omentum and some collapsed small intestine. On separating the adhesions some pus was found which was confined to the left side by a band of omentum which was adherent to the pubes and the brim of the pelvis. A small rupture was found in the *small* intestine through which an intussusception could be seen. After removing the intestines and opening them a large polypus was found near the duodeno-jejunal junction; about two feet down the jejunum was the intussusception which was about six inches in length, at the apex of which was a large polypus. There was a smaller polypus about half way up the entering layer of the intussusception. There was a large collection of polypi in the cæcum and lower part of the ascending colon and there were three smaller ones in the transverse and upper part of the descending colon. No polypi were found in the sigmoid flexure or rectum.

Remarks by Dr. HARVEY.—The above case may be of interest on account of the length of time the illness lasted, the indefinite and in fact somewhat misleading nature of the symptoms, and the unusual condition found post mortem. I am greatly indebted to Dr. Read for permission to publish the notes of this case.

to undergo combustion in the body. They had there, then, in the pancreas apparently a double secretion, one of which they might term the external secretion, as distinguished from an internal secretion where the fluid from the gland was not poured out upon a free surface but into the blood. Apparently those two secretions were dependent upon different parts of the pancreas. In the case of diabetes they seemed to have a disease depending upon failure of the internal secretion but his own experiments to supply a glycolytic ferment in cases of diabetes although not entire failures were comparative failures. The most striking of all the internal secretions, however, was that of the thyroid gland. He had occasion once to see nearly all the symptoms of exophthalmic goitre with the exception of the enlargement of the thyroid and the protrusion of the eyeball produced by an overdose and over-long continuance of thyroid administration for myxœdema. Most of the symptoms of exophthalmic goitre were due to actual poisoning by the internal secretion. In cases of exophthalmic goitre he used to depend very much upon bromides and upon lime in one form or another, and sometimes he seemed to see good results from those; but the results were not so well marked or pronounced as one would have liked. He had since tried extract of suprarenal capsule and that he thought produced a certain amount of benefit. He had tried thymus but his results had not been very good with that either. Extract of suprarenal capsule had an almost entirely different action upon the blood-vessels and upon the heart from the extract of thyroid. The latter was one of the most marked vaso-dilators he knew and it had been exceedingly useful where they had the fingers becoming dead in winter time and where the patients suffered much from chilblains. By putting them upon small doses of thyroid extract they got the vessels of the fingers dilated and chilblains thus prevented. Extract of suprarenal capsule contracted the vessels to an enormous extent and also stimulated the heart; so between the two they got the blood pressure very much raised indeed; in fact they knew no drug which would raise the blood pressure to such an extent as suprarenal capsule, except nicotine, and one did not know at present whether the nicotine which people took in smoking might not be an adjunct to the action of the suprarenal capsules in keeping up the blood pressure and so keeping up the general tension and power of the individuals. But another question arose in connexion with the agitation in relation to youthful smoking. If suprarenal extract counteracted the effects of thyroid might not nicotine to a certain extent? One of the uses of thyroid was to increase growth. Its effects were more marked in cretinoid dwarfs than in others but he had seen a marked growth following in a child who was not cretinoid by the administration of thyroid extract. Probably it would be said that that was *post* and not *propter hoc*. But he thought it was *propter hoc*. And the idea occurred to him that it was possible that juvenile smoking might have the effect of counteracting the effect of some of the glands which would tend to cause growth and thus to stunt the growth of the child. But it was the pituitary body which seemed to be the gland which regulated the growth of the child and disease of that was often followed by acromegaly and also by the enormous growth of the patient, so that he became a giant. Ovarian extract had been used, especially in cases of women at the menopause, and he thought he had seen sometimes a certain amount of benefit by giving ovarian extract in cases where women were complaining very much of the flushes of heat which were so common at the menopause; but even with that he had not obtained any very marked results. The kidney was another organ which seemed to have an internal secretion as well as an external one. With increased knowledge of the enzymes formed by the glands, of their reabsorption, the changes they underwent, and of how to get both enzymes and zymogens if possible, and if they could know how to split up those zymogens in the blood afterwards, then their powers of treating disease would be enormously increased.

Sir VICTOR HORSLEY said that after all the work which had been done on the thyroid gland, and after all the well-known clinical results obtained by the use of thyroid extract in a disease like myxœdema, they had rather got the idea clinically that when they considered an internal secretion and its alterations by disease they thought only of its banishment. With regard to the thyroid gland at the present time the idea of the internal secretion of that gland being altered by disease was simply that it came to an end. There was not merely that negative side of internal secretion, the positive side was as important clinically. The internal secreting glands when diseased were no longer able to furnish the useful ingoing ferment and in the process of becoming diseased poured into the circulation not merely a healthy ferment but aberrant and poisonous substances. In certain well-known conditions like simple goitre there was ample clinical evidence of such poisoning going on. The thyroid adjusted itself to the requirements of the organism chemically and prevention of that was seen in disease, especially in the formation of new growths. Exophthalmic goitre was a condition in which the thyroid gland was responsible for certain nerve symptoms and the clinical treatment of exophthalmic goitre at present was apparently based upon an attempt to treat the external secretion of the gland. There were few cases of exophthalmic goitre which could not be cured by systematic treatment with the faradic current carried out persistently. Many cases had been brought to him for operation in which operation had been avoided by the energetic use of the faradic current, not the constant current, as was sometimes used by mistake. Supposing the electrical treatment not to have produced a beneficial effect it was curious that in exophthalmic goitre the division of the isthmus by a surgical operation might stop the disease. There was one other condition in relation to the operative treatment of exophthalmic goitre which brought them to a very interesting conclusion with regard to internal secretion. When it was first proposed to operate in exophthalmic goitre people immediately took it up without considering the cases or without knowing exactly why they were doing the operation and the result was that a large number of deaths followed the operation. In such cases if most of the thyroid gland was removed the patient was practically brought to the same condition as a carnivorous animal from [illegible] thyroid gland had been suddenly removed and in [illegible] temperature rapidly rose if it were young, with [illegible] dyspnœa, and death. Such was exactly the same clinical picture in cases of rapid death after removal of one lateral lob[illegible] thalmic goitre. That was a p[illegible]ocesses in the gland, the abs[illegible] and also the existence of [illegible] adenoma of the thyroid gla[illegible] the condition was advanced there would be found symptoms of toxicity. The patients were being poisoned precisely in the same way as in exophthalmic cases, only in a much less degree. At the present time thyroid extract was frequently given in goitre. Thyroid extract given internally could not have any supplementation effect in the case where the new tissues were poisoning the patient already. On the contrary the patients often said it made them much worse. In parenchymatous goitre thyroid extract produced a beneficial effect for some time—it did not cure it or avert an operation ultimately but it made the patient better and it was easy to understand why it should. By giving the thyroid extract they were doing a judicious thing—they were supplementing the failure to the patient of his thyroid gland and providing against his athyroidism. And so markedly was that the case that where patients had not been treated in that way it was advantageous to treat them so for a certain time before operating, for by that means the athyroidal condition was reduced. They were familiar now with the fact that in malignant disease of the thyroid gland, however localised, it was absolutely essential to remove the whole gland. In those cases, although the gland was completely removed, the patients required exceedingly little thyroid extract to keep them in health. With an ordinary myxœdema patient the custom was to give thyroid extract daily but a carcinoma case did not require it. The thyroid gland which was such an extremely important organ in early life for the growth and development of the body became of very little importance every year after the age of 40 was passed, and most carcinomata of the thyroid gland began after the forty-fifth year. In other words, it was another proof of the quantitative relationship between that internal secretion and the needs of the body. Sir Victor Horsley concluded by suggesting that clinically they ought to look more than they did for the positive conditions accompanying aberrant internal secretion, for the poisonings which accompanied these secretions, quite as much as they looked for the loss of normal useful internal secretion.

Dr. H. D. ROLLESTON said that the theoretical consideration which naturally arose was the possibility that some of the diseases which were assumed to be due to disturbance of the normal internal secretion of one ductless gland, such as exophthalmic goitre, acromegaly, and possibly others, were more complex in their nature. In acromegaly glycosuria was not uncommon and had been shown to depend on changes in the pancreas; were those pancreatic changes secondary, like the splanchnomegaly sometimes seen in that disease? Or were they two concomitant changes? Acromegaly might be combined with exophthalmic goitre and there was some superficial resemblance between acromegaly and myxœdema. It might be argued that acromegaly was the result of a disturbance of the chemico-physiological equilibrium maintained in health between the internal secretions of those glands. An anatomical fact which suggested that there was some inter-relation between the diseases due to abnormal internal secretions was that the thymus gland, which underwent complete atrophy before adult life, was almost always persistent or rejuvenated in exophthalmic goitre and sometimes in myxœdema and in acromegaly. The want of success in the treatment of exophthalmic goitre and acromegaly might possibly depend on the fact that two or more glands instead of one only were in each case in an abnormal condition. In the last part of his remarks Dr. Rolleston referred to the therapeutic uses of suprarenal extract. Schäfer and Oliver had shown that the active principle was not destroyed by gastric juice *in vitro* and there was no doubt that when given by the mouth to patients with Addison's disease it raised the blood pressure. It was remarkable that when taken by healthy persons it did not raise the blood pressure. Preparations of the active principle were now available for hypodermic injection and the method was probably more effectual than administration by the mouth. The effect of treatment of Addison's disease by suprarenal extract or its active principle [illegible] as compared with the effects [illegible] Improvement often occurred [illegible] rare instances that the good effect was maintained and that anything like a cure was effected. In Adams's critical analysis of 105 cases of Addison's disease treated by suprarenal extract, the treatment had no effect in 49 cases, 33 cases improved coincidently with treatment, in 16 cases permanent benefit resulted, and in seven cases alarming or fatal results were produced by the treatment. Although suprarenal extract was not a marked success in Addison's disease it had been successfully employed as a local application to constrict the peripheral vessels in operations on mucous surfaces, such as the nose, eyes, &c., in capillary oozing, in hæmophilia, and in epistaxis. Crile had advocated its use in cases of pure surgical shock as a most satisfactory method of raising the blood pressure; he recommended that it should be injected intravenously in large quantities of salt solution, continuously and slowly.

Dr. A. E. WRIGHT said the secretions that he would speak about were those which were not elaborated by any gland. The substances he proposed to discuss were those which they all required daily. They were substances of which they did not know where they were created in the body, but they were present in considerable quantities in the blood. The most marked type of internal secretion was diphtheria antitoxin. All the protective substances involved in the cure of disease were to be regarded from the point of view of internal secretions. The blood of a man affected with acne was defective in a certain internal secretion. In a patient suffering from acne who was defective in his protective substances against that condition in the blood they did not know where to get those substances which were required. If they took a person who had recovered from disease they would find that he had got the power of elaborating the internal secretions required and though they could not supplement them they could if they knew the laws by which they were produced help the production of those substances in patients. He (Dr. Wright) might be considered venturesome if he said that there was no case of acne which could not be cured in a practically short time, but in his own experience there had not been one case which had not been curable, though his experience was only some 36 cases. There had not been one of them in which he could not produce enough internal secretion to kill off the staphylococcus. Patients with tuberculosis recovered if they produced enough of the internal secretion to render their bodies uninhabitable by the tubercle bacillus, and a serum had been used for the purpose of supplying this. The patient was put into the open air in the hope that he

Broadly speaking, in a disease of chronic character inclined to reinvade people, which was not immediately dangerous to life, there was an interval during which the secreting tissues in the body could be induced to secrete the substances required. Evidence could be got that they had been obtained, and in almost all cases, clinically, benefit would result. The effect of one inoculation in any disease was not sufficient to increase the amount of protective substances in the blood so as to change the whole nature of anybody. Ordinary inoculation was best carried out by a series of repeated doses, and they had to know the law which governed those repeated doses to secure success. The object of all inoculations was to produce by a series of repeated doses an internal secretion by accumulative effects. When they dealt with internal secretions it should not be simply a matter of thyroid or acromegaly, but it should come home as a daily thing in their lives that chronic or local infection was a symptom of defective internal secretions, and that those secretions could be elaborated in the body when there were youth, strength, and health by the application of a stimulant given in the proper quantities and at proper intervals and given always in the light of careful and systematic examination of the blood.

The discussion was then adjourned.

MEDICAL SOCIETY OF LONDON.

Discussion on Acute Intestinal Obstruction.

A MEETING of this society was held on March 14th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Dr. W. HALE WHITE opened a discussion on Acute Intestinal Obstruction by communicating a paper on the early diagnosis of the condition which is published at p. 791 of the present issue of THE LANCET.

Mr. A. E. BARKER confined his remarks to an outline of the principles of surgical treatment in intestinal obstruction and to the most important details. He emphasised the fact that the condition under discussion was made up of three preponderating factors: (1) mechanical or anatomical; (2) physical; and (3) vital. It was pointed out that the mechanical factors *per se* were not dangerous if promptly relieved, as could be learned by the results of operations for strangulated hernia at an early stage. The physical factors induced by strangulation were certain to come on sooner or later—i.e., congestion of the retained bowel, thrombosis, and effusion, and they became very serious if neglected. But in the local and general vital changes due to the action of the toxins stored up under pressure in the bowel above the point of arrest lay the greatest dangers to the patient, whether operated on or not. In an advanced case of obstruction therefore the quick evacuation of this stored-up putrid material must be provided for either by artificial anus or, as preferred by Mr. Barker, by resection of several feet of bowel above the constriction and anastomosis of the remaining parts. The reasoning in support of this course was only lightly touched on, having been already published in THE LANCET of May 30th (p. 1495) and June 6th (p. 1576), 1903 Illustrative cases were quoted, however, and some specimens were shown. A sketch of the chief details to be observed in a case of acute intestinal obstruction was given and some remarks were made upon after treatment and complications. The stomach should be emptied, by stomach-tube if necessary, and the mouth washed out with antiseptics, warm brandy-and-water administered by the mouth, and a saline solution injected per rectum. Chemical germicides were, in Mr. Barker's experience, best avoided but thorough asepsis should be employed. Local analgesia, excepting perhaps towards the end of an operation, was to be preferred to generalised anæsthesia.

The PRESIDENT alluded to a case resembling renal colic which was about to be operated on for intestinal obstruction and in which he prescribed warmth to the abdomen and rest and the patient duly recovered. The responsibility of the physician in such cases was very great. Some observers had referred to leucocytosis as being a characteristic of intestinal obstruction as well as of appendicitis. Urgency of symptoms was an indication of the amount of constriction rather than its position as taught by older authors.

Mr. C CARTER BRAINE was very interested in Mr. Barker's views on the use of local analgesia. He had often had an anxious time in the administration of general anæsthesia. It was a very good plan to wash out the stomach repeatedly, since there was a constant tendency to regurgitation of stercoraceous material.

Dr. J. VINCENT BELL (Rochester) referred to cases of obstruction by a volvulus and by bands of adhesion.

Mr. H. J. WARING referred to the diagnosis of true acute intestinal obstruction from hysteria. The resemblance was often very great, the character of the pulse being a valuable aid. He mentioned a case of hysteria which had been operated on by four eminent surgeons at different times for obstruction of the bowels. It was of importance to examine per rectum before diagnosing the obstruction or its cause.

Dr. HALE WHITE and Mr. BARKER replied.

PATHOLOGICAL SOCIETY OF LONDON.

Recent Experimental Work on Bacillary Dysentery.—Deep Chromatin Staining in Malaria.—An Unusual Anatomical Lesion.

A MEETING of this society was held on March 15th at the Royal Army Medical College, Victoria embankment, Lieutenant-Colonel R. H. FIRTH, R.A.M.C., being in the chair.

Lieutenant-Colonel FIRTH communicated notes on some Recent Experimental Work concerning Bacillary Dysentery, in which he explained that while there could be no doubt as to the existence of bacilli in the intestinal dejecta from cases of acute dysentery which were capable of differentiation from the common colon and enteric micro-organisms all the bacilli which had been described as being the specific cause of bacillary dysentery were probably not so. In the course of a detailed examination of a considerable number of these dysentery bacilli, derived from a variety of sources, it was possible to divide them into those which were pathogenic and those which were not. Pathogenicity had been determined in the rabbit and although both varieties presented morphological resemblances in common, the distinctive cultural features of the non-pathogenic group seemed to be an ability to split maltose, galactose, and mannite with the formation of acid but without production of gas, also to produce indol. These characteristics were wanting in the pathogenic varieties. The non-pathogenic forms were apparently the "pseudo-dysentery bacilli" of some authors but whether they represented degraded or transitional forms of the pathogenic type he was unable to say. As representative of the true bacilli of dysentery he mentioned the organisms associated with the names of Shiga, Vaillard, and Kruse. After demonstrating the cultural reactions of the two types he pointed out that from the point of view of their agglutination reactions the two groups presented marked differences; whereas the serum derived from animals immunised with one or other of the pathogenic varieties was capable of reacting upon the other members of the same group in high dilutions, it had little or no effect upon those of the non-pathogenic group; moreover, there was no concordant interaction between members of this latter group and sera resulting from immunisation with similar non-pathogenic strains. The same experiments had shown that in the rabbit, although a serum had developed marked agglutinating functions, it had no antitoxic action. While in rabbits no ill effects followed when the dysentery organisms or their toxins were administered either by the mouth or by direct injection into the intestinal tract, as exposed by a preliminary laparotomy, lesions characteristic of those found in human dysentery could be produced by subcutaneous inoculation. Examples of these were exhibited showing ulcerated and sloughing areas in the cæcum and large intestine; also sections of some of the affected parts in which the bacillus seemed to be affecting primarily the submucous layer of the bowel. The lesions could be caused not only by injections of living bacilli but also by cultures killed by heating to 60° C. for half an hour; these same effects followed inoculations with a sterile filtrate derived from a four-day-old broth culture and also with the filtrate obtained from a sterile autolysed maceration in water of bacilli which had been killed by chloroform. The existence of toxic broth filtrates had been denied by some, but provided care were taken to see that the broth in which the dysentery bacilli were grown was definitely alkaline no difficulty was experienced in obtaining a highly toxic filtrate. The dysentery bacilli and the toxic substances elaborated by, or contained in, their bodies appeared to have a selective affinity for the cæcum and large bowel, as it was remarkable that in all these cases of dysentery the blood and organs and mesenteric glands were sterile. Recognising the apparent elective affinity which the pathogenic strains had for certain parts of the intestinal tract when injected subcutaneously, and also the failure to bring about the same effects when the bacilli or their toxins were introduced directly into the alimentary canal, some interesting observations had been made as to the possibility of there being some toxin-fixing or neutralising substance in the epithelia of the intestinal tract of the rabbit. Emulsions in salt solution were made under antiseptic precautions of a virulent culture of the dysentery bacilli with tissues from various organs of a healthy rabbit, such as the spleen, liver, kidney, voluntary muscle, and the epithelium scraped from some ten inches of the cæcum and large bowel. After centrifugalisation five cubic centimetres of the clear liquid were injected into five rabbits, a sixth being taken for a control injection with an emulsion of the bacilli alone. The control died on the third day, the rabbits which had received the bacilli with emulsions of spleen, liver, kidney, and muscle died on the fourth day with characteristic lesions, while the animal inoculated with the mixture of bacilli and emulsified intestinal epithelia survived until the eighth day. In a second experiment the antitoxic influence of the intestinal epithelia was more marked, the animal surviving. Some facts had been established as to the viability of these dysentery organisms outside the body, indicating that, desiccated in soil or on rags, the bacilli could survive some 21 days, while from tap water kept at 22° C. they were recoverable up to 55 days and at 37° C. up to 28 days. If spread on ordinary bread these bacilli survived a week. The inquiry justified the conclusion that the dysentery bacilli were a specific group capable of producing definite lesions in the cæcum and large bowel of varying degrees of severity, such as catarrh, simple petechial patches, punctiform ulcers, large erosions, and even complete sloughing of large areas of the mucous membrane. In accordance with these lesions the clinical entities called dysentery produced by these pathogenic bacilli represented a group rather than a single class of cases and might range from the infective diarrhœas of infants and adults through the various degrees of ileo-colitis to the typical acute dysentery of camps and the tropics. There was still something to be done to explain the precise antecedents essential to infection, as, arguing from these experiments on the rabbit, it was difficult to explain the epidemiological facts by the orthodox channels of polluted drink and food only, without premising some condition which antecedently either inhibited or lessened the apparently normal defence against infection inherent in the intestinal mucous membrane.

Major W. B *LEISHMAN*, R A.M.C., read a communication on Deep Chromatin Staining in Malaria. After alluding to the great advance in knowledge of the structure and development of the parasites of malaria due to the specific colouration of the chromatin by the method of Romanowsky and its numerous modifications, Major Leishman proceeded to describe the effects of deep chromatin staining on the different varieties of malaria parasites, with special reference to the changes which this intense staining demonstrated in the red corpuscles infected by these parasites. By means of diagrams and stained blood films Schuffner's dots in the cells invaded by benign tertian parasites were demonstrated; it was pointed out that a very moderate grade of intensity of staining sufficed to show them and that their presence was constant and was diagnostic of this variety. In quartan malaria, on the other hand, he, in common with other observers, had failed to demonstrate any changes in the red cells by the most intense staining. As regards malignant tertian or tropical malaria, the work of Stephens and Christophers, of Maurer, and of Argutinsky was described and contrasted and stained films were shown demonstrating, first, the dots in the red cells infected by young malignant schizonts; and secondly, the deeply stained capsules surrounding the mature gametes or crescents, as described and figured by Maurer. In view of the apparently contradictory results obtained by Maurer and Argutinsky and of his own failure, except in a few instances, to demonstrate Maurer's dots and capsules, Major Leishman suggested that these discrepancies might be due to there being more than one variety of tropical or crescent malaria and that the differentiation of this fever into malignant tertian and quotidian, although largely abandoned, except by the Italian and American schools, might prove to be correct. The existence of two or more distinct species of malignant parasites would account for the difference in the results obtained, and he suggested that the systematic investigation of these malignant parasites by means of deep Romanowsky staining should be under taken with a view to settle this disputed point. In showing some sketches of the capsulated crescents Major Leishman drew attention to some forms which appeared to him interesting as indicating the probable mode of development of the characteristic crescent from a circular intracorpuscular parasite somewhat similar to the gametes of benign tertian and quartan malaria. Specimens were also exhibited of sections of brain from a case of malarial coma to show the effects of Major Leishman's stain as applied to sections.

Dr. T. J. HORDER showed a pathological specimen in which the chief point of interest was a Massive Form of Consolidation of the Left Lung associated with a Small Aneurysm of the Descending Thoracic Aorta. The sac of the aneurysm, of about the size of a large pea, had ulcerated through the wall of the left bronchus, which was found to be much dilated and filled by adherent, laminated blood clot. The surface of the bronchus was also ulcerated. The lung was uniformly affected, the chief changes being great increase in new fibrous tissue and the filling of the alveoli by large endothelial cells and plasma cells. There was no collapse or any broncho pneumonia. The pleura was much thickened. Microscopic examination of the blood clot showed organisms present; a few could also be demonstrated in the lung. Although the vagus nerve was much compressed no degeneration could be demonstrated in its trunk below the level of the pressure. The patient from whom the specimen was obtained had been suddenly seized with intense dyspnœa, cough, and pain in the chest, but lived eight weeks after this, the chief clinical features being rapidly developing loss of function of the left lung, until this was complete, and quotidian intermittent fever. There was a history of syphilis and examination of the aorta after death showed a condition of syphilitic aortitis. In addition to the naked-eye specimen, lantern slides and microscopical preparations illustrating the case were exhibited.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on March 10th, Sir ANDERSON CRITCHETT, the Vice President, being in the chair.

Mr. J. R. LUNN showed an elderly man with Compression of the Retinal Veins by Thickened Arteries in One Eye, the vessels in the other eye showing also some degeneration. A large area above the macular region was occupied by a hæmorrhage. Owing to the serious view of such cases taken by Mr. R. M. Gunn he proposed to bleed the patient, while Mr. E Nettleship had suggested purging him as well.—Mr. GUNN said that although he looked upon such cases as grave, yet that as in this case there was no albuminuria he thought it rather a favourable one.

Dr. H B. GRIMSDALE exhibited a man, aged 24 years, who had suffered from Gonorrhœal Ophthalmia a year before, resulting in a dense leucoma in one eye. When light was allowed to shine on to the sound eye the pupil contracted, while the other eye rotated distinctly upwards, and when light was withdrawn the reverse took place, the affected eye rotating downwards. This condition had been previously noticed after head injuries but had not before been described as occurring in such a case as the present one.

Dr H. L. EASON showed a case of what he took to be a Persistent Hyaloid Artery. The right eye had defective vision and nystagmus. The vessels were seen emerging from the lower border of the disc, one branch running forwards [illegible]

[illegible] persistent hyaloid artery?—Mr. E. TREACHER COLLINS saw no reason for doubting that it was really a persistent hyaloid artery and that, in addition, there had been atypical development of the vitreous.

Dr EASON also showed a patient with Albuminuric Retinitis who, three years before, had acute nephritis, anasarca, and detachment of both retinæ. His general condition had greatly improved and the detachment in both eyes had subsided.

Mr. CLAUD A. WORTH showed a member of a family in whom Congenital Dislocation of the Lens was present in [illegible] 24 years before Mr. A. Stanford Morton had described the family in a paper in the Royal London Ophthalmic Hospital Reports and since then two more members had been born, both with the same condition —Sir ANDERSON CRITCHETT thought that such a series of cases was most important as bearing on the subject of heredity.—Mr. NETTLESHIP thought that possibly a slight luxation of the lens in young children might account for the high degrees of myopia which were occasionally seen and which did not get worse as time went on.

Dr. A. H. THOMPSON showed a girl, aged 10 years, who had a Congenital Coloboma of the Iris downwards in one eye. Near the periphery of the fundus and well below the macula were a white patch with indefinite edges and a band of healthy choroid crossing it. In view of the condition of the iris Dr. Thompson took it for a coloboma, otherwise he would have been inclined to regard it as a patch of choroidal atrophy. The vision was $\frac{6}{18}$ and the left eye was normal.

Mr. N. BISHOP HARMAN showed a girl, aged five years, with the following Abnormalities: the anterior fontanelle was not closed; a coloboma of each upper lid; a coloboma of the iris and choroid on one side; two dermoids of the globe on the right side; very tortuous retinal vessels; an imperfect mouth; a depression over the sacrum representing the tail (fovea sacralis); and two ears on the right side and four on the left. The child was unable to walk or to say more than a few words.

Dr. A. H. BENNETT showed a girl, aged nine years, who, when first seen in October, 1903, had Keratitis Punctata in the right eye; she was not again seen until she attended as an out-patient under the care of Mr. Claud Worth at the West Ham Hospital on Feb. 18th last. The right eye had been red for a month and the sight had failed without pain. With this eye she could only see hand movements; the vision of the left was $\frac{6}{6}$ The right eye was inflamed with gross, oily-looking patches of keratitis punctata. The iris was yellowish and the pupil was occluded. There were five tuberculous-looking masses growing near the angle of the anterior chamber, varying from the size of a shrivelled barley corn to that of a No. 6 shot. These appeared to be fluffy as though covered with exudation. The eyeball was not tender and there was no fundus reflex. The left eye was normal except for slight ciliary redness. Atropin was applied and hydrargyrum cum cretâ and syrupus ferri phosphatis compositus were given internally. Two weeks later the exudate had mostly disappeared and small blood-vessels were seen on the surfaces of the growths. The left eye when exhibited showed typical pyramidal keratitis punctata; the vision remained the same; the lungs were healthy but the cervical glands were enlarged. The family history disclosed nothing either specific or tuberculous.

Mr. GUNN showed a drawing of an Eye with Maldevelopment of the Suspensory Ligament. The patient complained of symptoms suggestive of a refractive error, but after the use of atropin the upper edge of the lens, instead of being convex, was, roughly speaking, horizontal. At two or three places some fibres of the suspensory ligament came down and were attached to it, thus giving rise to elevations along this edge. There was also a coloboma of the lens downwards.

CLINICAL SOCIETY OF LONDON.

A Case of Polycythæmia with Enlarged Spleen.—Intracranial Resection of the Second Division of the Fifth Nerve for Neuralgia.—Foreign Body impacted in the Left Bronchus.

A MEETING of this society was held on March 11th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. F. PARKES WEBER and Mr. J. H. WATSON communicated a paper on a case of Chronic Polycythæmia with Enlarged Spleen and probably Disease of the Bone Marrow. The patient was a man, aged 58 years, a native of Holland, who had noticed for the last six or seven years a variable amount of cyanosis in the face and extremities. In 1903 he fractured some ribs and afterwards commenced to have delusions of persecution. The peculiar symptom-complex of chronic cyanosis with splenomegaly and polycythæmia was observed at the German Hospital in the latter part of 1903. At Colney Hatch Asylum, to which he was removed, he remained bodily and mentally feeble and during an attack of greatly increased cyanosis died suddenly on Feb. 4th, 1904. Apart from the mental symptoms the chief features of the case were: chronic cyanosis, not to be accounted for by the condition of the heart and lungs; chronic enlargement of the spleen, though the splenic substance appeared little altered at the necropsy; polycythæmia, the blood containing about double the normal amount of red corpuscles and the hæmoglobin value being about 170 per cent. of the normal; increased arterial blood pressure; extreme distension of the small veins with blood, well seen during life in the retina by ophthalmoscopic examination and after death in the viscera; relative dryness of the skin and tissues in spite of there being an absolute plethora of blood in the blood-vessels; urine diminished in amount, highly coloured, and containing a little albumin; frequent digestive disturbance and chronic constipation; tendency to vertigo and to feeling of prostration; and changes discovered after death in the bone marrow of the shafts of the long bones, the red transformation and disappearance of fat indicating doubtless increased activity in the production of blood corpuscles. Dr. Weber and Mr. Watson thought that injuries to bones might increase the polycythæmia (1) by exciting the bone marrow to increased activity, and (2) by rendering rest indoors necessary and thus diminishing the destruction of red blood corpuscles. In the treatment of cases drugs (such as iron compounds) and foods supposed to increase the erythrocyte-forming functions of the bone marrow ought as far as possible to be avoided. A permanent increase of the osmotic tension of the blood would probably account for the main symptoms of the case, but the presence of such increased osmotic tension could only be confirmed or negatived by the investigation of similar cases. By experiments in Professor J. McFadyean's laboratory with fresh horse's blood, in which coagulation had been prevented by the addition of potassium citrate, Dr. Weber and Mr. Watson, using glass thermometer tubing, had succeeded in proving that, other conditions being similar, increase in the proportion of corpuscles to plasma decidedly raised the "viscosity" of blood.—Dr. NORMAN DALTON inquired if any of the ductless glands in the body were similarly enlarged.—Dr. HERBERT S. FRENCH remarked that if the disease was due to an excessive activity of the bone marrow he would have thought that the oxidation of the tissues would have been rendered thereby easier, whereas, on the contrary, cyanosis was one of the most prominent features. This seemed to suggest that the fault lay in the tissues themselves. He thought that experiments upon the comparative tensions of the carbonic acid and oxygen in the expired air in such a case would be valuable.—Mr. LEONARD S. DUDGEON asked if the blood from the small vessels had been examined as well as that from the tissues. He referred to the condition of the bone marrow, which was of a red colour, in a case of congenital heart disease accompanied by cyanosis which he had examined at the East London Hospital for Children.—Dr. W. PASTEUR asked if any thrombosis were present in Dr. Weber's case, as he had met with this condition in two cases of extreme plethora, both of whom died from pulmonary thrombosis at the age of 15 years.—Dr. J. W. RUSSELL (Birmingham) referred to a similar case which he had seen where the spleen was considerably enlarged before any cyanosis appeared. He was also struck with the extreme degree of asthenia present.—The PRESIDENT inquired whether the arteries in the retina were enlarged as well as the veins.—Dr. WEBER, in replying, said that the spleen in these cases might also be regarded as a manometer of the capillary circulation.

Mr. JONATHAN HUTCHINSON, jun., read notes of a case in which he had performed Intracranial Resection of the Second Division of the Fifth Nerve for Epileptiform Neuralgia. The patient had remained free from pain at the end of a year after the operation. The method adopted was that of trephining the temporal fossa, after which the trunk of the superior maxillary division of the fifth nerve was exposed and about half an inch was resected.—Mr. STANLEY BOYD mentioned the case of a woman, aged 69 years, in whom he had performed a somewhat similar operation for intractable neuralgia. In this case some recurrence of the pain took place after the end of the year, though to a much slighter extent than before the operation.

Dr. W. PASTEUR and Mr. T. H. KELLOCK communicated a case of Foreign Body impacted in the Left Bronchus. The foreign body, which was a glass stopper, was removed by operation. An account of the case will be found at p. 795 of our present issue.—The PRESIDENT referred to a case in which pulmonary symptoms were present resembling those of tuberculosis, insomuch that the patient was sent on a sea voyage. One day, however, he expectorated a little blood and a piece of broken tooth, after which the chest trouble which had persisted for some months, disappeared.—Mr. **GEORGE EASTES** remarked upon the value of inversion in these cases, especially when the foreign body was almost on the point of coming up but was sucked back again by inspiration.—Mr. **G. H. MAKINS** said that glass objects sometimes threw definite shadows on the screen He recalled a case of great dyspnœa due to a suspected foreign body in which the cause of death was found to be obstruction due to a caseating bronchial gland —Mr. **HUTCHINSON**, jun., remarked that the glass stopper, though to all appearances clean, was probably virulently septic, hence the formation of pus in the present case. He agreed that the flexible silver-wire loop often succeeded in extracting foreign bodies when all other means had failed.—Dr. **PASTEUR** and Mr. **KELLOCK** replied.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—The Site of Impregnation.—Abdominal Hysterectomy.

A MEETING of this society was held on March 2nd, Dr. **EDWARD MALINS**, the President, being in the chair.

Dr. **M. HANDFIELD-JONES** showed two specimens of Unruptured Tubal Gestation, both at about the seventh week. In one case death had occurred owing to severe hæmorrhage which had poured out from the open end of the tube. In the other cases only a couple of drachms of blood had escaped into the peritoneal cavity. In both cases much blood clot was found in the distended tube surrounding the ovum.

Mr. **HARRISON CRIPPS** and Dr. **HERBERT WILLIAMSON** described two cases involving the question of the Site of Impregnation. In the first case, after complete removal of the right ovary gestation subsequently occurred in the right tube. There were two possible explanations of this phenomenon—namely, (1) the presence of an accessory ovary on the right side; and (2) external migration of the ovum. These two possibilities were discussed in some detail and the conclusion arrived at was that external migration of the ovum was the more probable. Two similar cases recorded in the literature were quoted. In the second case a patient became pregnant after both Fallopian tubes had been ligatured; to prevent subsequent conception the abdomen was reopened and a portion of each tube was excised In spite of this the patient again became pregnant. Similar cases from the literature were quoted and the manner in which the ovum traversed the distended tube was discussed The bearing of these two cases upon the etiology of tubal gestation was briefly indicated.—Mr. **ALBAN H. G. DORAN** observed that in respect to Case 1 he considered that the existence of ovarian tissue on the same side as the Fallopian tube fully explained the subsequent pregnancy. External migration seemed to him less probable. In regard to Case 2 it was not necessary to assume that the continuity of the entire canal of the partially excised tube must be restored before the tube could resume its functions. These two opinions were supported by the published reports of authentic cases of pregnancy after double ovariotomy. Mr. Doran removed a cyst of the right ovary 14 years after the left had been amputated for cystic disease by Dr. Robert Barnes and noted complete atrophy of the pedicle on the left side. Yet the patient bore a child to term two years later. [illegible] right tube and a trace of ovarian tissue [illegible] to allow of impregnation [illegible] possible. Stansbury-Sutton, [illegible]orris, and Anderson Robertson reported cases where both ovaries and tubes were amputated for cystic or inflammatory disease, yet the patients bore children afterwards. The stump of one tube had become patent (ligatures seldom closed mucous canals securely) and thus an ovum was conveyed from ovarian tissue to the uterine cavity. It followed that in partial excision of the tube for the induction of sterility restored patency of the uterine portion was sufficient to defeat the operator's aims.—Dr. **WILLIAMSON** said that though he appreciated the justice of Mr. Doran's criticism in this particular case he was still in favour of external migration of the ovum —Dr. **G. E HERMAN** said that there was abundant evidence that the ovum might traverse the peritoneum from one ovary to the opposite tube. There was also some evidence that an ovum might traverse the uterus and get from one tube into the other. Knowing that ligature of the tube did not insure sterility he had endeavoured to sterilise patients after Cæsarean section by removing the tubes altogether, tying the stumps close to the uterine cornu, and so far he had not heard of any patient so treated becoming pregnant.—The **PRESIDENT**, Dr. **A. L GALABIN**, Dr. **ROBERT BOXALL**, and Dr. **C. J. CULLINGWORTH** also took part in the discussion.

Dr. **FLORENCE N. BOYD** described two cases of Abdominal Hysterectomy for Fibroids complicated by Pregnancy. The first patient was 42 years of age and had a hard fibroid in Douglas's pouch, almost filling the pelvis. The tumour tended to fall back and at the end of pregnancy was found to be non-replaceable and very tender; it also obstructed the entry of the presenting vertex into the brim. A Porro-Cæsarean section was performed. After delivery of a living child the uterus and several fibroids were removed by supravaginal amputation. The patient died on the third day with great acceleration of pulse and marked distension of the abdomen. The necropsy showed local peritonitis at the site of adhesion, to which a coil of bowel was attached; cultures from the blood and peritoneal fluid proved sterile. The second patient was 41 years of age, her uterus was removed entire in the fifth month of pregnancy, and she made a good recovery.—Mr. **ALBAN DORAN** said that in his opinion hysterectomy early in pregnancy was the safest treatment when the fibroid sprang from the posterior part of the inferior uterine segment —Dr. **HERBERT R. SPENCER** showed a specimen of Degenerative Fibro-myoma, weighing over 17 pounds, enucleated from the broad ligament nine hours before delivery at term. The child was born dead but seemed quite fresh. It was 21 inches long and weighed 6 pounds 2 ounces The mother, who was 41 years of age and had had four children previously, made a good recovery. Dr. Spencer said that although he had seen a considerable number of pregnancies complicated with uterine fibroids this was the only case but one in which he had found it necessary to operate during pregnancy. Tumours which encroached on the pelvis in the early months were often drawn up at the end of pregnancy or in labour. He was of opinion that operations in the early months and mutilating operations were by far too frequently performed in cases of fibroids complicating pregnancy. The specimen showed that even at full time a very large tumour might be successfully removed by the operation of myomectomy. He had no doubt that both the cases shown by Mrs. Boyd required operation but thought that in the second case it would have been better to wait and to see whether the pregnancy could not be allowed to continue until the child was viable or even developed to term. Whether the uterus should have been removed in that case was, perhaps, doubtful, but in the case of a pedunculated tumour, such as in one of Mr. Doran's cases, he thought the conservative operation of myomectomy was preferable —Dr. **AMAND J M ROUTH** spoke strongly against operative interference in the early months of pregnancy unless very urgent symptoms were present, especially as two lives were involved, and all interference must be surgical, myomectomy or hysterectomy, the induction of abortion being unjustifiable for obstructing fibroids.—Dr. **CULLINGWORTH** and Dr. **A. H. N. LEWERS** also took part in the discussion.

ULSTER MEDICAL SOCIETY.

The Present Position of Cardiac Therapeutics.—Exhibition of Specimen.

A MEETING of this society was held in the Medical Institute, Belfast, on March 3rd, Dr. **JOHN CAMPBELL**, the President, being in the chair.

Professor **J. A. LINDSAY** opened a discussion upon the Present Position of Cardiac Therapeutics. He said that he would deal with the subject from three points of view: (1) the treatment of functional affections of the heart; (2) the treatment of valvular lesions during the stage of complete compensation; and (3) the treatment of valvular affections during the stage of failing compensation. As to functional affections, treatment must have regard to cause, whether nervous, heredity, exhaustion from work, worry or indulgence, too free use of tea, coffee, tobacco, or alcohol, or emotional stress. The regulation of diet and habits was more important than drugs. Hydropathy had and if pursued energetically it was sometimes disastrous. Change to upland air was useful. The best drugs were probably strychnine or arsenic. The former should not be given if there was much irritability. Anæmia called for iron. The bromides should be used sparingly as in general a tonic was preferable to a sedative regimen. He did not find digitalis or strophanthus valuable in functional affections. As regarded the treatment of valvular affections during the stage of complete compensation, he deprecated any active therapeutics. The patient's habits and occupation required some supervision. His amusements might call for some restriction. The propriety of sanctioning cycling in these cases was doubtful. Tonics might be useful but the special cardiac remedies should be withheld. These patients should be dissuaded, when practicable, from selecting the career of a soldier, sailor, engineer, or politician. The medical profession was not very suitable for persons the subjects of organic valvular disease but some of the special branches might be selected. Law and divinity were permissible careers. Women the subjects of mitral stenosis or aortic regurgitation should be advised against the risks of matrimony. As regards the treatment of valvular affections during the stage of failing compensation, the first question was the due apportionment of rest and exercise. He believed that rest should in all cases have priority when there were active symptoms. Patients sometimes fancied that they could "walk off their shortness of breath," but it was a serious question whether this did not usually mean a blunting of sensibility rather than the rallying of the heart to the strain thrown upon it. Rest could no doubt be abused but it should come first. When some improvement had been obtained the question of graduated exercises or mitigated labour would arise. The diet of these cases should be fairly dry and mainly proteid in character. A sloppy diet or a diet rich in carbohydrate material was in most cases injurious. If much gastric catarrh was present or if the urine was scanty and concentrated solid food might require to be forbidden temporarily. With regard to drugs, he held that there was one sovereign remedy for failing compensation in valvular disease—viz., digitalis—and he regarded all other remedies as of quite minor importance. He thought that they would be more profitably employed in studying the action of digitalis than in trying to find substitutes for it. He advised the use of the remedy by itself and preferably in the form of the powdered leaf. Mercury and iron were the most important drugs to be given in combination with digitalis but he preferred to give the latter drug as a rule without accompaniment, using mercury, iron, or other combination from time to time as the patient's condition and symptoms might require. It was a question whether the "intensive" plan of giving digitalis—viz., in doses of one and a half grains of the powdered leaf every two hours for two or three days—with the view of bringing the patient rapidly under the influence of the drug was a good one. Douglas Powell thought that this plan led to "premature arterial contraction and cumulative effects." It must be remembered that digitalis was a very slow-acting drug. It was useless where an immediate effect was required. He was in the habit of advising occasional intermissions in the use of the drug in the case of a prolonged course of digitalis and he had never seen a well-marked case of cumulative effects. Many patients could take the drug continuously for long periods without ill effects but as a general rule occasional intermissions were desirable. If gastric symptoms proved troublesome digitalis should be suspended for a time and then tried again. In most cases of the continuous exhibition of digitalis an occasional mercurial purge was requisite. In some cases attended by much cyanosis and distension of the right heart the abstraction of a few ounces of blood by leeching was an important adjuvant to the action of digitalis. In senile patients iodide of potassium was sometimes an indispensable addendum to a course of digitalis. Digitalis was most valuable in mitral regurgitation and in aortic regurgitation with secondary mitral reflux. He did not share the fears sometimes expressed regarding the safety and value of digitalis in aortic regurgitation. His experience was that the remedy was of great service in this lesion. In mitral stenosis he had found digitalis disappointing and sometimes injurious, which was not surprising when they reflected that increased force of the systole of the right ventricle might aggravate the patient's sufferings in this lesion. He had been much disappointed with the effects of strophanthus but in some cases of mitral stenosis it might prove more valuable than digitalis. Strychnine was a most valuable remedy in failing compensation but it must be given hypodermically and with a free hand. The usual tonic doses given by the mouth were almost useless. It shone most conspicuously in emergencies—i.e., in circumstances where digitalis was of least service. He had seen some benefit from caffeine. He thought it a waste of time to give convallaria, spartein, cactein, or casca. In the treatment of cardiac insomnia he thought that the moderate use of morphine by hypodermic administration to be much the most important remedy. He could not endorse the high place assigned by some observers to paraldehyde in this condition. He had found it a most uncertain remedy but sometimes it acted well. The question of the use of nitro-glycerine in failing compensation was a most important and much controverted one. He thought that the use of this drug in ordinary cases was bad practice. Its value in anginoid states was, of course, undoubted. The treatment of valvular disease by graduated exercises and by baths was an important question of which much had been heard in recent years. He had paid one visit to Nauheim but could not speak from any considerable experience of the Nauheim methods. He thought that the special form of exercise in cardiac cases was less important than the determination of the prior question whether any given case was one for exercise or for rest. It was a question whether "resistance" exercises possessed any decided advantage over properly regulated exercise in the fresh air upon the flat or on certain inclines, according to the special indications of the individual case. In the successful management of cardiac cases much depended on the docility of the patient, the state of his tissues, and the *savoir faire* of the profession.

In the discussion which followed the following members took part: Sir William Whitla, Dr. J. McCaw, Dr. R. W. Leslie, Dr. A. Dempsey, Dr. H. L. McKisack, Dr. J. S. Morrow, and Dr. D. P. Gaussen.

Professor Lindsay briefly replied.

Dr. Dempsey showed a Fibro-myoma of the Uterus successfully removed.

West London Medico-Chirurgical Society.—A meeting of this society was held on March 4th, Dr. Seymour Taylor, the President, being in the chair.—Mr. G. A. Garry Simpson read a paper entitled "Adenoid Growths, When and How to Operate." He recommended breathing exercises for those patients who had a temporary engorgement of some already existing lymphoid tissue due mainly to an attack of acute rhinitis; such cases, however, should be watched for any further developments. Frequently recurring attacks of deafness were strong indications for operative interference and a chronic otitis media would clear up much more rapidly if any existing adenoid growths were removed. Deaf patients with retracted drum membranes were benefited by an operation, provided that the mischief had not existed for too long a period. The nose ought to be examined in every case, because if any obstruction was overlooked the operation would fail to restore nasal respiration. An operation ought to be performed if a child was a habitual mouth-breather. Mr. Simpson had never found that patients suffering from enuresis were benefited by the operation. He preferred to operate with the patient lying on his right side near the edge of the table, with the legs slightly drawn up. The head, which rested on a low pillow, was thus made dependent and no blood or fragments of the growths could enter the larynx. He preferred chloroform for children under ten years of age and nitrous oxide gas and ether for older patients.—Dr. E. Furniss Potter said that he believed the carrying out of breathing exercises as described to be quite inapplicable in private practice and considered that much less worry as well as a more certain result were likely to accrue from the radical operation for removal of the adenoids. Thoroughness of removal was more important than rapidity of operation and thoroughness could not be assured in the short time allowed by "gas only." Nitrous oxide gas followed by ether he considered to be much more satisfactory and if properly administered there need be no anxiety on account of the anæsthetic. With chloroform there was a much larger proportion of cases which gave rise to this anxiety. On the whole the forceps was a more certain and trustworthy instrument than the Gottstein curette although its use entailed a greater expenditure of time.—Mr. Stephen Paget maintained that the risk of increased loss of blood was a serious argument against performing the operation very deliberately and that there was no positive evidence of the necessity for a protracted operation.—Dr. G. E. Shuttleworth said that breathing exercises were of value in counteracting the habit of mouth-breathing which frequently persisted after adenoid operations, as well as remedial in the milder cases which were not submitted to operation. Such was his experience in the case of feeble-minded children, with whom he was specially conversant and for whom he prescribed these exercises in the upright position as part of their daily school drill.—Dr. J. B. Ball, the President, and Mr. A. B. Kingsford also took part in the discussion.—Mr. Paget read a paper on the Uses of Paraffin in Plastic Surgery. He had employed this method in more than 60 cases of sunken nose and in several cases of prolapse of the bowel. In the treatment of sunken nose it was necessary to avoid attempting to do too much. Everything depended on the state of the skin. If the skin were fairly free, soft, healthy, not scarred, and not adherent the surgeon might anticipate doing a great deal of good and the risk was that he might do harm by trying to do too much good. In cases of prolapse of the bowel a great deal of good could also be done. In operating on the nose the presence of ozæna or of perforation of the septum did not hinder a successful result, provided only that the skin were healthy, free, and fairly abundant.—Dr. Ball said that he had operated in 14 cases of depressed bridge of the nose by this method with satisfactory results. He agreed with Mr. Paget as to the necessity for not injecting too much paraffin. It was better to be under the mark than over it.

Otological Society of the United Kingdom.—A meeting of this society was held at 11, Chandos-street, London, W., on March 7th, Dr. Thomas Barr, the President, [illegible] He opened the resumed dis- [illegible] on the Etiology and Treat- [illegible] In his opinion vertigo was not to be relied on as an indication for operation, nor did erosion of the inner walls of the tympanum and antrum always imply fistular communication between those cavities and the labyrinth. Patients often recovered from these conditions after the complete post-aural operation and without exploration of the labyrinth. On these grounds and because the mastoid operation itself was a long and tiring one he advocated operating in two stages. He thought that the posterior limb of the external semicircular canal was a better way of approaching the labyrinth than either the anterior limb of that canal or the inner wall of the tympanum on account of the proximity of these structures to the facial nerve and bulb of the jugular vein respectively.—Mr. A. L. Whitehead gave an analysis of 691 cases of complicated middle-ear suppuration dealt with by himself and colleagues at the Leeds General Infirmary. There were 27 cases of suppuration of the labyrinth. Of these 14 had facial palsy, five had vertigo, and 11 had no special symptoms; 11 died—six from cerebellar abscess, three from meningitis, and two from marasmus. He cautioned members against too early attempts to remove large sequestra.—Dr. Urban Pritchard supported the views expressed by Mr. Cheatle and suggested the use of a 1 per cent. solution of nitric acid, as practised by himself for many years, for the decalcification of sequestra.—Dr. J. Dundas Grant discussed the difficulty of exploring supposed fistulæ in the labyrinthine walls without producing the very disease the existence of which was feared. Latent labyrinthitis was very difficult to diagnose.—Mr. C. H. Fagge said that in his opinion the posterior limb of the external semicircular canal was the best route for the exploration of the labyrinth.—Mr. Richard Lake referred to the frequent causation of deaf-mutism by necrosis of the labyrinth, especially in scarlet fever.—The President spoke of the intimate relations of the cerebellar fossa and the labyrinth and the consequent frequency of intracranial lesions in labyrinthine suppurations. He also referred to the fallacies of Weber's test for nerve deafness, instancing a case in which the sound of the tuning fork was referred exclusively to the affected ear, although it was proved by necropsy (death occurred from meningitis) that the labyrinth had been destroyed.—Dr. Dundas Grant reported a case of Thrombo-phlebitis of the Sigmoid Sinus in which recovery took place after removal of the suppurating clot from the sinus and without ligation of the internal jugular vein.—Mr. Lake showed four patients with drawings of the Membrana Tympani. One case had herpetic vesicles on the lip, the concha, and the membrana tympani. The other three had aural pain and papules on the membrana tympani which were "nearly allied to, if not actually, herpes."—Dr. E. Furniss Potter showed a patient with signs of Hereditary Syphilis in whom appreciable improvement of hearing had occurred apparently as the result of treatment by subcutaneous injections of pilocarpine.—Mr. Cheatle and Dr. Pritchard expressed the view that pilocarpine was of less value than repeated blistering behind the ear even in cases of labyrinthine deafness due to hereditary syphilis.—Dr. Peter McBride and Mr. Lake maintained that pilocarpine was useful in labyrinthine deafness.—Dr. Dundas Grant said that pilocarpine was valuable where there was evidence of hyperæmia of the labyrinth but was strongly contra-indicated where the evidence pointed to anæmia.—Various specimens were shown by Dr. Herbert Tilley, Mr. Hugh E Jones, Dr. L. H. Pegler, Mr. Cheatle, and Dr. W. Jobson Horne.—It was announced that the next meeting of the society would be held at Glasgow.

British Gynæcological Society.—A meeting of this society was held on March 10th, Dr. John W. Taylor, the President, being in the chair.—Dr. H. Macnaughton Jones exhibited for Dr. T. Gelston Atkins of Cork specimens from two cases treated by Hystero-salpingo-oöphorectomy. The first case was one of large bilateral ovarian abscesses and the patient made a good recovery. The other case was one of bilateral papilloma of the ovaries with cancer of the cervix and the woman made a good recovery from the operation but died from tachycardia on the ninth day.—Other specimens were shown by Dr. William Duncan, Dr. J. Inglis Parsons, and Dr. Bedford Fenwick.—Dr. Dudley W. Buxton read a paper on the Vernon-Harcourt [illegible] observers on its effects upon the isolated mammalian heart and upon the nervous and vaso-motor systems (Sherrington, Sowton, Waller, Rudolph, and Embley). With low percent- [illegible] s had described [illegible] ur was found to [illegible] narcosis, while an even lower percentage maintained anæsthesia. After a careful comparison of "incomplete" or "irregular" and "light" anæsthesia, Dr. Dudley Buxton showed that most of the perils of chloroform arose from incomplete and irregular anæsthesia. He exhibited the inhaler devised by Mr. A. Vernon-Harcourt to supply a vapour of 2 per cent. or any lower degree that might be desired; by using it the after-effects were lessened while the dangers were minimised. The results obtained by its intelligent employment had proved most satisfactory.—Mr. A. W. Mayo Robson said that from his experience of the Vernon-Harcourt inhaler in a large number of serious cases he could confirm all that Dr. Dudley Buxton had said in its praise; it would, in his opinion, completely revolutionise the giving of chloroform.—Dr. Macnaughton Jones, also speaking from experience, said that the induction of anæsthesia with it did not take more time than with the Junker apparatus nor was it ever necessary to continue the full 2 per cent. vapour to maintain anæsthesia.—Dr. R. T. Bakewell eulogised the inhaler, especially for children, but explained that on account of the dislike that children had to any form of mask it was convenient to commence the anæsthesia with a few drops of chloroform on lint.—Mr. Vernon Harcourt said that he had found it better to substitute metal valves for the celluloid ones which he employed at first, as the latter were affected by the vapour of chloroform and lost their shape; moreover, being transparent their action could not be so satisfactorily observed as with metal valves. He inquired whether some form of stand to keep the instrument upright and the interposition of about 20 inches of tubing between it and the face-piece might not be beneficial in saving the administrator fatigue in long operations or in obstetric cases.—Dr. Dudley Buxton said that to one accustomed to the instrument the fatigue was not great even in long operations but that such an addition might prove useful in some instances.

Harveian Society of London.—A meeting of this society was held on March 10th, Dr. C. Theodore Williams, the President, being in the chair.—Dr. S. Vere Pearson read a paper on the Diagnosis of Pulmonary Tuberculosis in Infants and Young Children. The diagnosis of intrathoracic tuberculosis was considered under four heads. 1. Broncho-tracheal gland affection. The differentiation and classical symptoms were described. The differentiation from a persistent cough following whooping-cough was dealt with; it depended upon the exclusion of the two common causes of such persistent cough—namely, adenoids and habit combined with a tendency to repeated catarrhal attacks. If these were appropriately treated the cough usually soon disappeared unless tuberculous glands were present within the chest. 2. Miliary tuberculosis of the lungs. The diagnosis of this form depended upon a study of the general features, the history and course of the case, not upon any special local signs. An insidious and progressive wasting without adequate cause should arouse suspicion. The state of the skin, especially the presence in it of small hæmorrhages or of subcutaneous tubercles, the condition of the hair, irregular pyrexia, quiet demeanour, enlarged spleen, and the variety of anæmia present were important. The wasting had to be distinguished from simple marasmus and that due to septic infection, &c. 3. Tuberculous broncho-pneumonia. Certain peculiarities of this type were described and its differentiation from the simple form with its complications and from localised empyema, purulent pericarditis, and abscess of the lung was reviewed. 4. Rarer types of pulmonary tuberculosis. The varieties, the times of occurrence, and the nature of these types were dealt with briefly.—Mr. E. Laming Evans read a paper on the Treatment of Congenital Club-foot in Early Infancy and showed a number of cases. He advocated manipulation immediately after birth and early recourse to tenotomy of the tibials (anterior and posterior) and flexor longus digitorum for the cure of the varus, followed then by tenotomy of the tendo Achillis to overcome the equinus, with prolonged after-treatment in some apparatus and constant observation by the surgeon.—Mr. Noble Smith congratulated Mr. Evans upon his firm support of the principle of maintaining the fixation of the heel until the inversion of the foot had been entirely overcome. Until the great toe was brought into or beyond a straight line with the inner border of the patella the inversion could not be considered completely corrected. He supported early treatment and reverted to the difficulty of treating neglected cases. He strongly deprecated extensive operation and everything which tended to destroy the natural movement of the foot. Lately he had practised Lorenz's method which differed from the former forced manipulation by the persistency of the surgeon's efforts at the time of operation. He showed some casts and photographs illustrating excellent results obtained by the improved method of treatment.—Mr. J. Jackson Clarke agreed with Mr. Evans's method of treatment which he thought was now followed at all the orthopædic hospitals in London. There were a few exceptional cases in which other methods were required in order to obtain a perfect result. That of manipulation and fixation in plaster of Paris as practised by Lorenz was, in Mr. Clarke's experience, the most valuable. It should not be done until the child was able to walk. Preparatory cleansing of the skin should always be undertaken and sterility aimed at in case of rupture of the skin occuring during the manipulation. Such wounds in these circumstances gave no trouble and healed well under dry dressing.

Edinburgh Obstetrical Society.—A meeting of this society was held on March 9th, Professor A. R. Simpson, Vice-President, being in the chair.—Professor Simpson referred to the great loss the society had sustained through the death of Dr. R. Milne Murray. It was more than a year since pneumonia laid him low and deprived the society of his bright and always stimulating presence. He had recovered from the dangerously acute attack and was battling bravely with the after-consequences, so that when they heard of his working at a text-book they hoped that he was on his way to a full recovery. The surgical intervention that might have hastened his cure failed of its desired effect and his brilliant career came to an untimely close. He began the study of medicine with a singularly clear and well-trained mind disciplined first by his father at Fettercairn and afterwards in the University of St. Andrews, where he took the M.A. degree. He early showed himself at home in chemistry and physics and he became an acknowledged master in electricity. During his medical course he showed special interest in midwifery and gained a medal in that class. After graduation he devoted himself specially to obstetrics and gynæcology. He was a born lecturer and when he opened classes of his own he speedily took a foremost place among the teachers in the Edinburgh School of Midwifery. In 1882 he read a paper to the society on a difficult face case where he had used axis-traction forceps with satisfactory results. In 1891 he read an important memoir on the principles on which the axis-traction forceps acts and gave a definite mechanical construction to the instrument based on those principles. He afterwards read papers on forceps with adjustable axis-traction and forceps for occipito-posterior positions of the vertex. He advocated a modification of the forceps with which his name deserves to be associated permanently and which consists in having the traction bar fitted on the traction rods at different carefully measured distances nearer the handle, or further from it, according to the inclination of the pelvis. Another paper was on a Form of Post-partum Incontinence of Urine and its Treatment by Faradism. In later years he advocated the value of electric currents in the treatment of uterine fibroids and other pelvic diseases. His inventiveness showed itself in improvements in electric apparatus and the managers of the Royal Infirmary made the best of choices in placing him at the head of their newly instituted electric department. He contributed many papers to various journals; one especially might be referred to—that on the Physiological and Therapeutic Effects of Water at Different Temperatures, with special reference to Obstetric and Gynæcological Practice. It was a model of scientific work and placed the employment of the hot douche as a hæmostatic on a physiological basis. He filled with diligence, dignity, and courtesy the different offices of secretary, vice-president, and president of the society. His summing up of a discussion was often singularly illuminative and when he had occasion to criticise—and he could at times be keen and trenchant—his criticism was never unkind. His introductory and valedictory addresses as president were eloquent, pregnant with instruction, and presented with the charm of a rare literary style. Professor Simpson concluded by saying that the memory of a life so unselfish, so strenuous, and inspired by such high ideals would long remain as a stimulus to noble effort.—As a tribute to Dr. Milne Murray's memory the meeting of the society was adjourned for a month.

Society of Anæsthetists.—A meeting of this society was held on March 4th, Mr. C. Carter Braine, the President, being in the chair.—Dr. G. B. Flux read notes on a Case of Post-anæsthetic Coma in a patient, aged 40 years, who was anæsthetised for an hour by the A.C.E. mixture preceded by ethyl chloride. Death occurred on the fourth day. The urine contained a trace of albumin and many granular casts. On post-mortem examination the kidneys and heart were found to be diseased seriously and in the brain were the remains of old emboli. The patient had, curiously enough, never remembered having had a day's illness in her life. The anæsthesia was uneventful. Dr. Flux suggested that the coma (uræmic) was due to the general disturbance caused by the severe operation, an amputation of the breast.—Miss L. B. Clapham, M.B., related a similar case in which death occurred after four days. The patient was a stout woman, the operation being repair of an umbilical hernia. The A.C.E. mixture was given for an hour, followed by ether for three-quarters of an hour. The patient never recovered consciousness but vomited and became cyanosed and restless and the respiration became stertorous and of the Cheyne-Stokes type. Bronchitis and dilated heart ensued. Post mortem were found old mitral disease, diseased kidneys, great congestion of the brain, and three small cortical hæmorrhages.—Dr. Dudley W. Buxton and Dr. J. F. W. Silk discussed these two cases.—The President communicated a case of Goitre in which Nitrous Oxide was given and subsequently Ethyl Chloride. A young, healthy-looking woman was given nitrous oxide for the extraction of teeth. During deep anæsthesia asphyxia ensued without apparent cause. The patient recovered when laid horizontally and then an engorged goitre was discovered which had been concealed by the mackintosh apron. After an interval ethyl chloride was administered most successfully, as also on two subsequent occasions. The President suggested that the neck should always be exposed as far as the suprasternal notch in all administrations. He believed that in this case there was a sudden occlusion of the trachea from downward pressure on the goitre and that this was relieved when the patient was on the floor. The tongue probably had been somewhat pushed back and the jaw depressed in getting a good hold of a lower molar tooth.—Dr. A. G. Levy showed an adaptation for Administering Ethyl Chloride by Clover's Ether Inhaler. A graduated glass tube was cemented into the vulcanite stopper of the inhaler and the dose was then sprayed into the tube which at first was dependent and then inverted. The ethyl chloride vapour was gradually mixed with air by rotating the inhaler as far as the point marked 3. The indicator was kept at this point until the wished for degree of narcosis ensued. Ether could afterwards be added to continue narcosis.—Dr. Dudley Buxton then read a paper entitled "Some Reflex Dangers in Early Narcosis."—The discussion on this paper was adjourned.—Afterwards the annual general meeting of the society was held. The reports of the council and treasurer were read and adopted. The following officers were then elected for next session: President: Mr. Carter Braine. Vice-President: Dr. Silk. Treasurer: Dr. R J. Probyn-Williams. Members of Council: Mr. Harvey Hilliard, Dr. T. D. Luke (Edinburgh), and Dr. J. Blumfeld. Honorary secretaries: Dr. W. J. McCardie and Mr. H. O. Crouch. Honorary auditors: Miss L. B. Aldrich-Blake, M.D., and Dr. C. J. Woollett.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on March 2nd, Dr. J. S Bury, the President, being in the chair.—Dr. I. Walker Hall read a paper on the Effect of Decapsulation on Kidneys in which a degenerative nephritis had been induced. He said that the removal of the capsule in such conditions was always accompanied by laceration of the cortical tubules and hæmorrhage. In from eight to 14 days later the kidney capsule had formed once more and was thicker than the normal capsule. The hæmorrhages and lacerations were replaced by cellular tissue. The details of capsular changes in two human kidneys after partial removal of the capsule were given.—Mr. E. Stanmore Bishop read a paper on Gall bladder Surgery. He attributed the recent impetus to surgical work in this region to three things—namely, asepsis, clearer diagnosis, and improved technique. The older teaching which laid stress in cases of biliary calculi upon the presence of tumour, jaundice, intermittent pain, results of exploratory puncture, the discovery of calculi in fæces, and sensations of grating was ins[illegible] was usually abs[illegible] and deeply se[illegible] puncture was [illegible] dangerous. Jaundice was frequently absent; when present it was evanescent and in all cases it depended upon the position of the stone. Pain might be of two kinds—namely, either continuous and dull aching or intermittent, sharp, and intense. The latter was followed by tenderness and this was utilised in the two tests of Robson and Murphy both of which Mr. Bishop had found trustworthy. Improvements in technique included the free exposure of the biliary tract to sight and touch by careful separation of adhesions and occasionally by rotation of the liver. The danger of undue traction upon the vena cava was pointed out. Immediate and thorough clearance of all calculi was recommended in preference to the earlier two-stage method. For the control of hæmorrhage chloride of calcium and adrenalin were useful. Mr. Bishop's remarks were based upon an experience of 31 cases.—Dr. Ernest S Reynolds mentioned a family in which the eldest daughter had died insane, the second daughter had aberrant disseminated sclerosis, the third child (male) had [illegible] sclerosis of the ataxic [illegible] (female) and the fifth child (male) were normal, and the sixth (male) had aberrant disseminated sclerosis. The father had recently suffered from melancholia, his first cousin (once removed) had died from disseminated sclerosis, and a distant cousin of the last had exophthalmic goitre Dr. Reynolds mentioned also the case of a girl who had both disseminated sclerosis and exophthalmic goitre fully developed at the same time.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on March 4th, Dr. P. McBride, the President, being in the chair.—The President showed a Knife for Slitting up the Tonsil of the Lacunæ and a Pair of Punch Forceps for Removing the Stumps of Polypi.—Dr. E. Furniss Potter showed a case of Immobile Right Vocal Cord in a youth, aged 19 years. The condition was probably of a tuberculous nature, though there were no definite signs of disease in the chest or sputum.—Dr. A. Smurthwaite showed a specimen of Tuberculosis of the Larynx and Trachea of rapid course in a man aged 67 years.—Dr. H. Tilley showed three cases in which radical operations for Empyemata of the Accessory Sinuses had been carried out. All three cases had been severe in their symptoms and the final result of operation in each case was cure.—Dr. J. Dundas Grant showed a case of Ulcer of the Tonsil, probably the primary lesion, in a young woman with well-marked cutaneous syphilides; also a case of extreme Laryngeal Œdema in a man, probably secondary to tertiary specific lesion, and treated by mercurial inunction and local incision (nearly recovered).—Dr. Atwood Thorne showed a man, aged 32 years, with Adhesion of the Soft Palate to the Posterior Pharyngeal Wall. The interest of the case was that when first seen there was a mere pinhole aperture but that instead of the opening closing it had without operative interference become larger month after month, apparently by contractions of the adhesions towards their fixed points in the periphery.—Mr. R Lake showed a case of Chorditis Tuberosa and a woman with Tuberculous Ulcer on the Left Vocal Cord.—Dr. W. H. Kelson showed a girl suffering from a Nasal Sinus situated about an inch from the tip in the mid-line.—Dr. Fitzgerald showed a man, aged 34 years, with a Swelling of the Right Ventricular Band and a small Papillomatous like Growth on the Anterior Margins of the Right Cord He also showed a patient, aged 28 years, who had suffered from what he considered to be Necrosis of the Premaxillary Bone.—Dr. William Hill said that in his opinion the sequestrum was not the premaxilla itself but the Stensonian portion of the premaxilla.—Dr. H. J. Davis showed a patient with a Large Swelling between the Arytenoids and an Œdematous Mass of raised Mucous Membrane resembling a large mucous polypus and extending below the cords. The question was whether the case was one of acute œdema resulting from syphilis alone or one of mixed tuberculous and syphilitic infection.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held in the board-room of the Victoria Infirmary, Glasgow, on March 3rd, Dr. Thomas Richmond being in the chair.—Mr. A. Ernest Maylard delivered an address on Abdominal Surgery, Retrospective and Prospective, based on 14 years' personal experience in the wards of the Victoria Infirmary. The growth in numbers of abdominal operations performed per annum was traced through the period, demonstrating the marked and rapid [illegible] that had taken place in this respect. Treating chiefly [illegible] with which Mr Maylard [illegible] recent years, numerous [illegible] operations not dreamed of but a short time ago were now successfully performed. Congenital hypertrophic stenosis of the pylorus, chronic gastric catarrh, gastric ulcerations simple and malignant, idiopathic dilatation of the colon, mucous colitis, &c., were treated of and the operations for their relief or cure were described. More than a dozen cases of operations upon the stomach were shown, comprising a most striking one of gastro jejunostomy performed five years ago for pyloric obstruction due to adhesions following upon chronic gastric ulcer. The patient is now in robust health, actively engaged in his occupation, and without any symptom referable either to his stomach or any other organ. Prior to the operation in May, 1899, he had been a chronic invalid for years, much emaciated and weakened, and totally incapacitated for work on account of gastric trouble Other cases illustrated the incisions employed in various gastric and intestinal operations.—Dr. E. Duncan and Dr. G S Middleton, who spoke afterwards, were of opinion that surgery had gone an unnecessary length in the treatment of the diseases of the stomach and especially in the case of chronic dyspepsia and chronic gastric ulcer.—Mr Maylard, in reply, referred the speakers [illegible] Dr. Russell's statistics concerning gastric ulcers and urge[illegible] physicians to watch such cases throughout a period [illegible] years and to note the ultimate results which were, [illegible] felt convinced, much more serious than were genera[illegible] supposed.

WIGAN MEDICAL SOCIETY.—The annual [illegible]ing of this society was held on Feb. 18th, when [illegible] following were elected office-bearers for the ensuing [illegible] President: Mr. J. Chronnell. Committee: The Presi[illegible] Dr M Benson, Mr. T. M. Angior, Dr. J. Blair, Dr. F. [illegible] and Mr. Wolstenholme. Honorary treasurer: Mr. E. Monks. Honorary secretary: Mr. W. Berry. A series [illegible] Clinical Photographs illustrating Nervous and [illegible] Diseases was shown on the screen by Dr. E. Reynolds.

Reviews and Notices of Books.

Diseases of Women. By ALFRED LEWIS GALABIN, M.A., M.D.Cantab., F.R.C.P.Lond., Consulting Obstetric Physician to Guy's Hospital, &c. Sixth edition, with 284 Illustrations. London: J. and A. Churchill. 1903. Demy 8vo, pp. 695. Price 16*s.* net.

So many years have elapsed since the appearance of the last edition of this work that the present volume is practically a new book. Considerable additions have been made and detailed descriptions with illustrations have been introduced of the modern methods of performing the various abdominal, vaginal, perineal and gynæcological operations. Dr. Galabin's extensive clinical experience and his long association with students, both as a teacher and as an examiner, render him peculiarly fitted to write a work on gynæcology. This new edition has many merits, not the least of them being the fact that it contains a judicious mixture of old and new theories and modes of practice. At the present day, when surgery plays so large a part in most text-books dealing with diseases of women, we are inclined to forget that a great many gynæcological patients can be quite efficiently treated by medical measures alone. The author has laid due stress upon this important fact and yet all the most approved surgical methods of treating such cases will be found in the book.

As an antiseptic for general use in gynæcological work Dr. Galabin recommends lysol and points out that if it be used with cold boiled water it will remain clear enough not to obscure the instruments. In sewing up the abdominal wall he prefers three layers of sutures, the first passing through the whole thickness of the abdominal wall and of the two remaining layers one uniting the anterior layer of the fascia of the rectus muscle and the other the skin. The view that only the most superficial layers of the mucous membrane are thrown off during menstruation is taken, and an illustration of a section of the mucous membrane of a uterus during menstruation removed by hysterectomy is given which tends to confirm this view. In the chapter on Stenosis of the Cervical Canal it is a pity that the author has allowed so many figures of old-fashioned metrotomes to remain. Although their use is not recommended the mere fact that they are figured will lead the student to attach an undue importance to them. In discussing the effect of cold in rendering the uterus more vulnerable to the action of organisms which under normal conditions are only saprophytic in character a very interesting case is related in which muco-purulent discharge issuing from the cervical canal in a virgin, so severe as to suggest a suspicion of gonorrhœa, was found to contain almost a pure culture of the influenza bacillus. In very virulent forms of septic endometritis leading to purulent peritonitis the author says that the most rational form of treatment would be to remove the uterus by vaginal hysterectomy, thus getting rid of the primary focus of infection. The best chance of saving life by this means would be to perform the operation as soon as the diagnosis of septic peritonitis had been made. It is recommended that in cases where the patient is not likely to live through a hysterectomy the tubes should be ligatured as they are often the avenue of infection. The interesting question of the etiology of cases of chronic endometritis is very fully discussed in the chapter devoted to this subject. That there is a microbic origin for at any rate some of these cases is undoubted but in many instances where organisms can no longer be found changes in the nutrition of the tissues, either of a hyperplastic or degenerative character, often remain. In other cases it is suggested that the condition may not be due to any organism but to trauma, to some toxin, or even to nerve influence alone.

The author prefers intraperitoneal shortening of the round ligaments to Alexander's operation, since it affords a reasonable certainty of cure with the least disturbance of the normal relations. Under what is called adenoma of the uterus Dr. Galabin records the fact that he has removed by enucleation multiple encapsuled tumours of the fundus uteri which were thought to be ordinary encapsuled fibroids but which presented the microscopic structure of adenomatous tumours. It seems extremely likely that these tumours were really adeno-myomata. We fail to find any mention of this interesting variety of fibroid tumours of the uterus in the account given of those tumours, nor is there any reference to such tumours in the index.

The operative treatment of fibroid tumours of the uterus is considered very fully and the various methods of removing them, both ancient and modern, are described in detail. Indeed, in this chapter we think the long description devoted to the use of the wire écraseur and the details of Apostoli's method of treatment might have been eliminated with advantage. In considering the causation of a pelvic hæmatocele attention is drawn to the fact rather likely to be overlooked at the present day—viz., that intraperitoneal hæmorrhage from inflamed peritoneum, from the lining of a Fallopian tube without any evidence of tubal pregnancy being present, and hæmorrhage from an ovary have been demonstrated by abdominal section to occur. It is, however, extremely doubtful if such a condition is ever due to reflux of blood from the uterus, or to excessive bleeding from a ruptured Graafian follicle, as has been described by some writers.

Dr. Galabin's well-balanced judgment has enabled him to present the two sides of many debateable questions with much fairness and as a result of this the whole work forms a very valuable addition to gynæcological literature and will be of much value to the practitioner, to the student, and to the gynæcologist. The illustrations are on the whole very good, many of them being reproductions of the beautiful drawings in Dr. C. Hubert Roberts's Outlines of Gynæcological Pathology. There are some, however, which might have been omitted with advantage, as, for example, the very poor drawings of a sarcoma of the ovary on p. 527. The page has been enlarged to a much more convenient size than that of former editions.

The Nutrition of the Infant. By RALPH H. VINCENT, M.D. Durh. London: Baillière, Tindall, and Cox. 1904. Pp. 295. Price 10*s.* 6*d.*

IN his work entitled "The Nutrition of the Infant" Dr. R. Vincent has made an ambitious attempt to improve on the ordinary methods of modifying cow's milk on the percentage system. It must be remembered, however, that no matter how elaborately cow's milk may be modified it can never be converted, or even approximately converted, into human milk. Indeed, the more closely we attend to the chemical properties the more likely are we to lose the physiological resemblance. The infant who derives his nourishment from the natural source has this advantage over one who is artificially fed—namely, that the extremely complex molecular combinations which exist in his food, such, for instance, as the natural ferments of milk, the various proteid constituents, and the combined salts, have not been disintegrated and disorganised by the disturbing processes connected with artificial modification. If cow's milk is to be used as a substitute for human milk, and if it be admitted that modification of its chemical constituents is necessitated by reason of the differences which distinguish the one from the other, then surely our first object should be to secure chemical similarity at as little sacrifice of the physiological properties of natural milk as is possible in the circumstances. Now a considerable part of Dr. Vincent's book is taken up with a description of a method of home modification which is practically the same as that employed in milk laboratories. He proposes to adjust the differences which exist between cow's milk and human milk by a series of manipulative processes which must very seriously interfere with the normal molecular combinations existing in fresh milk. For the preparation of his accurate percentage mixtures he requires a cream which has been separated by centrifugalisation, and further he requires a cream-free milk which is also obtained by the same mechanical means. In the next place, for many of his mixtures he requires whey which can only be obtained by the action of rennet. The three chief constituents, therefore, of his mixtures are preparations of milk which have all been seriously tampered with so far as their natural physiological properties are concerned. By the graduated combination of these stock materials and by the addition of milk, sugar, lime-water, and distilled water specimens of modified milk may be prepared of almost any desired percentage composition, and not only is the total percentage of proteids thus completely under control but the relative proportions of whey-proteids and caseinogen may be modified at will. No doubt it is often a very great advantage to be able to reduce at will the bulky coagulum of cow's milk but even this advantage can be obtained at too great a cost. The general principle of percentage modification is probably perfectly sound; in fact, it is the only possible method of obtaining accuracy and securing uniform results, but for our part we regard a method so complicated as that suggested by Dr. Vincent as calculated to defeat the very ends which it has in view. In other respects we regard Dr. Vincent's little book as altogether admirable. He supplies complete directions for modifying the food in accordance with the needs of the infant and he describes at length the normal development of the child and the general methods of testing and examining the physical condition of children.

The Purification of Sewage and Water. By W. J. DIBDIN, F.I.C., F.C.S. Third edition, revised and enlarged. London: The Sanitary Publishing Company, Limited. 1903. Pp. 379. Price 21*s.*

MR. Dibdin was one of the earliest champions of the bacterial system of purifying sewage and his interest in the matter took a very practical shape in the experiments which he undertook in the capacity of chemist to the London County Council on the bacterial treatment of the London sewage at Barking Creek in 1892. In 1887 Mr. Dibdin referred to the possibility of bacterial agencies being employed to do the work of purification and his observations were met with considerable scepticism. Now not only has the chemical treatment of sewage been given up in a great many places in favour of bacterial methods but the question had become of such importance that a Royal Commission was appointed to inquire into this subject four years ago and its labours are not yet at an end. Mr. Dibdin's view of the work of this Commission may be quoted from his preface. "What the ultimate decision of the Commission may be," he writes, "it is impossible to forecast with safety, but from the information available in their official reports and the cross-examination of witnesses it is clear that bacterial systems have 'come to stay' and that the desired result may be secured by either of several methods of applying that principle and that the natural process of the survival of the fittest will gradually result in the establishment of certain methods applicable to different classes of sewage with certainty and success." Mr. Dibdin knew from the results of his early experiments at Barking Creek that the attitude which he adopted was amply supported by practical results and we cannot fail to recognise that he has done much to bring the system of purification of sewage by bacterial agencies to its present satisfactory position. The volume before us in the light of these facts is calculated to be valuable and, as a matter of fact, we find the author's practical experience of various schemes fully detailed. He has also taken the opportunity of giving full information upon the subject by summarising some of the more important evidence given before the Royal Commission on Sewage Disposal. The first five or six chapters are practically historical and give an account *de novo* of the advances that were made with bacterial methods. In subsequent chapters he deals with the bacterial treatment as applied to effluents containing trade waste. The questions of purification of rivers, the discharge of sewage into the sea, and the filtration and examination of potable water are all adequately dealt with in succeeding sections. Finally, there are chapters on the action of soft water upon lead, the absorption of atmospheric oxygen by water, analyses and their interpretation, and the ventilation and deodorisation of sewers. In the appendix the author describes a micro-filter which he has devised for estimating the quantity of suspended matters in drinking water—a method which has given important data in regard to determining whether waters under examination have been exposed to contamination.

It is quite obvious that this book will serve as a very valuable source of reference upon the subject of purification of sewage by organisms. It will be of service to those interested both in the theory and the practice of the resolution of complex waste injurious compounds into simple innocuous substances. The sanitary engineer and the bacteriologist will, as a matter of course, avail themselves of the very practical and valuable experience recorded by Mr. Dibdin.

The Physiological Feeding of Infants. By G. ERIC C. PRITCHARD, M.D.Oxon., M.R.C.P.Lond. Second edition. London: Kimpton. 1904. Pp. 197. Price 3*s.* 6*d.* net.

THERE is a weakness of construction in this book disclosed by the secondary title "A Practical Handbook of Infant Feeding and Key to the *Physiological Nursery Chart*," for the author has essayed the difficult task of attempting to combine a thoroughly professional treatise for physicians with an elementary handbook on the feeding of babies for the use of "nurses," by which term is meant not the modern dignified attendant on the sick, but the more humble, though possibly more important, servant who rules in the nursery. As a consequence there is much matter in this volume which spoils its taste when read by the trained student of pediatrics, such as the painstaking explanation of the term "percentage" and other elementary expositions, while, on the other hand, there is a good deal of commentary, excellent and sound in itself, on such points as the inherited attributes of offspring, which is most useful for the parents but which it is not always advisable to place in the hands of an imperfectly educated woman.

Half the volume is devoted to the artificial feeding of infants and the bulk of that space is filled by a careful consideration of the teaching of Rotch and the practical and simple combinations arranged under his influence in the modern milk laboratories pioneered by the Walker-Gordon laboratories in America. The modified milks prepared according to Rotch's formulæ are now obtainable in London from several of the dairy companies; the elements of the reconstructed milk are (1) cream containing 16 per cent. of fat; (2) separated milk freed from its cream by centrifugal process; and (3) milk sugar, in a standard 20 per cent. solution. These constituents can obviously be combined in any proportion and tables have been constructed, one of which is given by Dr. Pritchard in full, showing the percentage composition of milk which should, as an average experience shows, be employed during each week of the first year of infancy. The author recommends the use of the forms for prescribing the variations in the constitution of this "built-up" milk which are issued by the dairy companies; in these the percentage of each constituent is given and to the laboratory employés is left the working out of the amounts of each constituent in any given quantity for each day's service. In order to make it possible for a nurse to combine the standardised constituents at home a further table is given of the quantity of milk, standard cream, and milk sugar necessary to make one pint of percentage mixture for each week of life. Dr. Pritchard points out, we think wisely, that there is no advantage in using a syrup of milk sugar, but that the solid sugar, which may now be purchased in pound tins, can be quite easily measured by bulk and is in this form more easily protected from decomposition

No claim is made in the volume that this system of preparing standardised milk is perfect; the author is quite alive to its dangers and limitations, to which attention has in the last six months been drawn in contemporary periodicals by Dr. T. D. Lister, Dr. H. Ashby, Dr. E. Cautley, and others. These writers have, however, rather approached the subject from a democratic point of view and have shown the risks attending the haphazard issue of "humanised" milk from municipal depôts. Dr. Pritchard is writing for the well-to-do classes in large towns and he accentuates very clearly the important point that the use of these artificial milks must be in the hands of physicians and nurses with some skill to recognise when the feeding is at fault The lack of skilled supervision of the infant is already bringing into discredit praiseworthy efforts on the part of many municipal bodies, so much so, that some municipalities, such as Liverpool and Battersea, are already making attempts to get their local medical charities to supervise the results of their municipal infant feeding.

Some 60 pages, and they are the best in the book, are devoted to the forms of modification of milk necessary to suit different physiological requirements. Excellent illustrative cases are given of the conditions which should, to the watchful attendant, indicate errors of digestion or absorption: vomiting, its causation and forms; abnormalities in the stools; constipation, its manifold causation—such points are considered with care and knowledge. The temptation which is so often presented to practitioners by those in charge to combat habitual constipation by drugs, enemata, and suppositories is wisely avoided in these pages and its true cause and proper correction are indicated. The directions for testing the conditions of general nutrition, such as the proper increase in weight, the state of the skin, the muscular development, and the condition of the anterior fontanelle, are given in such terms that any intelligent nurse should be able to appreciate them. The necessary modification of food in difficult cases has led the author to introduce many elaborate preparations and formulæ, most of them excellent, but the danger in a work of this kind presents itself that parents and nurses might dabble in them without expert instruction. Such preparations as Prideaux's casumen, virol, or Lahmann's vegetable milk have undoubtedly a great value when properly combined with ordinary milk for infants who present inferior powers of absorption, but unskilled authorities in the nursery should not be allowed to play with them.

The second half of the volume contains a large body of suggestive observations on the development of infants which are not found in most text-books of disease as manifested in childhood and it is well worth careful perusal. The general style of the author's writing is simple, straightforward, and phrased with care. We have no hesitation in saying that no practitioner will regret the expenditure of the small sum which the book costs and that its careful perusal will well repay the time spent thereon.

LIBRARY TABLE.

Compounding and Dispensing made Easy: an Aid for the Promotion Examinations in the Subjects for Non-Coms. and Men of the Royal Army Medical Corps By H. Harold Scott, M.B. Lond., Lieutenant R.A.M C. London: Gale and Polden, Limited. (Military Series.) 1904. Pp. 316. Price 7*s.* 6*d.*—Before the author of this little work entered the army he held the appointment of assistant demonstrator in materia medica and pharmacy at St. Thomas's Hospital. He might therefore be supposed to be unusually well fitted to write and to instruct on a subject which while not requiring any original work yet needs to be presented in as attractive a form as possible In studying such a subject the arrangement of the different sections and the grouping of the preparations are of the greatest consequence in facilitating progress. Mr. Scott's book is an expansion of the notes which he has been giving to the members of his classes of would-be military compounders and he has published it owing to complaints from members detailed for classes of instruction that the subjects laid down in the syllabus for their examination were not to be found in any one book and that they knew not where to look for them. The present work embraces all the points required with the exception of the elementary chemistry. The book is divided into six sections. The first is purely introductory; it is full of encouragement and impresses that golden rule in dispensing, "Be careful, clean, and accurate"; it also contains useful paragraphs on the incompatibility of drugs and the explanations of the Latin and Greek terms which compounders may expect to meet with. The five subsequent sections deal respectively with: (2) Inorganic Materia Medica and the Carbon Compounds; (3) Pharmaceutical Processes and Groups of Pharmacopœial Preparations; (4) Organic Materia Medica, Vegetable and Animal; (5) the Commoner Forms of Poisoning, their Symptoms and Treatment; and (6) the Army Forms used by Compounders. It is evident that the author's early training as a teacher has been of the greatest service; the arrangement of the materials in the book is excellent, the information is correct, and the whole tone is judicious. A feature of the book is a number of tables which show the sources of many of the preparations and which must tend greatly to facilitate study. The section on Poisons is short but the symptoms and directions for treatment are clearly set forth. Useful directions are also given for the cleansing and sterilising of surgical instruments and sponges and for the keeping of rubber instruments. We congratulate the author on his work and we are glad to see that an officer of the Royal Army Medical Corps has had the good sense to produce such a book—it must prove to be most helpful to those for whom it is intended.

Studies for the Bakehouse. By A. Kirkland (Irvine). London: The Baker and Confectioner, Limited. 1903. Pp. 172.—This book contains a series of lectures, 19 in all, which were delivered before a practical class in Ayrshire. The author takes a sound position in enjoining upon his readers that special attention should be given not only to the sanitary environment under which bread is made but also to the choice of materials and machinery. Bread-making, says the author, is not a lost but a new art. To this statement we imagine that a good many people might demur with reason, for it cannot be said that the average white loaf of the present day, made by machinery or by hand from roller-milled flour, is as good as the bread of a generation or so ago. Presumably it is the fault of the public that a white loaf is demanded but we have our doubts as to whether this is so, for expressions of regret may be heard on all sides that the old-fashioned farmhouse loaf with its rich nutty wheaten flavour and golden colour is as extinct as the dodo. Even when some people take the trouble to make bread at home the flour is generally of the anæmic order in spite of improved methods of milling. In saying this we do not detract from the value of this book, for the author has pursued his subject on sound scientific and hygienic lines. We should, however, like to have seen the question touched upon of the old farmhouse loaf made from the old fashioned ground flour *versus* bread made from the roller-milled article. It may be a heresy but the empirical loaf is regarded by many with more favour than that prepared on exact lines. It should be added that some medical men have advanced the idea that the flours imported from America have something to do with the prevalence of appendicitis and it is stated that some of these flours yield hard pellets of gluten which it is thought may possibly start the inflammatory process.

New Conceptions in Science. By CARL SNYDER. New and revised edition. New York and London: Harper and Bros. 1904. Pp. 361. Price 7*s* 6*d*. net.—We reviewed the first edition of this book in THE LANCET of Oct 31st, 1903, p. 1239, and there is little to add that could be fresh criticism in regard to the second edition the issue of which has so quickly followed the first. Beyond a little revision of phraseology here and there, there is no difference between the two editions. The book is an American view of the relations of science and progress and on the whole the story is told in a bright and attractive way, though perhaps the author occasionally falls into a line of interpretation which is a somewhat elastic presentation of actual facts This is a common tendency of popular disquisitions on scientific progress.

Food for the Tropics. By T. M. MACKNIGHT. London: W. Thacker and Co. 1904. Pp. 116. Price 3*s*. 6*d*. net — This is a valuable book and, as Mr. Macknight implies in his preface, fills a gap. We are glad to see, also, that he lays stress on the point that the indigenous products of a tropical country are more suitable food for the inhabitants than any which can be imported from a country having a totally different climate. The food stuffs described in the book are classified into those which are eaten respectively for their hydrocarbons, proteids, fats, sugars, salts, and for their flavour and carminative properties, such as spices and curry powder. The book is a useful addition to the cuisine of a household in the tropics.

Calendar of the University Correspondence College, 1903-04. Cambridge: Burlington House. Pp. 64, plus 142 Price 1*s* net.—Besides the usual contents of an educational calendar the one before us contains a number of examination papers with their solutions. We may point out that the solution to the first question in the paper in English is rather confusing, for the question set is to write an essay on the mountain ranges of *Europe*, while the solution talks about the mountains of the *Old World* and says that "the great axis runs from the coast of Spain to the Pacific seaboard" In the next paragraph the student is told, "Nothing higher than Mont Blanc." Such a muddled solution as this would not be much help to the ignorant seeker after knowledge. Otherwise, so far as we have tested them, the solutions are clear.

Recent Excavations in the Roman Forum, 1898-1904 By E. BURTON BROWN. London: John Murray. 1904. Pp. 223 —Rome, Athens, and Constantinople are the three cities about the history of which no educated man is ever tired of hearing and every year adds to our knowledge of the first two if not of the last named. Mrs Burton Brown's little book, which is prefaced by an introduction written by the Commendatore Boni who has been in charge of the excavations, gives a very clear account of the findings in the Forum during the period with which the work deals. From a medical point of view the most interesting discovery was that of the fountain of Juturna which was almost from the first credited with healing properties and became in comparatively late times, 293 B.C., connected with the cult of Æsculapius. Of the many other objects of interest we have no space to speak but we would counsel anyone who goes to Rome in a proper spirit to provide himself with this little book and to use the information therein contained wisely.

JOURNALS AND MAGAZINES.

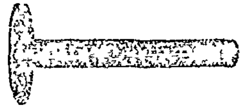
The Practitioner.—The issue of this journal for March continues the series of articles relating to Typhoid Fever. A contribution upon the diagnosis of that disease from the pen of Dr. Claude B. Ker contains a careful discrimination of the many conditions that have to be considered as well as a strong defence of the value of the Widal test which Dr. Ker pronounces after three years' experience to be practically infallible. Dr. Ker ascribes much importance to the bronchitis and the epistaxis of the early days of the illness from a diagnostic point of view. Dr. Arthur Whitfield's lectures on Eczema are concluded in this number. The illustrations are disappointing, a fact which appears to us to be usually the case when it is attempted to reproduce the appearance of lesions of the skin by photographic processes. A series of cases of Cancer of the Mouth and Fauces by Mr. Stanley Boyd and an excellent monograph on Black Urine by Dr. A. E. Garrod are also contained in this issue.

Medical Electrology and Radiology.—This journal, which is the official organ of the British Electro-Therapeutic Society and is now entering on Volume V., will from the beginning of the present year be published monthly instead of quarterly as hitherto. The change is made chiefly with a view of enabling the reports of the proceedings of the Electro-Therapeutic Society to be placed in the hands of members more promptly than before. Several excellent articles begun in the January number are continued in February—such as the review by Dr. W. S Hedley, the editor, on the Advances made in Electricity and Radio-activity in 1903, Dr. George Herschell's Practical Lessons in the Treatment of Affections of the Gastro-intestinal Tract by Electrical Methods, and the Proceedings of the Thirteenth Annual Meeting of the American Electro-Therapeutic Association. The annual address delivered by Sir Isambard Owen at the conversazione of the British Electro-Therapeutic Society is reported in full in the January number. The February number contains editorial remarks on M. Blondlot's "n" rays and the first instalment of an article by Mr. Clarence A. J Wright on the Methods of Application of High-frequency Currents.

New Inventions.

INDIARUBBER ANTRUM PLUG.

FOR some years I have had made for me a solid indiarubber plug in sizes corresponding to the English catheter gauge Nos. 3 to 12. I found that they were more comfortable and satisfactory than the hollow metal tubes. At first I had trouble in getting them made sufficiently strong and at a price suitable for all classes of patients. Messrs. Mayer and Meltzer, of 71, Great Portland-street, London, W., have now undertaken to supply them, moulded in one piece and at a reasonable price. The round shield on



the base can be cut to any shape, so allowing them to be used both for the operation through the alveolar process and above in the canine fossa. After the operation opening has closed to the required size the plug is inserted, the shield being cut wherever it appears to press uncomfortably. The patient is then given a Higginson syringe with a soft catheter attached corresponding in size to the plug selected. This forms an effective and convenient apparatus for daily washing out the affected cavity.

Harley-street, W. CLAUD WOAKES.

FROM

THE LANCET LABORATORY.

CASTOREUM BROMIDE.

(AGENCY: HARTMANN, HOHMANN, AND CO., MOULTON-STREET, STRANGEWAYS, MANCHESTER, AND 33, SEETHING-LANE, LONDON, E.C.)

THE formula of this preparation is novel, comprising bromide, valerian, and castor. Its employment is suggested in nervous disorders and hysteria and in particular it is stated to have been prescribed successfully for epilepsy, chorea, and sleeplessness. "Castoreum bromide" consists of an effervescent powder and affords a convenient way of taking two drugs which are disagreeable to the taste. Castor is rarely prescribed now, although it has some reputation as serving to control the spasms of hysteria and other convulsions.

ANTURIC BATH SALTS.

(THE ANTURIC SALTS COMPANY, LIMITED, 12, SUFFOLK-STREET, PALL MALL, LONDON, S.W.)

This preparation, according to its vendors, is the solution of the great problem—gout. The "remedy" proves to be a powder composed principally of carbonate of sodium with a trace, probably as an impurity, of common salt. Our readers will know what value as a remedy for gout to set upon this article, the price of which is 3*s.* 6*d.* per tin. We advise those sufferers from gout who are quoted as having given testimonials in favour of this preparation to try carbonate of sodium which is much cheaper. A pinch of salt might be added to the bath in order to imitate more closely the Anturic preparation. Patients are advised by the Anturic Salts Company to take care before getting out of the bath to place a wet towel over the side in order that they may take a firm grip on emerging as the "Anturic salts combining with the matter exuded by the skin render the body slippery." There is no warning given as to the probably harmful action of the strong alkali contained in these "salts" upon some skins.

"ATOMO" CIGARETTES.

(S. COHEN AND CO, 1 AND 2, SNOW HILL, LONDON, E.C.)

The tobacco of the cigarettes examined has been subjected to a strong draught of air which removes adherent sand, clay, light fluffy particles, and other mechanically adherent matters. The tobacco leaf is thus not only improved in colour but in flavour also when smoked. The effect of the process is clearly demonstrated in the following results of analysis. The untreated tobacco contained 12·05 per cent. of mineral matter, of which 4·15 per cent. proved to be sand, &c. The tobacco subjected to the forced draught contained 10·75 per cent. of mineral matter of which 2·65 per cent. was sand. The process thus removes nearly 50 per cent. of useless and probably irritating mineral matter. The dust so removed proved to contain 29·65 per cent. of mineral matter of which no less than 21·30 per cent. was fine sand. It is not only mineral matter that is removed, for on microscopical examination particles of fibre were observed as well as a fluffy material which might easily prove to be a source of irritation to the throat. It is possible that cigarette smokers derive an inflamed throat from drawing into the mouth the irritating light and easily removed particles present in the tobacco leaf. Some persons state that though they are inveterate smokers of the pipe or cigar and suffer no inconvenience thereby their throats are at once affected when they smoke cigarettes. The removal of dust by this process indicates that it is a possible factor in such cases.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 18, 1826.

LONDON MEDICAL SOCIETY.

THE Anniversary Meeting of the Members of this Society was held on Wednesday last, at the London Coffee-house, when the *following ORATION*[1] *on the Study of the Human* Mind was delivered by Dr. HASLAM.

Of ordinary minds, the memory consists, for the most part, of *excited recollections*, and the character of this faculty in animals seems to be wholly of this nature. Study, in its proper sense, is the fixation and endurance of the attention to any particular subject, and this attention, as has been before observed, is a voluntary act, acquired by repeated and even painful exertions. If we attentively watch the proceedings of our own minds, even under the endeavour to pursue a subject of delighting investigation, we become shortly aware that we are interrupted by external circumstances distracting the attention, or by the intrusion of reveries, entirely irrelevant to the direct object of our meditations, which frequently engage us so earnestly, that the original subject escapes beyond the power of immediate recovery. Since, by a candid confession, these intrusions to a greater or less degree are common to all minds, we must consider the control or voluntary power which the intellect can exercise over its thoughts, so as to confine and direct them, to be the highest effort of human perseverance and attainment. It is this concentration of mind and promptitude of thought—this undiverted pursuit of the desired object, that persuades in council, rallies in debate, averts impending disaster, and, in the moment of perilous conflict, turns the balance to victory. The nature of volition, in a medical point of view, is of the greatest importance, nor is it less interesting in a moral aspect, for the just consideration of this subject will tend to throw additional light on tremor, paralysis, chorea, tetanus, and other morbid affections of the same class; it will explain the states of sleep, dreaming, and somnambulism, and conduct us to the proper investigation of those affections of the intellectual part of our nature, that render man incompetent to exercise his volition, or disqualify him for the management of himself and his affairs; for it is evident that man, as a responsible agent, is equally involved by the determinations of his will, in committing such actions as he ought to avoid, and in leaving undone that which it is his duty to perform. In the successful prosecution of this subject, we may expect a nicer discrimination between crime and insanity than has been hitherto established, and anticipate the explosion of that baneful doctrine of the mind's unsoundness, the mischievous contrivance of forensic subtilty, the refuge of ignorance and the tool of fraud—the blazon of materialism, an insult to common sense and a libel on the Christian religion.

---

[1] Only a portion of the report of the oration has been transcribed. A footnote states that "This Oration was received with reiterated shouts of applause."

PROPOSED CENSUS IN 1906.—At a meeting of the Royal Statistical Society held on March 15th it was announced that the council of the society was about to represent to the Board of Trade the desirability of taking a census in the year 1906 instead of waiting till 1911. A motion on the subject will probably be submitted to the House of Commons.

THE LANCET.

LONDON: SATURDAY, MARCH 19, 1904.

The Homeless Poor of the Metropolis.

SOME years ago a subject such as this might have been regarded as almost alien to the pages of THE LANCET but the gradual expansion of the subject of public health and a growing recognition of the intimate association which obtains between certain diseases, such as tuberculosis, and poverty, overwork, and under-feeding have opened up channels for inquiry which formerly were regarded as being outside the sphere of influence of preventive medicine. Moreover, the admirable efforts of Mr. CHARLES BOOTH and Mr. B. S. ROWNTREE to call public attention to the conditions under which the poor of this country labour and live have awakened an intelligent interest in these problems. Mr. ROWNTREE'S figures with respect to the number of persons in York who are without the means to purchase the "maintenance of merely physical efficiency" suggest extended inquiries in other directions with a view to ascertain how far these conditions of deprivation are prejudicial to the public health. Indeed, many of the more scientific exponents of preventive medicine are beginning to recognise that in promoting the resistance of the individual they may be doing more for the progress of the public health than by devoting all their energies to coping with special diseases.

In the matter of absolute destitution Mr. SHIRLEY MURPHY has recently made some investigations which are of considerable interest. Most Londoners are aware that night by night the figures of the apparently homeless may be seen huddled together upon seats on the Thames Embankment, in Piccadilly, and elsewhere, but hitherto we have had a very vague conception of the proportion which this social malady bears either to the population as a whole or to that uncertain margin of it which is nightly to be found in the lodging-houses and shelters of this great metropolis. Mr. SHIRLEY MURPHY has therefore attempted, with the aid of the inspectorial staff of the London County Council, to estimate the number of those who are at least so near an actually penniless state as to be unable to afford a night's rest in a bed. The fact that these unfortunate people are bedless does not of necessity imply that they are also penniless. It is not unlikely that in some instances they elect to spend the only pence they possess on food rather than on a bed; the former is necessary for the maintenance of life, the latter is not. It seems that the homeless of London are for the most part to be discovered between 1 and 5 A.M. and that their peregrinations are largely confined to an area bounded by Hyde Park on the west, the further end of Whitechapel-road on the east, High Holborn, Old-street, and Bethnal Green-road on the north, and on the south by the river Thames. The destitute gravitate to this area because within its limits there are numerous and capacious common lodging-houses, Salvation Army and other "shelters," and last, but not least, free suppers. Moreover, the theatres, markets, and printing offices offer opportunities for the casual labourer or the loafer which are not afforded elsewhere. The night selected for the census of the bedless was Jan. 29th last, on which night 23,443 persons slept in the common lodging-houses of London. Of this number 21,058 were single men, 1517 were single women, and 390 were married couples. But before 12.30 A.M. these places contained a larger number than this. It is the custom in the East-end to allow all who wish to do so to congregate in the spacious kitchens of the common lodging-houses, and to enjoy the warmth of the fire. But at 12.30 the London County Council insists that those who are not prepared with the necessary bed hire must pass out into the street. In obedience to this summons there shuffled out on the night of Jan. 29th no fewer than 832 single men, 11 single women, and seven married couples. Those who witnessed this sorry exodus are not likely to forget it. These "turn-outs," as they are called, appear to join one of the streams flowing in different directions to places where the charitable organisations are accustomed to dispense free meals of soup and bread and, having accepted the hospitality of one centre, some of them may be seen making for another centre which opens its doors a little later. After this the homeless walk the streets or seek the shelter of railway arches, staircases, or doorways, and with a downpour of rain the streets empty and the staircases fill. On the night of Jan. 29th, and within the limits above referred to, the officers of the London County Council counted just under 2000 of these homeless wanderers. Are these 2000 persons habitual loafers who, night in, night out, thus rest and are fed, or does the *personnel* of this crowd vary nightly and represent, as it were, the wrecks of the day's work, the units of which differ from night to night? Do the tides of life of these unfortunate people on one day rise above the bed-line and on another ebb below it? Again, does this figure of 2000 represent an average state of affairs for the winter months or is it an indication of abnormal distress? To what, too, would the summer census amount? According to the lodging-house keepers, who have met to consider the situation, there are nightly in their houses many vacant beds, and it is stated that at a lodging-house recently erected by the London County Council to accommodate 600 lodgers at 6*d.* per head per night there have been recently but 90 applicants. Others allege that the dimensions of the army of the destitute are the result of the higher standard insisted upon by the London County Council and of its inflexible rule that, whatever the elements, those who are unable to pay must seek the streets at midnight. But all those who are familiar with the admirable reforms effected by the London County Council in the lodging-houses of the metropolis will be in no hurry to see the former unsatisfactory state of affairs reproduced.

An extension of the inquiry initiated by Mr. SHIRLEY MURPHY is required with a view to ascertain in what manner the present eminently undesirable state of affairs may be remedied. Those who have read Mr. BRAMWELL BOOTH'S sympathetic and practical letter in the *Times* will be in agreement with him as to the necessity of further inquiry. The facts that it is alleged that there were hundreds of sixpenny beds vacant on the night in question and that at the Salvation Army shelters, where the beds cost but *2d.* or *3d.*, from 400 to 500 men willing to pay were turned away suggest that in philanthropy alone will the solution of the difficulty be found. It would have been instructive if the figures of each of the shelters had been furnished. According to Mr. Bramwell Booth the cost of providing accommodation for these 2000 homeless ones would involve, on the present standard, a capital expenditure of from £80,000 to £100,000 and he suggests that half that sum should be borrowed on the security of the property which it would represent and half should be contributed by the public—i.e., that the whole should, directly or indirectly, be thus contributed. Of course, the question at once suggests itself, What is the difference between this and the Poor-law? But Mr. Bramwell Booth thinks that if a man can afford only a penny he should be provided with some sort of accommodation. Would he still maintain his point if the man had but a farthing? The problem is one of very great difficulty. Above all, we must not promote degeneration, and it is this thought which makes us hesitate to accept Mr. Bramwell Booth's humane and obviously not impracticable proposals. What we desire to know is, whether many of the 2000 are incapable of work. There is need of workers in many parts of the British Empire and a quarter of the sum proposed would transfer these homeless ones to places where they could have both work and a home. There are, too, "labour colonies" nearer home to which those who are physically capable of work might be transported at a very small cost.

◆

O'Duffy v. Jaffe, Surgeon Dentists, Limited.

Attention was called in a letter published in The Lancet of March 12th, p. 754, to the unfortunate result of the prosecution in Ireland of certain unqualified persons practising as dentists and of the company under the name of which they so practised. It is, of course, well known both to the medical profession and to the public that it has been the policy of the legislature with regard to medicine and dentistry to order the registration of qualified practitioners and to punish those using titles implying registration. In like manner under the Pharmacy Acts for England and Ireland no one may keep open shop for the sale of poisons without qualification and registration and the use of such titles as "chemist and druggist" by unregistered persons is forbidden. The evasion, however, of all such provisions has for long formed a subject for the ingenuity of the quack and the charlatan who are naturally hampered in their efforts to advertise themselves by restrictions upon the use of the most desirable and appropriate titles, and one of the means which the unregistered person has adopted in these circumstances seems to have been suggested by the development of the law of limited liability and by the legal recognition of what are known as "one man companies," a term the meaning of which is obvious.

The quack has found it easy to obtain the number of signatures necessary for registration; he has selected such a name as that in the heading of this article, possibly incorporating his own patronymic, and under it he has carried on dentistry or whatever form of practice he may have chosen. This he has done and no doubt will do still more in the future, relying on the contention that a joint-stock company cannot be registered as a medical man, a dentist, or a pharmaceutical chemist, and that consequently it cannot by the use of any name or title imply that it is so registered. This view has been before the courts before and has now been upheld by the King's Bench Division in Ireland which has ruled that the word "person" in the Dentists Act, 1878, relates only to an individual and does not embrace a corporation or company and that a company by assuming a name which includes the words "surgeon dentists" does not become liable to a prosecution under the Act for using a name, title, addition, or description implying that it is registered under the Act. This decision is in accordance with previous ones in England and in Ireland[1] and, in so far as it is undesirable for trading associations of laymen to be formed for the purpose of practising medicine or dentistry, or for the sale of drugs by the agency of their nominees or employés, these cases make it clear that alteration of the law is necessary. But the Jaffe case and the others referred to (which were concerned with the sale of drugs) do not go so far as to give entire immunity to the unregistered person, although the company which he registers may as such be unassailable. The London and Provincial Supply Association and Boyd and Co. both employed qualified persons to keep their shops and to compound and to sell their drugs and in the former case the qualified person was a shareholder in the company. It was held in that case that whether the word "person" in a statute could be treated as including a corporation depended upon consideration of the object of the statute and that the defendant associations were not liable to prosecution as if they had been persons, but it was at the same time pointed out by the House of Lords that if the persons actually dispensing poisons were found not to be registered they could be prosecuted for the offence as individuals and that in this way the public would not be without protection. Looking at the Jaffe case from this point of view we might certainly have expected to find that any unregistered person of the name of Jaffe, or of any other name, pretending to practise dentistry would have been convicted as a matter of course in a court of petty sessions upon proof that he performed his operations and received payment for them in a house with such an inscription on the door as "Jaffe, Surgeon Dentists, Limited."

Those responsible for the prosecution on behalf of the Irish branch of the British Dental Association left nothing undone, so far as we are aware, in order to attain this end, for they summoned two individuals as well as the company. We do not know what the evidence may have been as to one of them, M. L. Jaffe, but as to the other, distinguished as S. Jaffe, it was proved that a man went to a house with his daughter and saw a person upstairs who, in reply to a question, said that he was the dentist and who afterwards extracted a tooth from the girl. He received for this a fee of 2*s.* 6*d.* and gave a receipt for it signed "S. JAFFE." The house had over its door the inscription "JAFFE, Surgeon Dentists, Limited," and on a brass plate at the side of the door the words "London and New York Dental Institute, conducted under the supervision of Messrs. JAFFE, Surgeon Dentists, Limited." There was also evidence of a newspaper advertisement of "JAFFE, Surgeon Dentists," from which, apparently, the word "limited" was omitted. With this evidence before them the Limerick magistrates were of the opinion that the defendants did not either of them personally take or use the word "dentist" or any other term implying registration and they dismissed the two complaints with £1 costs in each case. This was a finding of fact and as the defendant's counsel pointed out at the hearing of the appeal it was not open to the court to review it. We cannot do more in criticising it than say that local magistrates do, not infrequently, arrive at conclusions from which other people differ, and that we hope that such a finding will not have the effect of preventing other prosecutions in similar circumstances elsewhere. In the *Times* of Jan. 9th will be found the report of a case heard at the Bow-street police court where the prosecution of an unregistered person practising dentistry was based upon the insertion of advertisements in newspapers under the name "Dental Institute, Limited." This was clearly not so strong a case as that heard at Limerick but Mr. FENWICK, the magistrate, convicted the defendant as an individual, although he recognised that the company, registered for the purpose of evading the Act, could not be held to have committed an offence under it. This, again, was a finding of fact against which successful appeal would not be easy and the conclusion to which these two cases lead us is that the registration of a company for the purpose of sheltering unqualified practice affords but imperfect protection to him who uses the device. He may be convicted of using a name or title implying that he is registered or that he is a practitioner recognised by law if there is evidence to show that he has done so, whether the name or title so used forms part of the registered name of a company or not. The question is one of fact for the bench and some prosecutions may fail where others succeed. On the other hand, in order to prevent companies from engaging in medical or dental practice under speciously selected names legislation is undoubtedly needed but to the protection of the unwary against quackery the legislature is not easily moved.

The Treatment of Operation Wounds.

THE recent Lettsomian lectures of the Medical Society of London were of no little interest for they were the well-considered opinions of an acute surgical mind on the most important problem in surgery—that is to say, the treatment of operation wounds. Operations nowadays hold the foremost place in the treatment of disease, for in addition to those lesions always looked upon as surgical many conditions formerly acknowledged by all to be in the domain of the physician are now equally certainly handed over to the treatment of the surgeon. Mr. C. B. LOCKWOOD, the Lettsomian lecturer, took as his subject Aseptic Surgery in Theory and Practice, and his conclusions are greatly enhanced in value by the fact that he gives very fully the reasons for his opinions. It is often thought that antiseptic surgery came into the world fully formed like ATHENE from the head of ZEUS and that it was incapable of development and evolution. The case, however, was far otherwise. The first beginnings of antiseptic surgery were based on the idea that suppuration in a wound is entirely the result of the presence of micro-organisms and all the means that Lord LISTER devised and employed were directed to the sole end of excluding so far as possible the entrance of micro organisms into a wound and of killing all those which might have already gained entrance. The cleansing of the surgeon's hands and of the hands of his assistants, of the patient's skin, and of the instruments and dressings employed was effected by the use of antiseptics. Elaborate means were also adopted to exclude from the wound micro-organisms floating in the air and to destroy those in the wound itself. The employment of solutions of antiseptic substances for flushing the wound and, above all, the use of the carbolic spray were based on the idea that many minute organisms are falling every minute from the air into the wound. It is undoubtedly true that large numbers of bacteria and moulds fall continually into every open wound but experience has shown in the first place that the majority of these are not pathogenic to the human body and the truly pathogenic microbes in the air are comparatively few in number and, in the second place, that the living tissues are capable of dealing with a certain number of even pathogenic bacteria, especially if there has not been left in the wound any non-living exudate in which the bacteria can develop. All the changes which were made in his method by Lord LISTER have been the result of experience. The carbolic spray has disappeared to the great comfort of the operator and his assistants and to the relief of the anæsthetist who in many operations, such as laparotomies, received no small share of the spray. Thus antiseptic surgery has undergone true development, true evolution. It discarded details which were shown by experience to be unnecessary. The dressings were modified and new antiseptics and antiseptic dressings were devised. All these changes were made with one definite idea: to simplify antiseptic treatment without sacrificing the perfection of the results.

Some 15 years after the epoch-making introduction of Lord LISTER'S "antiseptic" method "aseptic" surgery was first heard of as a rival. Without doubt an antagonism was intended between it and the "antiseptic" surgery of Lord LISTER. It was put forward as a new method by which better results could be obtained than those that followed the "antiseptic" practice, and many, even in the medical profession, have imagined that there is some essential difference between the two methods, very much in the same way as in more recent times an enthusiastic but unknowing public hailed with enthusiasm the introduction of the "bloodless" method of LORENZ for the reduction of congenital dislocation of the hip as the dawn of a new era in surgery. Even if all that is claimed in theory for the "aseptic" method were true it would be nothing more than a further stage of evolution of "Listerism." In the true meaning of the word "aseptic" it is extremely probable that no such thing as an absolutely aseptic wound ever existed. Supposing even that the hands of the operator and his assistants have been freed from germs, that the skin of the patient has been rendered absolutely sterile—and these are suppositions which can probably never be realised in practice—we are yet confronted with the certainty that even in the shortest operation a few organisms at least must fall into the wound. Should the operation be prolonged the number of intruding bacteria must be very great and though formerly we may have overestimated the pathological importance of most aerial bacteria yet they are certainly not a negligible quantity. Finally, it is worth noting that DODERLEIN examined bacteriologically some cases of laparotomy at various stages and in all bacteria were present.

Since, then, an operation in which no germs can possibly gain admittance is almost a practical impossibility, what does "aseptic" surgery mean? It means simply the abstinence from the introduction of antiseptics into the wound. That the skin of the patient and the hands of the surgeon and of his assistants should be sterile is common both to antiseptic and aseptic surgery, as is also the sterility of the instruments. Whether the instruments have been rendered free from germs by boiling or by immersion in a solution of an antiseptic can make no difference if none of the antiseptic employed is carried over into the wound. The nature of the dressings applied is also of but little importance provided that they are themselves free from germs, that they exclude germs from the wound, and that they do not affect harmfully the margins of the wound or the rest of the skin which they cover. There is no reason why the name "aseptic" should not be retained so long as it is recognised that the difference is not one of principle but of means. The Lettsomian lectures were devoted mainly to a consideration of the most valuable methods of making a wound aseptic and keeping it in an aseptic condition. The best modern criterion of the care of a surgeon is the proportion of the wounds inflicted by him which heal by first intention without any trace of suppuration. This can be accomplished only by the most rigorous attention to many minute details, for Mr. LOCKWOOD well says that "every operation is a delicate bacteriological experiment." To test the efficacy of the methods employed for sterilising the skin of the surgeon's hands Mr. LOCKWOOD snips off with scissors a small portion of skin after the hands have been prepared for operation and this is dropped into a culture tube. Should a colony appear there is proof positive that the means employed were not effective in rendering the skin sterile. In this way a fairly accurate knowledge can be gained of the value of the various methods of cleansing the skin. These methods are numerous and a few years ago CARL HAEGLER wrote a book of over 200 pages on the disinfection of the skin. It is well to bear in mind that the elimination of every unnecessary pair of hands lessens the danger of infection, therefore the surgeon alone should handle the instruments, the ligatures, the sutures, and the dressings. Mr. LOCKWOOD does not like gloves in an operation as they seriously impair the sense of touch and he has found it practically impossible to complete an operation without tearing or puncturing the fingers of the gloves. The most suitable materials for sutures and ligatures were discussed and Mr. LOCKWOOD expressed the opinion that it is advisable to use catgut for the control of hæmorrhage in all septic wounds in preference to materials which do not speedily soften and disappear. Sponges and drainage and dressings were also passed in review. Mr. LOCKWOOD further supplied statistics of the results which he had obtained in his operations; he showed in what proportion of cases he had succeeded in preventing any manifestation, even the slightest, of sepsis in wounds, and the improvement in this respect which had followed a still greater attention to detail. It is on this care bestowed on the minutiæ of an operation that success in the treatment of wounds depends whether the method be "antiseptic" or "aseptic." Any advance in the future can only be made by an even more careful study of the modes in which septic organisms find entrance to wounds.

◆

The Sale of Whisky.

IN THE LANCET of Jan. 9th, p. 109, we announced that an all-malt whisky Bill was to be introduced into Parliament this session. On March 7th a Bill "to amend the law relating to the sale of whisky and to provide for the marking of casks and other vessels containing whisky" was presented to the House of Commons by Sir HERBERT MAXWELL, supported by Colonel KENYON-SLANEY, Captain BALFOUR, and Mr. J. E. GORDON. The practice of substitution in the spirit trade prevails to such a scandalous extent (a fact to which we have repeatedly drawn attention) that it is time some serious steps should be taken to check it. Only this week in an action brought in the King's Bench Division it was stated by the person who brought the action who was the manageress of a public-house, that the reason why she was dismissed was because she complained "of the mixing of bottle whisky and brandy with spirits from the Mile-end distillery." Two barmen further alleged that a bottle of whisky of a well-known firm was turned into six bottles by the aid of Mile end whisky. The jury, however, did not give credence to these statements as they gave a verdict for the defendant. The Sale of Whisky Bill represents the first attempt to bring legislative control to bear upon the sale of substitutes for malt spirit and, so far as we understand its terms, the Bill should be effective at least in securing to purchasers of whisky a clear statement as to whether the whisky supplied to them is a spirit made from barley malt alone or is in part a spirit made from unmalted grain. In considering the health aspects of this proposed measure we are bound to recognise that whisky is a very popular alcoholic stimulant; deplore that fact as we may, it has to be faced. Bad as, generally speaking, we must recognise the prevalent practice of whisky drinking to be, we cannot leave out of consideration the question as to whether the spirit generally supplied is of good quality and whether it is that which it pretends to be or that which its name implies.

The consumption of alcohol being a terribly serious factor in the health of the nation it is the duty of the nation to insure that the forms of alcohol which it chooses to drink are at least honestly described and are as free as possible from deleterious ingredients. There is a marked difference between the physiological action of spirits derived from different sources and this difference is probably to be ascribed to substances other than alcohol. The potentialities of these substances for good or for evil depend upon the materials from which the spirit is produced. When we reflect upon the great number of raw materials from which alcohol may be prepared it is not altogether surprising that this product of distillation should vary widely in regard to its physiological effects. In short, upon these raw materials depends the nature of the by-products which may contribute to the maddening effects of "drink" or which may, on the contrary, even modify favourably the action of the alcohol. Whatever may be the precise explanation of these opposite effects there seems to be a general agreement that age is essential in order to reduce spirits to a state fit for consumption. Initially, of course, an all-malt spirit is impure because it contains certain by-products of distillation and the action of a freshly distilled spirit is physiologically bad. Even genuine malt whisky must be matured, whereas grain spirit fresh from the patent still is very pure alcohol, featureless as regards flavour, and consequently age can have no advantageous change to effect in it. The fact that patent spirit does not require maturing is one very good reason—though it is not the only reason—why grain whisky is cheaper than malt whisky; it contains no by-products which long storage can modify. Grain whisky, therefore, either has to be flavoured by adding a small proportion of full-flavoured malt whisky, or else the expedient of storing it in sherry casks in which malt whisky has been ripened is resorted to. It is greatly to be regretted that the proposed Sale of Whisky Bill contains no reference to the age of the spirit. It seems to us that it avails nothing to the consumer to be sure of getting all-malt spirit when he asks for it if he cannot at the same time receive some guarantee also as to its age. The whole object of the Bill would be destroyed if, in compliance with its clauses, it were possible to supply true malt whisky so immature as to be injurious to health. The detractors of all-malt whisky might be expected for their own purposes to supply what was asked for—namely, pure malt whisky—at the same time taking care to offer an article which, though genuine, could lay no claim to the very important qualification of age. The public would complain and the obvious answer of the grain whisky dealer or blender would be, "I told you so, blended whisky is best."

We cannot anticipate that the dealer in grain whisky will object to Sir Herbert Maxwell's Bill. Practically all it requires is that casks, bottles, and taps on the counter shall be honestly labeled "malt whisky" or "grain whisky" as the case may be, the former term being used to mean spirits manufactured from barley malt and the latter spirits sold as whisky other than malt whisky. It is obvious that the blender cannot object to this requirement, since he is never tired of telling the public that grain whisky or a blend of grain and all-malt whisky is much more wholesome than a pure malt spirit, although, oddly enough, he is careful never to record upon the label of the bottle the fact that the whisky which he sells is blended with a large proportion of grain spirit. The Bill would give protection for the sale of pure malt whisky as the Margarine Act does for the sale of genuine butter. The Inland Revenue authorities know full well under the existing law the materials used in each distillation and they have by means of the permits or certificates required for the removal of spirits and the stock books which have to be kept by rectifiers, dealers, and retailers the information necessary for tracing the whisky until it reaches the retailer. The coöperation, therefore, of the public analyst and the Revenue authorities should insure honest dealing in the sale of whisky. We presume that it is considered that brandy may be left to take care of itself and that owing to a successful prosecution under the Sale of Food and Drugs Act at Glasgow where a dealer was convicted for selling a spirit as brandy which analysis proved to be not genuine, no further legislative machinery is needed. Difficulties, however, are certain to arise as further proceedings are taken in other parts of the country, chiefly with regard to the question of the power of analysis to deal with the matter. We are by no means sure that, if a sample of brandy was taken under the provisions of the Sale of Food and Drugs Act and was shown to be not genuine and an appeal to the Government referees was made, they would undertake to give an opinion; they might refuse on the grounds that chemical analysis was not sufficiently advanced to enable them to do so. We have already expressed the belief that by paying more attention to the chemical composition of spirits analysis will be found to be a trustworthy means of differentiation. We heartily approve the object of Sir Herbert Maxwell's Bill but at the same time we strongly urge upon him the desirability of making it more comprehensive, so that, in fact, it will be a Bill to amend the law relating to the sale of all spirits.

Annotations.

"Ne quid nimis."

THE SOCIAL PROBLEM IN JAPAN.

Within the past 40 years, roughly speaking, Japan has changed from a mediæval and feudal country to one imbued with all the advances of modern Western civilisation, a point which has been pressed home to European countries with great force since the outbreak of the war with Russia. But modern civilisation, as we know from bitter experience, may bring curses as well as blessings in its train and we are led to wonder whether the route of Japan's triumphant progress has not been strewn with some of that human wreckage which in Europe has ever marked the path of empire. Light is thrown upon this question in a recent work, "Le Japon, Politique, Économique, et Social," by Dr. Henry Dumolard, a former professor in the Imperial University of Tokio. Since 1868, when the present Emperor was crowned, the whole manner of life of a large proportion of the people has changed. In the words of Dr. Dumolard "luxury has enormously increased among the upper and middle classes and as a consequence there has ensued an inequality which daily becomes greater and a separation always growing more profound between the different elements of society. Under the hard effects of these changes the good nature of the people has disappeared and their classical courtesy and gentle manners have given place to the Western ways, for in Japan, as elsewhere, the struggle for existence develops egoism and cruelty." Japan, therefore, is now faced with some unsteadiness of gait with tenderness of the calf muscles, her speech was slightly stammering, and there was tremor of the facial muscles. Weakness of the legs grew more marked and distinct polyneuritis with muscular atrophy of the affected muscles supervened. The knee-jerks were absent but the cutaneous plantar reflex was lively. Her mental confusion grew worse and she remained bedridden with neuritis for some months, after which a slight improvement set in. In seven months distinct improvement began to show itself, memory began to improve, her physical weakness and incapacity disappeared, and in June, 1903, after a year's steady improvement she was discharged from the asylum as recovered. In Case 2 the patient was a man, aged 63 years, a cab-driver. He was admitted to Colney Hatch Asylum four weeks after the onset of his illness, which was probably a mild mental delirium, in the course of which he would get out of his bed at night, wander aimlessly about the ward (of the workhouse infirmary), stating that he heard cab bells ringing and demanding fares from the other inmates on the ground that he had just driven them in a cab. Here was an example, adds Dr. Cole, of an "occupation delirium," a very characteristic feature of Korsakoff's psychosis—viz., defect of observation and memory, illusions as to the identity of persons, false ideas as to his relation to time and space, and pseudo-reminiscence. His gait was unsteady and ataxic and the knee-jerks were exaggerated. There was profound loss of memory for recent impressions extending back for many months. After several months' stay in the asylum he began to improve slightly but a permanent degree of mental defect remained. Dr. Cole points out that in almost all his cases the amount of mental derangement as to the patient's position in regard to his surroundings was such as to constitute a marked delusion. His waking life was quiet and dream-like; he lived in the past and had no memories of recent events. In a case recorded by Liepmann this loss of memory was more far-reaching and extended back to about 30 years. Dr. Cole concludes by emphasising the paramount influence of alcohol as an etiological factor. Dr. Soukhanoff and Dr. Boutenko, in their contribution already referred to, state that Korsakoff was not only the first psychiatrist to draw attention to the disease but published the largest number of studies on the subject. His teachings had been accepted by Regis, Seglas, Ballet, and others in France; Jolly, Bonhoffer, and Wernicke in Germany; Krafft-Ebing in Austria; and Percy Smith and Turner in England. They also give statistical tables as to age and sex showing that the fourth and fifth decades of life are most frequently affected with this disease; that it is rare before the age of 20 years or after the age of 60 years. As regards the sexes, while the majority of cases in males occurred between the ages of 40 and 50 years, the disease was most prevalent in women between the ages of 35 and 40 years.

THE "PAINFUL PRONATION" OF CHILDHOOD.

IN a recent number of the *Gazette des Hôpitaux* of Paris Professor A. Broca has drawn attention afresh to a condition of no little practical importance. The patient, who is always a child, after a slight injury keeps the arm hanging down by the side, the elbow is slightly flexed, and the forearm is pronated so that the thumb touches the side of the thigh. Any attempt to change from this position is resisted with cries and evidently gives rise to severe pain. The condition has been described by Daverney, Malgaigne, and Chassaignac, and more recently by other writers, but there has been much uncertainty as to the exact lesion present. So complete appears to be the loss of use of the limb that Chassaignac attributed the lack of movement to some lesion of the nervous system. A careful examination of a case shows that the want of mobility of the limb depends entirely on a fear of pain, the seat of which is in the neighbourhood of the elbow, there being especial tenderness over the head of the radius. The mode of origin is wonderfully uniform. It is produced by sudden traction on the hand. Often there is a history of a fall and the injury is attributed to this but it is really produced by the effort to raise the child from the ground by traction on the forearm. The age of the patient is nearly always under five years and in most of the cases under three years. Of 189 cases only 11 were more than five years old and 141 were under the age of three years. The injury occurs in young children because they are lifted up steps or on to a pavement by the hand of the mother grasping the child's hand. Of 130 cases 80 occurred on the left side and Professor Broca considers that this is due to most people leading a child by their own right hand and so grasping the child's left hand. Of 207 cases 137 were girls and 70 were boys but Professor Broca offers no explanation of this preponderance of girls. The treatment is extremely simple. Even if nothing be done, in a few days the child's arm will have regained its mobility. However, the condition can be immediately put right by a very simple procedure The surgeon takes the child's hand in his left hand and extends the elbow and then sharply supinates the forearm. Then he bends the elbow while he presses firmly on the head of the radius with the thumb of the right hand; at the same moment a "click" is heard and the child's arm becomes perfectly mobile, the movements being restrained only by the remembrance of the pain he has already suffered. This rapidity of recovery shows that there can be no question of fracture of the neck of the radius, as has been suggested by some. Denucé has suggested that the pain is due to a fold of synovial membrane being caught between the annular ligament and the transverse ligament but this is very unlikely. It has also been suggested that the bicipital tuberosity in extreme pronation passes behind the outer border of the ulna and finds it difficult to return. This theory, also, is far from probable. Professor Broca believes that the lesion present is a subluxation forwards of the head of the radius and he thinks he can feel a slight prominence anteriorly. Unfortunately, a skiagram affords no information, for both the capitellum and the head of the radius are cartilaginous and give no shadows. There is a slight tendency to a return of the condition should the exciting cause recur but Professor Broca considers that after reduction no splint nor even a sling is needed.

BRAKES FOR TWO-WHEELED CARTS.

IN the early hours of Friday morning, March 11th, an accident occurred in London which was fortunately attended with no loss of human life although it involved a certain destruction of property and the loss of a horse. At about 3 A.M a horse drawing a cart loaded with building rubbish was being led down St. James's-street when from some cause it became frightened. The carter being unable to control it let it go and the horse and cart going fast down the hill failed to make the complete turn and dashed against the parapet of the Oxford and Cambridge Club. This gave way and the horse and the shafts of the cart fell into the area, some 20 feet below the street level. The unfortunate animal was killed. Some years ago a similar accident happened in Bedford-street when the fore part of the horse disappeared into Messrs Dent's window and cellar in the Strand. We have never been able to understand why the very simple two-wheeled brake which is universally used for two-wheeled vehicles in France is not adopted here. Now that nearly every part of London is being grubbed up or rebuilt the contractors' carts which are seen about the streets are innumerable and the strain on the horses going down a hill, such as that of Piccadilly or St. James's-street, is very great. From a merely pecuniary point of view we should have thought that it would have paid contractors to fit their carts with the brake to which we have referred. Such an appliance would save the horses and so would savĕ the contractors' money, to say nothing of obviating the chances of such an accident as that described above with its opportunities for destruction of life and property. But the average Briton is so—shall we say conservative—that he will not use anything new or to which he is unaccustomed. We think that the legislature should step in and should make the use of such a brake compulsory. It is true that some modification would have to be made to allow for the cart being tipped but surely this would not be beyond the powers of our mechanicians.

SENILE FORMS OF MENTAL FAILURE.

THOUGH old age brings with it a decline in mental as in physical power and capacity the alteration is a gradual process and is on the whole unattended by serious mental disturbance. Senile dementia is that form of mental decay occurring after the fifth decade of life, in which various forms of mental disorder of a somewhat grave character manifest themselves. It is very rare before the age of 50 years in men and it is found that at least two thirds of all patients over the age of 50 years admitted to public asylums are cases of senile dementia. In the *Journal of Nervous and Mental Disease* for February Dr. William Pickett, instructor in neuro-pathology and insanity at Jefferson Medical College, Philadelphia, publishes an article on the subject of the mental decay and disorders of old age in which an attempt is made to analyse and to classify the various forms and to furnish a practical basis for prognosis, the material studied comprising 200 cases—100 males and 100 females. Senile insanities other than dementia are rare; they comprise a delusional form and a melancholic form which are liable to occur, strictly speaking, in the pre-senile period which corresponds with the climacteric period in women (from 45 to 50 years of age) or with a slightly later period (from 50 to 55 years of age) in man. Analysis of the clinical symptoms shows that the following are the general characteristics of oncoming senile dementia: enfeeblement of attention and slowness in the association of ideas, inexact perception of relations to surroundings and to time (disorientation), marked defects of memory (amnesia) for recent events, poverty of ideas, blunting of the feelings of affection, and irritability of disposition with exacting and tyrannical tendencies. The essence of senile dementia is quantitative but irregular reduction of the mental and moral capacities and the degenerative process is usually accompanied by attacks of temporary excitement, emotional depression, and delusion, so that the superficial symptoms of mania, melancholia, and paranoia are simulated, though these affections rarely occur in old age. "Mental confusion of some degree is present in all types of senile dementia; it appears episodically in many (66 per cent. of) cases, being one cause of the familiar street wandering of such dements." The excited, depressed, and delusional types rank next in order of frequency. Physical wasting and weakness are greatest in the common or confusional type and are progressively less marked in the other types mentioned, a point which is of prognostic value. On the other hand, the depressed and paranoid types are of less favourable prognosis as regards the mental life than are the other two types of dementia. The exaltation or ephemeral excitement of some cases is not true mania; "probably, says Dr. Pickett, "true mania never arises in old age" The following table gives a summary of the symptoms and the peculiarities of conduct of the 200 patients investigated. Some of the peculiarities of conduct have a medico-legal interest as the degree of responsibility may be hard to determine.

Symptoms and peculiarities of conduct.	143 cases of the simple confusional type.	17 cases of the excited type.	14 cases of the depressed type.	26 cases of the delusional type
	Per cent.	Per cent.	Per cent	Per cent.
Street wandering.	40	24	14	12
Hallucinations.	23	12	64	85
Vertigo.	19	6	14	27
Headache	8	6	0	19
Night prowling.	8	6	28	8
Suicidal attempts.	6	12	14	16
Exaltation.	8	6	7	42
Delusions of poisoning.	2	18	7	35
Delusions of conspiracy.	2	6	7	46
Other delusions of persecution	10	24	28	38
Delusions of marital infidelity.	0	6	0	12

The delusional cases are especially important from a medico-legal point of view, as these patients may become troublesome and even dangerous to their families, though when placed in asylums they soon subside into the category of "uninteresting" senile dements. The chief delusions to which they are liable are those of persecution by unseen and malign agencies, poisoning, and marital infidelity, the last of which may cause much distress and trouble to the patient's family.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

THE following is an abstract of suggestions approved by the committee of the Metropolitan Street Ambulance Association as the basis of a plan for providing London with an efficient street ambulance service.—

1 That there should be one controlling authority responsible for a uniform and well organised ambulance service and that that body should be the London County Council.

[illegible] areas"

This

[illegible] hand

[illegible] most

advantageously carried out conjointly.

4. That where possible these ambulances *under the control of the* London County Council fire brigade should be stationed at, or in immediate connexion with, the principal London hospitals.

5 That the police should be kept efficient in "first-aid" training; should be available, as at present, for rendering first aid to the injured, [illegible] an ambulance by telephone, and taking charge of the [illegible]

[illegible] not, as

[illegible] all other

[illegible] these

[illegible]

[illegible] many

others is

[illegible] under-

provide

[illegible] removal

adequately for the [illegible]

each year.

8. That there should be no charge for the use of the ambulance.

The suggestions, it will be observed, are only set forth as a basis for a scheme and we are not quite clear as to whether the committee suggests that the whole of the work should be undertaken by the fire brigade or only that the ambulances, whether horse or motor, should be kept at the fire stations. But then we see that suggestion 4 proposes that the ambulances should be kept at, or in immediate connexion with, the hospitals. In that case where does the fire brigade come in? Everyone knows how admirably organised is the fire brigade and no doubt the machinery of that body would do the ambulance work excellently but we have not yet heard the brigade's opinion on the matter. If the fire alarm posts and the machinery of the brigade are utilised it seems to us that there will have to be an increase in the staff and more room provided in the stations for ambulances. Motors would be the best means of traction unless a separate stud of horses were provided, for the ordinary fire-engine horse, though an excellent animal for its own work, is not exactly a suitable form of motive power for the conveyance of a seriously ill or wounded patient.

ROAD-SICKNESS.

THE much-abused sea may claim in these days of fast travelling that the land has its terrors and that in all fairness the measure of blame should be more equally distributed. Since the introduction of the long Pullman dining-car (more especially on the foreign railways which are perhaps not so well laid as some of our chief lines are, though the rate of speed is at times even greater) we have heard of many instances of sickness and nausea closely resembling the forms of sea-sickness with which most are only too familiar. Passengers to the Riviera not infrequently fall victims to the peculiar motion of the long bogie carriages which are used for dining and sleeping, a thing not to be wondered at when we consider that there must be very special undulatory risings and fallings in the body of the long car which is only supported at its ends on the peculiar bogie arrangement of the wheels, whilst in rounding sharp curves the long axis of the carriage is in a different direction from that of the mechanism on which it is placed. The pitching and rolling movements which set up *mal-de-mer* are, in fact, though to a less amplitude, imitated in the luxurious wagon-lit, and if it happens that dinner is going on whilst a tortuous piece of the line is being negotiated it is not unlikely that the services of the steward will soon be requisitioned. Road-legs have to be acquired as much as sea-legs, and in the various forms of locomotion, from the jolting omnibus to the quick-stopping tube and air-braked trains, frequent opportunities arise for estimating the varying amounts of agility, clutching of stay-straps, and compensating bodily movements made by the cognoscenti in the particular class of vehicle of which they are for the time endeavouring to form an integral part. That all forms of travelling are tiring is evident from the common tendency to sleep in railway carriages, and the proverbial sleepy state of the country carter is due perhaps not so much to his early rising as to the constant work of the muscles which automatically endeavour to compensate for the surprises of their fellows in the disturbed equilibrium caused by bad roads and weak springs. If a person must live in the suburbs of London the wear and tear caused by daily travelling backwards and forwards are certainly less on the northern lines than upon the southern, with the exception of the South-Western, because of the excellence of the permanent way and the weight of the carriages. The vagaries of the travelling public are curious: some cannot ride except facing the engine or the horses, others cannot travel at all by railway, some have faint feelings when going at a high speed, others are made actually sick, and we have known the utmost confusion caused to some unfortunates by the seats opposite the direction in which the train is moving being occupied, though, curiously enough, the same feeling is not set up when the passenger can have a seat placed parallel with the direction of progress. There is reason to believe that the action upon the eye muscles of the rapidly changing parallax and the quick passage of objects that are met and left have much to do with the production of tired feelings and of headaches caused by long journeys, and great relief is often experienced by simply closing the eyes or by refraining from looking out of the windows, and if reading is to be indulged in the daylight should be chosen and a large and clear type of print selected. The morning and evening papers of the suburban travellers have much to answer for, especially when tempted by the cheapness he indulges in those printed in small type. The question of the cause of sea-sickness—and the same may be said of road-sickness or *mal-de-terre*—has never been quite satisfactorily determined. The blood system of the body is a closed circuit and it has been plausibly suggested that the pitching of the boat and the up-and-down movement of a long carriage like a wagon-lit tend to disturb the balance of the circulatory system somewhat in the same way as the mercury in the barometer rises and falls suddenly with the degree of pitching (not rolling) of the vessel. If this is the case it is not difficult to understand why faintness and sickness are set up and even why morbid apprehensions of travelling may arise. In fact, nothing more calculated to derange the viscera and the nervous system can be well imagined than the oscillatory movements of trains travelling over badly laid roads at high speed. There is a habit now much in vogue of taking very long journeys without any intervals of rest. People are so anxious to "get it over quickly" that they rush through from train to steamer, from steamer to train, without taking the intermediate break which is generally possible and which is so useful for allowing the circulation to regain its balance, the nervous system to quiet down, and the viscera to resume their normal functions. The temptation to get quickly away to other scenes and climes is great and when carried out with reasonable care is very proper, but physicians who have to order invalids abroad for the sake of their health cannot too strongly impress upon them the validity of the German byword—*immer langsam.*

THE PROGNOSIS AND CURABILITY OF EPILEPSY.

A NUMBER of recent and valuable observations bearing on the prognosis, pathology, and curability of epilepsy were contributed by various authors in a discussion on the subject at the New York Academy of Medicine, an account of which is published in the *Medical Record* of Feb. 6th. Dr. William P. Spratling, the medical superintendent of Craig Colony, New York, stated that epilepsy was curable in from 5 to 10 per cent. of cases, "but it required, as a rule, a long-continued course of treatment, never less than two to three years." From carefully investigated records of 1325 cases during the past four years he had found that 34 cases of epilepsy at Craig Colony were undoubtedly cured in that period. Epilepsy was essentially a disease of early life. In 20 of the 34 cases which were cured it began in infancy, in nine it occurred between the ages of 10 and 20 years, in four between 20 and 40 years, and in one after the age of 40 years. Psychical epilepsy was a rare affection, being met with only in four cases among 1325 patients. Of all the types of epilepsy the Jacksonian demanded the earliest treatment. Idiopathic epilepsy required long-continued care and treatment, material improvement being sometimes observed after a year. The epileptic aura occurred in 51 per cent. of all cases, the disturbance being almost invariably a "sensory" aura. There were some varieties of epilepsy which destroyed all the faculties of the mind in a very short time, while others left the mind comparatively unimpaired. The younger the patient when epilepsy manifested itself and the longer the period without proper treatment the more grave and unsatisfactory would be the prognosis as regards the mental condition. Professor Allen Starr, who followed in the discussion, said that those who treated epilepsy in dispensary and outdoor hospital practice knew how difficult it was to accomplish anything in the way of cure—even treatment of the rich under the most favourable surroundings failed to give good results. The vast majority of patients did not recover and only a small percentage improved. Among 250 consecutive dispensary cases of epilepsy seen and treated by him only one recovered and remained permanently free from fits for several (seven) years. "It was very rare," added Professor Starr, "to see a patient go for a year without either a series of attacks or at least one or two fits." The reason for this pessimistic attitude in prognosis was because epilepsy was a slowly progressive organic disease of the brain associated with congenital maldevelopment of the organ. Many of the patients showed anatomical and mental "stigmata" of degeneracy. He found the closest analogy between Jacksonian epilepsy and idiopathic epilepsy and there were all intermediate states between these two. Dr. L. Pierce Clark, assistant physician at Craig Colony, agreed with Dr. Spratling that a recovery-rate of from 5 to 10 per cent. could be obtained among "colony" patients but that in private practice a higher percentage (nearly 25 per cent.) of recoveries was obtainable. He agreed with Professor Starr that it was an organic disease. Dr. Frederick Peterson stated that 6 per cent. of cases were curable, especially when the epilepsy supervened in adult life and without such associated symptoms as hemiplegia or cerebral softening. Idiopathic epilepsy was, in respect of its periodicity, like dipsomania. Dr. Ralph Parsons took a gloomy view as to the curability of epilepsy and Professor Joseph Collins stated that he thought 10 per cent. of alleged cures was an extravagant estimate. Dr. Leszynsky approved of the "colony" treatment of epilepsy and believed that it would become more popular as public knowledge increased and ignorance died away. Dr. Bernard Sachs stated that the term "organic" disease as applied to epilepsy did not necessarily connote incurability and agreed that from 5 to 10 per cent. represented the average limits of curability under proper care and treatment.

THE INFECTIVITY OF THE TUBERCLE BACILLUS.

THE fifth annual general meeting of members of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held at 20, Hanover-square, London, W., on March 10th, when Sir William S Church, President of the Royal College of Physicians of London, made some valuable remarks. He said that the unreasoning and unreasonable dread that some people seemed to have of the infectivity of the tubercle bacillus had been strongly brought to his attention in the course of the last year. That, in his opinion, was to be deprecated and the more so because it occurred among the more or less educated classes who, unfortunately, were influenced by some of the sensational writing on the subject. Many of these persons had kept themselves at a distance from the tubercle bacillus, imagining that that was all that was necessary, and had neglected those proper hygienic measures which place them in a condition to resist the attacks of the enemy. The National Association for the Prevention of Consumption had put two lines of defence side by side. It had recommended general hygienic measures and at the same time had indicated the means by which people might specially protect themselves and the general public from the danger of infection. Sir William Church also referred to the extreme interest with which the medical profession were watching the results of the working of the plan of compulsory notification of tuberculosis at Sheffield, just as they were noting with care what the results were of the voluntary notification of tuberculosis which was proceeding in many other districts. Another point touched on by Sir William Church was the way in which the Journal of the National Association for the Prevention of Consumption had emphasised the view that sanatoriums should be inexpensive buildings, and in connexion with this he made the suggestion that it would be of great advantage if the National Association for the Prevention of Consumption would act as an advisory board to county councils, boards of guardians, and other public bodies upon the important questions of construction, sites, and situations of sanatoriums. He considered that bricks and mortar should not take up vast sums of money when inexpensive buildings would not only fulfil the same object but would do it very much better.

THE medical officer of health of the Cape Colony states that for the week ending Feb. 20th no case of plague in human beings was reported throughout the colony. Plague-infected rodents were found at Port Elizabeth and at East London, but of 254 rats examined during the week in the Cape Town and Harbour Board area none was affected with plague. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on March 11th states that for the week ending March 10th there were three cases of plague and two deaths from the disease. As regards Hong Kong, a telegram from the Acting Governor, received at the Colonial Office on March 15th, states that for the week ending March 12th there were two cases of plague and two deaths from the disease.

DR. T. W. Eden has succeeded Mr. Alban H. G. Doran as editor of the *Journal of Obstetrics and Gynæcology of the British Empire*. The success which has been achieved since the founding of this journal some two years ago is a testimonial to the merits of Mr. Doran as an editor, his wide knowledge of the literature of obstetrics and gynæcology no less than his linguistic attainments having fitted him exactly for the post. Dr. Eden has no doubt an easier task before him than Mr. Doran had, in that he has to drive a machine that is running and has not to start the machine. At the same time he suffers under the disadvantage of following an editor of unusual attainments. We wish the *Journal of Obstetrics and Gynæcology* a continuance of prosperity.

AT a meeting of the Senatus of the University of Aberdeen, held on March 9th, it was resolved to confer the honorary degree of Doctor of Laws upon Dr. C. J. Cullingworth, obstetric physician to St. Thomas's Hospital, London. A similar degree is also to be conferred upon the Right Hon. C. T. Ritchie, M.P., Mr. William Watson, the poet, Sir George Watt, the officer in charge of the Industrial Museum, Calcutta, and Professor W. Dunstan, F.R.S., the director of the scientific and technical department of the Imperial Institute. The graduation ceremony is provisionally fixed for Wednesday, April 6th.

MISS Caroline Frith, who at the time of her death was a staff nurse in St. Bartholomew's Hospital, has left to the hospital the whole of her residuary estate, of the estimated value of upwards of £2000, to show her appreciation of the benefits which she had received from her training there and of the kindness and consideration accorded to her during her four years' residence in the hospital.

SIR Lauder Brunton has resigned his position as physician to St. Bartholomew's Hospital and has been elected an honorary consulting physician and a governor. Sir Lauder Brunton has been connected for 33 years with St. Bartholomew's Hospital, having been four years casualty physician, more than 20 years assistant physician, and nearly nine years full physician.

THE annual general meeting of the Coal Smoke Abatement Society will be held on Tuesday, March 22nd, at 3 P.M., at Stafford House, St. James's, London, S.W. (by the kind permission of the Duke of Sutherland). Sir William Richmond, K.C.B., R.A., will preside.

THE annual general meeting of the Medical Graduates' College and Polyclinic will be held at the College, 22, Chenies-street, Gower-street, W.C., on Monday, March 28th, at 3.30 P.M. Dr. C. Theodore Williams will preside.

ON Wednesday evening next, March 23rd, at 8.30 P.M., Dr. Marmorek will deliver an address at St. George's Hospital upon Antituberculous Serum.

THE country has learned with sincere regret the news of the death on Thursday morning of the aged Duke of Cambridge.

WE regret to have to state that Sir Samuel Wilks has shown signs of weakness since our previous and favourable note of his condition.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the General Council of King Edward's Hospital Fund for London to receive the accounts and report of the General Council for the year 1903 was held on March 8th at Marlborough House, H.R.H. the Prince of Wales being in the chair. Those present were the Bishop of London, the Chief Rabbi (the Rev. Dr. Adler), Viscount Duncannon, Lord Iveagh, Lord Farquhar, the chairman of the late London County Council (Lord Monkswell), the President of the Royal College of Physicians of London (Sir William S. Church, Bart.), Sir Savile Crossley, Bart., M.P., Sir Joseph Dimsdale, Bart., M.P., the Right Hon. C. Stuart Wortley, K.C., M.P., Sir Trevor Lawrence, Bart., Sir John Aird, Bart., M.P., Sir Henry Burdett, K.C.B., Sir William J. Collins, Sir John Craggs, Mr. Sydney Buxton, M.P., Mr. F. M. Fry, Mr. Albert G. Sandeman, and Mr. Hugh Colin Smith.

In the absence of Lord Rothschild SIR JOHN CRAGGS presented the certified accounts of the Fund for the year ending Dec. 31st, 1903. These showed the details of the receipts to be as follows, neglecting fractions of £1: annual subscriptions, £52,834; contributions to be retained as capital, £16; donations, £8082; grant from the trustees of the London parochial charities for the maintenance of convalescent homes, £1000; contribution from League of Mercy, £10,000; received on account of the Coronation gift, but not included in last year's report, £863; legacies, £3048; income from investments, £27,639. The total receipts for the year amounted to £83,483, and the council's decision to recommend that £100,000 should be distributed among the hospitals and convalescent homes involved drawing upon the reserves to the amount of £18,751. Some particulars of the work of the Fund during the first 11 months of the year were given at an interim meeting of the council held at Marlborough House under the presidency of the Prince of Wales on Dec. 14th, 1903. A report of this meeting appeared in THE LANCET of Dec. 19th, p. 1748, and a full list of the grants and donations made by the Fund for the year was published in our issue of Dec. 26th, p. 1831.

The PRINCE of WALES having moved the adoption of the accounts, Mr. SMITH in seconding the motion, said that as compared with the year 1902 the annual subscriptions in 1903 were £4100 more, the League of Mercy gave £2000 more, and the income from investments was £16,200 more, owing to the munificent gifts of Lord Strathcona and Lord Mount Stephen, though, on the other hand, the donations were less.

Sir HENRY BURDETT, in supporting the adoption of the accounts, said that as treasurer of the League of Mercy it was a pleasure for him to point out that the £10,000 given by the League of Mercy to the Fund last year might be taken broadly as representing contributions of small sums and from this it was evident that small subscribers—in fact, the humbler people of London—were really taking a very practical interest in the Fund through the League of Mercy.

The motion was carried unanimously.

Mr. SMITH, chairman of the executive committee, read the report of the General Council for the year ending Dec. 31st, 1903.

The PRINCE of WALES said: My Lords and Gentlemen, I have much pleasure in moving the adoption of the report for the past year and on the whole I think we may be well satisfied with the results achieved for it could not be expected that the contributions to the Fund would be equal to those of the previous year—that of the Coronation. As I stated at our last meeting in December I regret very much that it has been necessary to draw upon our reserves and I trust that the ensuing year will enable us to provide £100,000 out of income without again having recourse to what may be considered an undesirable expedient. I shall be only echoing the unanimous opinions of the council in expressing our gratitude to all who, whether in large sums or small, have supported the Fund during the seventh year of its existence. As stated in the report, the investments of the Fund now standing in the names of Lord Rothschild and Mr. Hugh Colin Smith, taken at cost, comprise £234,037, while the securities received by the Fund, as valued at date of receipt, amount to £430,218, making a total of invested capital now owned by the Fund of £664,255. This position of affairs may be considered satisfactory. But we must endeavour to improve it. And I think you will all agree that we have already obtained very great encouragement when I tell you that within the last few days, to my surprise and gratification, I have received from a personal friend who desires to remain anonymous a letter which I should like to be allowed to read :—

SIR,—I regret to learn that the assured income of the King's Hospital Fund from investments and other permanent sources only amounts to about £36,000 a year, which is £14,000 a year less than, two years ago, it was hoped the fixed income of the Fund from endowments, &c., would have reached by this time. It is clear to me that there is no better way of benefiting the sick poor of London than by supporting the King's Hospital Fund, and that it is a matter of the greatest importance to the London hospitals generally, as well as to the success of the Fund itself, that it should as speedily as possible be placed in a position to enable it to make an annual distribution among the London hospitals of not less than £150,000. If the King's Fund had an assured income from investments and other permanent sources of, say, £50,000 a year, I believe that it would not be very long before the income from subscriptions and other sources would amount to £100,000 a year, making a total of £150,000 a year available for distribution, and placing the King's Fund in a position to exercise a most beneficial influence and control over the management of every London hospital. To help this most desirable object I have decided to anticipate a provision in my will and instead to hand over to the King's Hospital Fund by way of gift securities representing the capital sum required to provide one-third of the £14,000 a year deficiency on condition that the remaining two-thirds, £9332 per annum, is provided for. This offer to be good and to remain in force till Dec. 31st next, 1904. I do not attach any other conditions to this offer, but would like to express a hope that Your Royal Highness, as President of the King's Hospital Fund, may see your way to prevent any portion of the funds subscribed for the relief of the sick poor being diverted to purposes of medical education. Trusting your Royal Highness may be placed in a position to enable you to avail yourself of my offer.

As a rule I am reluctant to make personal appeals. But, having received this munificent offer, I feel that it is my duty to invoke the support of those who are in a position to follow the example of this anonymous benefactor and so enable us to secure the full results of his generous proposal. The total number of subscribers to the fund is over 4300. To this must be added the many subscribers to the League of Mercy. These statistics are satisfactory, as showing that while we receive large donations the Fund is also becoming understood and, I hope, appreciated by the people. To bring this about was the original purpose of the Fund. I take this opportunity of referring to one particular class of the community from which the London hospitals derive substantial help. I mean the dramatic profession. I sometimes think we do not fully realise how much of their valuable time is gratuitously given by the members of the stage for charitable purposes.

The report, on the motion of the PRINCE of WALES, seconded by Sir JOHN AIRD and supported by the BISHOP of LONDON, was received and adopted.

Lord MONKSWELL then moved a vote of thanks to the Prince of Wales for presiding. This was seconded by the CHIEF RABBI and after His Royal Highness had expressed his acknowledgements the proceedings terminated.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on March 10th, Mr. HENRY MORRIS, Vice-President, being in the chair.

The Council having been consulted by the Physical Deterioration Committee as to the details of a scheme for an anthropometric survey of the United Kingdom had referred the matter to the Committee on Physical Disabilities and a report was now received from that committee, in which it recommended that the Council should express its approval of the general idea of the scheme as being well calculated to elicit those facts of which a knowledge is essential to the formation of any opinion as to the physical improvement or deterioration of the race, and that the committee moreover believed that the results of the investigation would be of great scientific value and interest. It was resolved to send a reply in the terms contained in the report.

The Council expressed its warm appreciation of the very great services rendered to the Council by Mr. Thomas Bryant as the representative of the College on the General Medical Council for the long period of 13 years. The Council appointed Mr. Henry Morris as the representative of the College on the General Medical Council for five years. The chairman of the Museum Committee reported that Staff-Surgeon C. Marsh Beadnell, R.N., M.R.C.S., of H.M.S. *Powerful*, had presented to the College 13 Filipino skulls collected from the battlefields of Luzon, Philippine Islands. The best thanks of the Council were given to Staff-Surgeon Beadnell for his gift.

The VICE PRESIDENT reported the delivery of the following Hunterian lectures—viz.: three lectures by Mr. T. Crisp English on the After Effects of Head Injuries; three lectures by Dr. Arthur Keith on the Evolution and Action of certain Muscular Structures of the Heart (illustrated by specimens from the Physiological Series of the Hunterian Collection); and three lectures by Mr. L. B. Rawling on Fractures of the Skull.

The VICE PRESIDENT reported that the President had appointed Dr. John Barlow as the delegate of the College to the Congress of the Sanitary Institute to be held at Glasgow in July.

The VICE-PRESIDENT reported that the President had been placed upon the list of vice-presidents of the English organising committee for the International Congress on School Hygiene to be held at Nuremberg in April and that Dr. Clement Dukes had been appointed as the delegate of the College to the Congress.

The VICE-PRESIDENT reported that the College had been invited to send a representative to the jubilee of the University of Wisconsin to be held in Madison on the first five days of the week beginning June 5th.

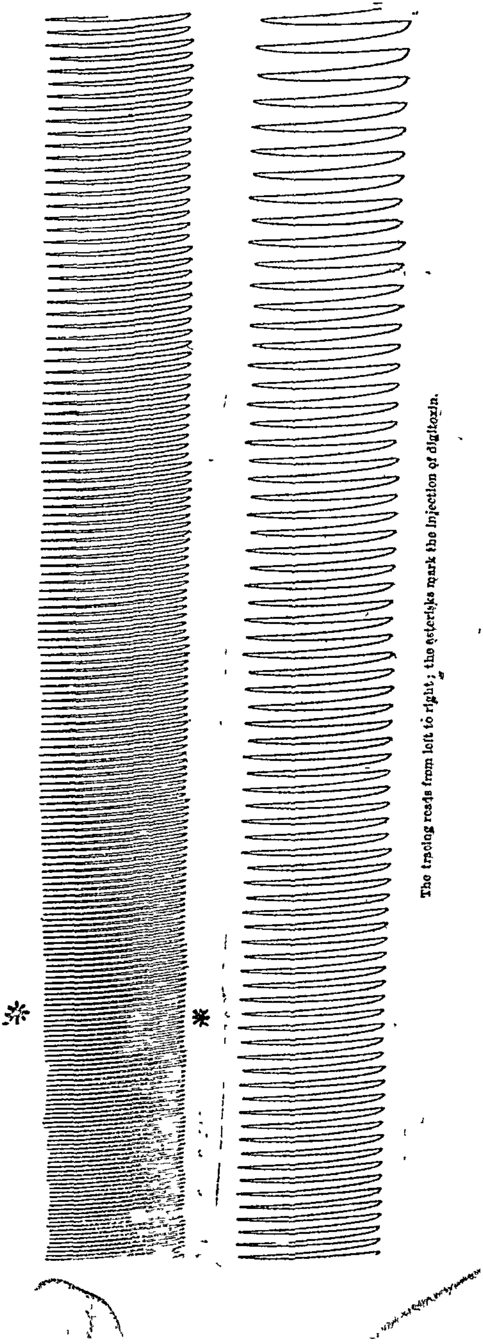
The following letter was read from the Registrar of the General Medical Council, reporting the following resolution adopted by the Executive Committee of that Council:—

> That the Executive Committee learn with regret that Mr. Bryant [illegible] of office as repre- [illegible] arch 12th, [illegible] of his [illegible], and in [illegible] an of the Examination Committee.

A letter was read from Mr. Morris resigning his membership of the Board of Examiners in Dental Surgery in anticipation of the expiration of his period of office on May 11th. The vacancy thus occasioned will be filled at the meeting of the Council in April. Mr. Morris resigned his seat on the Court of Examiners to take effect at the end of the pass examination for the Membership in April next. The vacancy thus caused will be filled at the meeting of the Council on May 12th and May 4th will be the last day of application.

AN INTERESTING DEMONSTRATION AT CAMBRIDGE.

THE accompanying figure is a reproduction of a tracing taken in the presence of their Majesties the King and Queen on the occasion of their visit to the Medical Schools at Cambridge on March 1st. The experiment, which was conducted in the Pharmacological Department, consisted in the perfusion of an excised rabbit's heart with an oxygenated Ringer's solution by a method slightly modified from that of



The tracing reads from left to right; the asterisks mark the injection of digitoxin.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Metropolitan Borough of Finsbury.—Dr. George Newman is to be congratulated upon the early appearance of an interesting annual report for 1903 and it would add materially to the value of all annual reports if they could be issued with something approaching the same celerity and, at the same time, thoroughness. In the statistical portion of the report a table is furnished as to deaths in relation to tenements and as it is of very considerable and general interest from a public health standpoint we reproduce it here :—

Finsbury, 1903. Death-rates per 1000 from all and Certain Causes in Houses or Tenements of Several Sizes.

Size of tenement.	Census population (1901).	All causes.	Zymotics.	Phthisis.	Respiratory diseases (excluding phthisis).
One-roomed tenement	14,516	38·9	5·6	4·5	9·3
Two " "	31,482	22·6	3·8	2·8	5·3
Three " "	21,280	11·7	1·8	1·2	2 4
Four " " (and upwards of four rooms)	33,185	5·6	0·54	0·63	0·84

The poorest and unfittest classes will naturally be found in the one-roomed tenements but nevertheless this table shows what an enormous factor conditions of living form in determining the death-rate and how much of such death-rate is really preventable in a social sense. We are fully aware that the usual criticisms as to age, sex, and occupation may be levelled against this table, but we agree with Dr. Newman that it points to the fact that "the conditions of life obtaining in one-room tenements are such as tend towards poor physique, disease, and death. The density of population is higher, the physical restrictions are greater, and there is less fresh air and more uncleanliness." The figures in our view tend to emphasise the fact that in better conditions of living we have perhaps the most potent instrument of all sanitary measures. Some interesting figures relative to pulmonary tuberculosis are furnished in the report before us. The history of 129 cases of the disease was investigated and in 118 the source of infection is regarded as having been a relative. In many of these cases, Dr. Newman states, the history indicated family infection through several generations, as many as four or five near relatives dying from this disease at intervals of two or three years. We are not told whether in these cases the patients were members of the same house or only of the same family. There are, of course, not a few instances on record where members of a family with a tuberculous proclivity have all died within a few years of one another, although they had not met for many years. But Dr. Newman evidently attaches importance to any opportunity for infection, however long ago it may have occurred. For instance, here is an illustration of this point. "F., 66 years. Phthisis four years. 11 years ago worked in orphanage at Bournemouth where many of the inmates were phthisical." Of course, if exposure 11 years previously is to be held to account for infection in this case it would not be difficult to find an explanation for every case that occurs, and a slight extension of this sort of argument would bring us to the views recently enunciated by Behring that infection is practically always contracted in early childhood, but that the infection remains in most instances latent until some degeneration or alteration of the tissues enables the bacillus to increase and to produce what we recognise as tuberculosis. The section of Dr. Newman's report which deals with Protection of the Food-supply is very instructive and we could wish that every annual report contained a section on the same lines. Finsbury is one of the chief centres in the metropolis for the manufacture of ice-creams and 1065 Italians, many of whom are engaged in this industry, reside in the "Italian quarter" of that borough. Much attention was given during 1903 to the subject of tinned peas, and peas which had been subjected to a "new" process of preservation came in for much discussion in the law courts. Some difficult questions were raised at the trial but the evidence tended to show that although in several cases the tins were not "blown," their contents had not been thoroughly sterilised in the first instance. Probably some sporing organism had escaped destruction. There are in Finsbury 232 restaurants and eating houses and in these 400 men and 600 women, exclusive of waiters and waitresses, are engaged in the preparation of food and some 60,000 persons resort thither daily for refreshment. Of these places not less than 68 per cent. were found defective in one or other sense during 1902—a fact which shows how important is their thorough supervision. A most instructive section on the milk-supply of the borough is furnished by Dr. Newman and all interested in the question will do well to read it. When we are told that some 1200 farms situated in different parts of the country send their milk into Finsbury it is not difficult to realise what are the risks attending the consumption of raw milk. The greater portion of the Finsbury milk is derived not from the home counties but from the great milk-producing counties of Derbyshire, Staffordshire, Leicestershire, Warwickshire, and Wiltshire—i.e., 95 per cent. of the milk coming into the district is a very considerable time in the train, the average journey from farm to milkshop being from ten to 12 hours. In many cases, indeed, the milk does not actually reach the consumer until it is 24 hours old. Dr. Newman deals with the history of the milk from the cow to the consumer and he shows in what manner it is liable to contamination at the farm, in transit, in the milkshop, and at the home of the consumer. As regards the shop attention is drawn to the risks which are run from the storage of milk in uncovered vessels in places where spices, paraffin oil, blacking, potatoes, and a host of other articles are exposed for sale. Dr. Newman regards the contamination by the repeated dipping into the milk of small receptacles as more or less inevitable, but, of course, a small churn with a tap would entirely do away with this risk. The bacteriology of milk is as yet in its infancy, but Dr. Newman, as the result of the examination of several samples collected in different parts of London and examined at once, found that the average number of bacteria per cubic centimetre ranged from 4,800,000 to 340,000, this latter number being probably due to the plentiful use of preservatives; the number of liquefying colonies per cubic centimetre ranged from 120,000 to *nil*, the putrefactive organisms including the bacillus coli communis and streptococci. The appendix to the report contains some interesting observations upon aliens in Finsbury in 1903 and Dr. Newman quotes from the recent report of the Royal Commission to show how erroneous the popular notions are as to the "dumping" of aliens on our shores. The table furnished by the Commission shows that the percentage of aliens to total population is lower in the United Kingdom than in any other country of Europe with the exception of Sweden and Spain, while in no country in Europe does the proportion approach that in the United States where the percentage of aliens to total population is no less than 13·71, as against 9·58 in Switzerland, 1·38 in Germany, and only 0·69 in the United Kingdom—i.e., the number of aliens in this country is considerably under 300,000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8908 births and 5577 deaths were registered during the week ending March 12th. The annual rate of mortality in these towns, which had been 18·5, 17·5, and 18·6 per 1000 in the three preceding weeks, further rose last week to 19·0 per 1000. In London the death-rate was 20·1 per 1000, while it averaged 18·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·9 in Tottenham, 9 6 in Hornsey, 10·3 in Walthamstow, 11·7 in Newport (Mon.), 11·8 in Leyton and in Tynemouth, 12·0 in Smethwick, and 12·3 in Reading; while the highest rates were 23·0 in Manchester, 23·2 in Birkenhead, 23·4 in Swansea, 23·5 in Brighton, 23·9 in Norwich, 24·6 in West Hartlepool, 24 9 in Wigan, and 25·8 in Preston. The 5577 deaths in these towns last week included 500 which were referred to the principal infectious diseases, against 493, 420 and 503 in the three preceding weeks; of these 500 deaths 169 resulted from whooping-cough, 148 from measles, 65 from diphtheria, 54 from diarrhœa, 31 from scarlet fever, 27 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Southampton, Reading, Great Yarmouth, Burton-on-Trent, Smethwick, Barrow-in-Furness, or Newport (Mon.); among the other towns the highest death-rates from the principal infectious diseases were recorded in Norwich, St. Helens, Warrington, Bolton, West Hartlepool, Gateshead, Rhondda, and Swansea. The greatest proportional mortality from measles occurred in Norwich, Birmingham, Aston Manor, Stockport, St. Helens, Oldham, Rochdale, and Rotherham; from scarlet fever in Warrington; from diphtheria in Portsmouth, Walsall, and Sunderland; from whooping-cough in Wolverhampton, Handsworth (Staffs.), Birkenhead, Liverpool, Bootle, St. Helens, Warrington, Bolton, Bury, West Hartlepool, Gateshead, and Swansea; from "fever" in Nottingham; and from diarrhœa in Middlesbrough. Three fatal case of small-pox were registered last week in Nottingham, one in London, one in Warrington, and one in Gateshead, but none in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 29, 31, and 41 on the three preceding Saturdays, had further risen to 54 on Saturday last, March 12th; 21 new cases were admitted during last week, against nine, five, and 13 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1601, against 1620, 1587, and 1578 at the end of the three preceding weeks; 192 new cases were admitted during the week, against 143, 150, and 153 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 349, 322, and 371 in the three preceding weeks, further rose last week to 414, and were 156 in excess of the number in the corresponding period of last year. The causes of 67, or 1·2 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bolton, Leeds, Newcastle-on-Tyne, Cardiff, and in 39 other smaller towns; while the highest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, Warrington, Rochdale, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 22·2, 21·8, and 21·2 per 1000 in the three preceding weeks, increased again to 21·5 per 1000 during the week ending March 12th, and was 2·5 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·2 in Greenock and 15·4 in Perth to 23·5 in Glasgow and 31·6 in Paisley. The 710 deaths in these towns included 21 which were referred to whooping-cough, 20 to measles, 13 to diarrhœa, five to small-pox, four to scarlet fever, four to diphtheria, and one to "fever." In all, 68 deaths resulted from these principal infectious diseases last week, against 75, 79, and 89 in the three preceding weeks. These 68 deaths were equal to an annual rate of 2·1 per 1000, which was 0·4 per 1000 in excess of the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 26, 21, and 36 in the three preceding weeks, declined again last week to 21, of which eight occurred in Aberdeen, three in Glasgow, three in Dundee, three in Paisley, and three in Leith. The deaths from measles, which had been 19, 27, and 22 in the three preceding weeks, further declined to 20 last week, and included ten in Glasgow, six in Paisley, and four in Dundee. The fatal cases of diarrhœa, which had been 18, 11, and 19, in the three preceding weeks, decreased again last week to 13, of which five were registered in Glasgow, three in Dundee, two in Edinburgh, and two in Aberdeen. The deaths from small-pox, which had been five, six, and three in the three preceding weeks, rose again to five last week, and included three in Greenock and two in Glasgow. The fatal cases of scarlet fever, which had been three and two in the two preceding weeks, increased again last week to four, of which two occurred in Paisley. The deaths from diphtheria, which had been five in each of the two preceding weeks, declined to four last week, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 167, 165, and 155 in the three preceding weeks, increased to 156 last week, and were 39 in excess of the number in the corresponding period of last year. The causes of 33, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·7, 27·2, and 26·4 per 1000 in the three preceding weeks, rose again to 28·3 per 1000 during the week ending March 12th. During the past four weeks the death-rate has averaged 27·9 per 1000, the rates during the same period being 18·1 in London and 18·7 in Edinburgh. The 206 deaths of persons belonging to Dublin registered during the week under notice were 14 in excess of the number in the preceding week and included 11 which were referred to the principal infectious diseases, against 16, 15, and 13 in the three preceding weeks; of these, six resulted from whooping-cough, three from "fever," one from scarlet fever, and one from diarrhœa, but not any from small-pox, measles, or diphtheria. These 11 deaths were equal to an annual rate of 1·5 per 1000, the death-rates last week from the principal infectious diseases being 1·7 in London and 0·5 in Edinburgh. The fatal cases of whooping-cough, which had been nine, 11, and ten in the three preceding weeks, further declined last week to six. The deaths from "fever" which had been two in each of the two preceding weeks, rose to three last week. The 206 deaths in Dublin last week included 39 of children under one year of age and 63 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were considerably in excess of the respective numbers in the preceding week. Five inquest cases and three deaths from violence were registered, and 68, or nearly one-third, of the deaths occurred in public institutions. The causes of seven, or more than 3 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1904.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·8 per 1000 of the population, estimated to be 4,649,088 persons in the middle of the year. In the three preceding months the rates had been 6·0, 5·4, and 5·1 per 1000. The rates were considerably below the average in Hampstead, Holborn, the City of London, Lewisham, and Woolwich; while they showed the largest excess in Bethnal Green, Stepney, Poplar, Battersea, and Deptford. The prevalence of small-pox last month showed a slight increase over that recorded in the two preceding months; of the 19 cases notified during the month, four belonged to Battersea, three to Bermondsey, and two each to Islington, Hackney, Bethnal Green, and Southwark. The Metropolitan Asylums hospitals contained 31 small-pox patients at the end of last month, against 40, 26, and 21 at the end of the three preceding months; the weekly admissions averaged six, against eight, four, and four in the three preceding months. Scarlet fever was slightly less prevalent than it had been during the preceding month; the greatest proportional prevalence of this disease was recorded in Paddington, Chelsea, Bethnal Green, Stepney, Poplar, Bermondsey, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 1738, 1606, and 1626 at the end of the three preceding months, had declined again to 1560 at the end of last month; the weekly admissions averaged 153, against 184, 168, and 182 in the three preceding months. The prevalence of diphtheria corresponded almost exactly with that recorded in each of the three preceding months; among the various metropolitan boroughs this disease was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Poplar, Battersea, and Deptford. The Metropolitan Asylums hospitals contained 782 diphtheria patients at the end of

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING FEBRUARY, 1904.

(*Specially compiled for* THE LANCET.)

* Including membranous croup.

last month, against 763, 734, and 752 at the end of the three preceding months; the weekly admissions averaged 107, against 109, 104, and 97 in the three preceding months. Enteric fever was rather less prevalent during February than in the preceding month; the greatest proportional prevalence of this disease was recorded in Hammersmith, Holborn, the City of London, Stepney, Southwark, and Battersea. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 286, 246, and 166 at the end of the three preceding months, had further declined to 125 at the end of last month; the weekly admissions averaged 15, against 45, 30, and 16 in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, St. Marylebone, Shoreditch, Poplar, Bermondsey, and Deptford. The 21 cases of puerperal fever notified during the month included four in Islington and two each in Hammersmith, City of Westminster, and Hackney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Feb. 27th the deaths of 5959 persons belonging to London were registered, equal to an annual rate of 16·7 per 1000; in the three preceding months the rates had been 16·2, 17·2, and 18·2 per 1000 respectively. The lowest death-rates in London last month were 11·5 in Lewisham, 12·9 in Hampstead, 13·4 in Stoke Newington, 14·0 in Kensington, 14·4 in the City of London, and 14·6 in Holborn; while the highest rates were 19·1 in Stepney, 19·4 in Bethnal Green, 19·8 in Shoreditch, 20·2 in Southwark, 20·5 in Chelsea, and 20·9 in Bermondsey. The 5959 deaths from all causes included 506 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 142 from measles, 21 from scarlet fever, 59 from diphtheria, 190 from whooping-cough, 19 from enteric fever, and 73 from diarrhœa. In the City of London no death from any of these infectious diseases was recorded last month; among the various metropolitan boroughs they caused the lowest death-rates in Hampstead, Stoke Newington, Hackney, Holborn, Finsbury, and Wandsworth, and the highest rates in Chelsea, Southwark, Bermondsey, Battersea, Deptford, Greenwich, and Woolwich. Of the two fatal cases of small-pox registered last month one belonged to Islington and one to Southwark. The 142 fatal cases of measles were 39 below the corrected average number; among the various metropolitan boroughs measles was proportionally most fatal in Paddington, Kensington, Hammersmith, Fulham, Chelsea, and Holborn. The deaths from scarlet fever last month numbered 21, against an average of 49 in the corresponding periods of the ten preceding years; of these 21 deaths, three belonged to St. Pancras, three to Lambeth, and two each to Paddington, Chelsea, Hackney, Stepney, and Wandsworth. The 59 fatal cases of diphtheria showed a decline of 102 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Stoke Newington, Hackney Bethnal Green, Poplar, and Deptford. The 190 deaths from whooping-cough were 24 below the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Poplar, Southwark, Bermondsey, Deptford, Greenwich, Lewisham, and Woolwich. The 19 fatal cases of enteric fever showed a decline of 27 from the corrected average number; of these 19 deaths two each were recorded in the City of Westminster, St. Pancras, Stepney, Southwark, Lambeth, and Battersea. The 73 deaths from diarrhœa were 20 in excess of the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in the City of Westminster, St. Marylebone, Bethnal Green, Southwark, Battersea and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was *nearly 30 per cent. below* the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 124 per 1000. The lowest rates of infant mortality were recorded in Hammersmith, St. Marylebone, Stoke Newington, Holborn, Finsbury, and the City of London; and the highest rates in Hampstead, Poplar, Southwark, Bermondsey, Battersea, Greenwich, and Woolwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Leonard Henry Kellett has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Dec. 5th, 1903).

The following appointments are notified: — Deputy Inspectors-General of Hospitals and Fleets: M. FitzGerald, C.M.G., to Jamaica Hospital and C. Pearson to Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Major R. E. Kelly, from half-pay, retires on retired pay (dated March 12th, 1904). Major J. Girvin has joined the Home District for duty. Lieutenant-Colonel T. P. Woodhouse has been appointed to the charge of the Station Hospital, Umballa.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Lieutenant M. A. Cholmeley resigns his commission (dated March 12th, 1904).

VOLUNTEER CORPS.

Rifle: The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): Surgeon-Lieutenant J. Scott to be Surgeon-Captain (dated March 12th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Maidstone Companies: Surgeon-Lieutenant Colonel J. Cantlie, 7th Middlesex Volunteer Rifle Corps, to be Honorary Lieutenant-Colonel Commandant (dated March 5th, 1904).

ANTICIPATORY ANTISEPSIS.

A war correspondent of the *Daily Mail*, referring to an interview which he had had with Dr. Wada of the hospital at Chemulpho, where there are 24 of the men who were wounded on the *Variag*, makes the following remark. Speaking of the effects of the new Japanese high explosive shells he says that Dr. Wada recommends washing the bodies of the men and disinfecting their clothing before battle to prevent the pieces of cloth causing the wounds to suppurate.

DEATHS IN THE SERVICES.

Surgeon-Major Robert William Woollcombe, A.M.D. (retired), at his residence, Ellesdee, Westbury-on-Trym, near Bristol, on March 7th, in his eighty fifth year. He entered the army as assistant surgeon in March, 1845, and joined the 68th Regiment of Light Infantry. He retired from the service in February, 1857, with the rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

RAYS PROCEEDING FROM ACTIVE MUSCLES AND NERVES.

To the Editors of THE LANCET.

SIRS,—With reference to the letter from Mr. A. A. Campbell Swinton in your issue of March 5th we willingly admit that when we commenced to make "n"-ray experiments we were not sufficiently careful to try to eliminate heat effects, but it must be remembered that he and others were at that time publicly stating they could get no results at all and were inclined to believe "n"-ray phenomena were subjective. Since the publication of our paper and the confirmation of some of our observations by THE LANCET Mr. Swinton has fallen back on the heat theory and gives heat as a sufficient explanation of the "foot" experiment mentioned in our letter, and such of Professor Blondlot's results as he has been able to repeat. The matter therefore enters into another phase. "N" rays behave admittedly like heat in many of their manifestations and we have only had time to experiment with various heat screens as a means of sifting out the heat. Although we are reasonably sure heat cannot travel through these screens rapidly enough to produce the phenomena we have seen we do not regard the matter as proved with the same certainty as the objective existence of the rays which is easily settled by putting a calcium sulphide screen in front of a large board and getting some one in front to say when an operator at the back moves his wrist up to the rear of the screen. The proof of the non-penetration of heat simply needs time and experiments and on this point we would recommend a perusal of Professor Blondlot's letter in the *Electrician* of March 11th.

We admit that the light of a calcium sulphide screen will be increased by a warm boot, whether on the foot or off it, but in direct opposition to Mr. Swinton we contend the increase of the light is *not* stopped by the interposition of a heat screen if made of a material which is opaque to heat and not to "n" rays. Ordinary cardboard absorbs and holds water like a sponge and we believe the dampness of the cardboard was the cause of Mr. Swinton's failure to see there were muscle rays in addition to heat rays proceeding from the foot. We have repeated the experiment with a shallow false-bottomed wooden box between the foot and the luminous screen and find, as in a number of similar trials, that the light *does* increase from the muscle rays. But we will not take up any more of your space with such early experiments in view of the rapid advance made on the continent each week by a number of French physicists and printed in the *Comptes Rendus*.

Since our last letter we have successfully transmitted the rays along a copper wire and perceived the dull appearance of the light when the screen is held over the poles of a permanent magnet, compared with the brighter light when in the weak field in the neighbourhood. This does not seem to us a proof that the result is due to the magnetism but it is strong evidence against the heat theory.

For the purposes of medical diagnosis the transmission of the rays by means of a wire is much the most convenient method. One end of the wire, attached to a metal button, can be placed on the muscle, while the screen, fixed at a convenient distance away, can be observed at ease. The transmission along the wire travels slowly but the increase in light is quite evident. The reason of the curious pulsation that takes place we have had no time to investigate nor have we been able to find out precisely why all our experiments are occasionally a failure, although we believe our eyes, and not the rays or screen, are at fault. At any rate, we warn readers against attempting any trials except in the early morning or after sunset unless they prepare their vision by shutting themselves in a dark room for about half an hour previously. The easiest muscle ray effect to observe is the increase of light in the screen when it is held in the right hand and the left wrist passed slowly under it. This is, in our opinion, a magnified effect due to eye or brain augmenting a real increase. Unless this can be seen it is useless for the would-be observer to make any further trials with his own eyes. He must work by deputy.

In conclusion, we may point out that the experiments of M. Gilbert Ballet described in the annotation in your last issue (p. 740) seem to us the beginning of new methods of medical diagnosis certain to be developed much further and of which we can only dimly see the importance at present.

We are, Sirs, yours faithfully,
HUGH WALSHAM, M.A., M D. Cantab., F.R.C.P. Lond.
LESLIE MILLER, A.M.I.E.E.
March 15th, 1904.

ASTIGMATISM AND "EYESTRAIN."

To the Editors of THE LANCET.

SIRS,—The letter of Dr. G. M. Gould, of Philadelphia, in THE LANCET of March 12th, p. 755, commenting upon your recent article on his views concerning "eyestrain," is one which I think should not be suffered to pass without notice from English ophthalmologists. As one of the seniors among them, I venture to offer a few observations upon the subject.

It was my privilege to be well acquainted with Professor Donders; and, shortly after the publication of his *Astigmatismus und Cylindrische Glæser*, I furnished a London monthly medical journal, then edited by the late Dr. Alfred Meadows, with what, except for the scarcely known papers of Young and Airy, was, I believe, the first general description of astigmatism which appeared in English. My attention was, therefore, early directed to the subject; and about 12 years ago, in a statistical summary of the cases of 10,000 consecutive private patients, which you were good enough to publish, I mentioned that 1400 of them, or 14 per cent. of the whole, had presented degrees of astigmatism for the relief of which cylindrical glasses were required. I therefore venture to think that I have some practical knowledge of the condition.

My experience has led me to form the following opinions: (*a*) that a small degree of astigmatism discoverable by minute examination is rather the rule than the exception in the human eye; (*b*) that in the great majority of persons an astigmatism not exceeding half a dioptre is easily corrected by the accommodation, and produces no symptoms of any kind; (*c*) that astigmatism of the cornea is often either increased or corrected by similar or opposite astigmatism of the lens, and that astigmatism of the eye as a whole may therefore either appear or disappear at the period of presbyopia, as a consequence of failing accommodation or of lenticular changes; and, (*d*) that the "eyestrain" alleged to exist in America as a consequence of low degrees of astigmatism has no parallel in the experience of English practitioners.

The 14 cases referred to by Dr. Gould do not impress me. They rather remind me of an anecdote concerning a polite and cautious lawyer, placed at the same dinner-table with a fire eating colonel who was relating his wonderful adventures by flood and field. At the conclusion of one of these, the lawyer said, "That was, indeed, a most extraordinary incident. I suppose, colonel, that if you had not seen it yourself you would not have believed it?" "I certainly should not," replied the colonel. "Ah," rejoined the lawyer, "I take entirely your view of the case. I did not see it, and so, &c." Moreover, I am old enough to remember when the many women who were poetically described as "stranded upon the shores of life" were all said to be suffering, not from astigmatism, but from ulceration of the cervix uteri, and to be curable by the local application of silver nitrate, or, in extreme cases, of *potassa fusa*. In our own day, adenoid growths have been exalted to a high place in the pathology of childhood. Like the poor, these things are always with us.

If I also may mention cases, I will select two which I have studied with some care; one of them my own, the other that of a lady whom I have known all her life. I passed through youth and early manhood with vision well in excess of $\frac{6}{6}$ths, reading and writing much, and without consciousness that I had eyes. At about 40 I recognised the beginning of presbyopia, and commenced the use of glasses for evening reading and for operating. My latent hypermetropia gradually became manifest, and before I was 60 had reached the degree of 2·50 D. At about 70, I found my distant vision to be a trifle less clear than it had been; and it was at once restored to its former condition by adding to my + 2·50 distance glasses horizontal cylinders of + 0·50. With these, in my seventy-sixth year, I still have $\frac{6}{6}$ths. I assume the appearance of the astigmatism to have been due either to lenticular changes or to the loss of the last shred of accommodation; but my point is that I have never in my life, either before the astigmatism was corrected or since, experienced a trace of ocular discomfort or incapacity.

The lady is highly hypermetropic, and suffered much inconvenience during childhood. At eight years old, she could only read in the evening by standing on a chair under a gas-burner, so as to bring her book close to the light. When she was about 20, I gave her spherical glasses of + 4 50 D and she wore them constantly, for all uses, for 20 years, and was quite comfortable. She was and is a great reader, but, with the help of the glasses, had sufficient accommodation for near work until she was about 40. At that time, a few months ago, she told me that she wanted more power for reading, and on testing her distant vision I found that, like my own, it was improved by a cylinder of + 0·50. I added this both to her distance and to her somewhat stronger reading glasses, and she sees perfectly. Her astigmatism never had any other effect than a slight diminution of her visual acuteness.

We are not without experience in London of the employment of very weak cylinders. They are often recommended and supplied by unqualified persons who advertise themselves as "ophthalmic opticians" or by similar titles, and who find in the alleged need for cylinders a plea for making high charges for the glasses which they sell. Scores of such glasses have been brought to my consulting-room at different times, with complaints of their inefficiency; complaints often due to the inadequacy of the spherical element rather than to the presence of a negligible cylinder. I am unable, nevertheless, to attach any importance to Dr. Gould's suggested experiment of putting cylindrical glasses upon a non-astigmatic person. I think it probable that the accommodation learns to mask or to overcome a congenital defect, although it might easily be embarrassed by a similar defect *suddenly and artificially produced in an adult.*

One word more. Dr. Gould tells us that "there is no more clearly demonstrated fallacy, no greater scientific error" than the opinion expressed by Professor Donders that astigmatism of less than a dioptre was seldom disturbing to vision. This opinion was neither a fallacy nor an error, but a simple statement of Professor Donders's personal experience, unquestionably trustworthy as far as it went, although, if Dr. Gould be right, the experience may have been insufficient to afford a basis for a general conclusion. But, assuming it to have been either a fallacy or an error, how could it possibly have been both? A fallacy, except in the speech and writing of the vulgar, is a sophism, an erroneous method of argument; while an error is a mistaken conclusion, to which a *fallacy* would naturally lead. To accuse Professor Donders of either, more especially of the "fallacy," is, I think, to fail in the respect due to his memory and to his great services to ophthalmology, and to commit at least an *error of taste, even if not an error of judgment.*

I am, Sirs, your faithfully,

March 14th, 1904. R. BRUDENELL CARTER.

THE MODE OF INFECTION BY NEMATOIDS.

To the Editors of THE LANCET.

SIRS,—I note the amusing suggestion by Dr. G. C. Low that I have failed to discriminate between embryo and adult nematoids but pass on to his statement that I was "peculiarly unfortunate" in referring to Manson's view that young specimens of Filaria nocturna "escaping into the water in which the mosquito died, it is through the medium of this fluid brought into contact with the tissues of man." This certainly was the commonly received view till about three years ago and at the time of writing I had unfortunately forgotten Dr. Low's interesting confirmation of Bancroft's [illegible] might be found in the [illegible] the head of Culex fatigans [illegible] This fact is now well known and has been verified by other observers.

The fact, however, by no means settles the question as to the mode in which infection by Filaria nocturna commonly takes pl[illegible] tion of [illegible] by Dr. [illegible]

partially developed worms happen to be found in the proboscis it seems by no means necessary to adopt the [illegible] parasites so [illegible]ity to enter [illegible] on man."[1] [illegible], "so far as Mr. Low's observations have gone there is nothing in them to negative the theory that filariasis is a waterborne disease," and he brings forward several well-attested facts favouring this latter supposition and opposed to the notion of direct infection through the proboscis of the mosquito.

Then, again, an important consideration advanced by Manson must not be lost sight of. He says: "My belief is that before embryos can be found in the blood by ordinary [illegible] of parent filariæ must [illegible] ny cases we know that [illegible] ent." Which mode of infection is most likely to give rise to the large number of parent worms commonly met with? The drinking of contaminated waters and the passage of embryos through the intestinal canal and into the lymphatic system would seem to favour this multiple infection more than direct infection through the proboscis of the mosquito when the embryo would be as likely to pass into the connective tissue of this or that exposed portion of the body as into one of the blood vessels of the part. I am far from denying the possibility that infection may take place in this latter way, but I believe in the more than equal probability that infection is brought about by contaminated water or food, and think it wrong that this possibility should be ignored. It was with a view to favour this consideration that I have dwelt upon my own experience as showing that young nematoids are from the first well equipped for an independent existence, that they undergo nothing worth the name of a metamorphosis and may therefore need no intermediate host.—I am, Sirs, yours faithfully,

H. CHARLTON BASTIAN.

Manchester-square, March 15th, 1904.

CHLORETONE IN SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—Permit me to thank the correspondents who have, in answer to my letter of Jan. 23rd, so kindly contributed to your columns their experiences of chloretone in sea-sickness and at the same time, if not encroaching too much on your valuable space, to make a few remarks.

It is very gratifying to learn that we have now such a reliable prophylactic against the so much dreaded sea- and train-sickness, yet it appears capriciously to fail in a few instances. These failures might be prevented were we better acquainted with the *modus operandi* of the remedy. The anæsthetic effect of chloretone on the gastric mucous membrane suggested by Mr. H. Cameron Kidd is an explanation which seems to me hardly sufficient to account for all the facts. The observation by Dr. O. Clayton Jones of its successful use in cases of nervous origin, its hypnotic effect, and the results obtained with it in my own practice seem to prove that it acts also on the nerve centres.

In one case, for example, the pains of spasmodic dysmenorrhœa, headache, and vomiting all subsided in about half an hour after administration of 15 grains of chloretone and in less than an hour tranquil sleep ensued.

The occasional failure of chloretone to prevent sea-sickness may be due in some instances to its interference with the secretion or action of the digestive ferments and, if so, that source of failure might be avoided by taking a full dose of the drug on an empty stomach and refraining from food for an hour or two afterwards. It is to be regretted that Mr. L E. Ellis did not give information on that point. Hoping that these remarks may be of service to others and that further information on this important subject may be elicited in your columns,—I am, Sirs, yours faithfully,

Seven Kings, Ilford, March 2nd, 1904. JOHN DUNLOP.

PREVENTION OF INFECTIOUS DISEASE IN BATH.

To the Editors of THE LANCET.

SIRS,—Your correspondent *Dr. Preston King*, in a letter on the above subject in THE LANCET of March 12th, p. 755, raises an important legal point with reference to infectious diseases. The point is as to whether Section 126 of the Public Health *Act, 1875, applies to measles and whooping-cough.* Dr. King also refers to diseases which are scheduled. I take *it* that he means by that term the diseases mentioned in Section 6 of the Infectious Disease (Notification) Act, 1889, and any *other* infectious disease to which the Act has been applied. If that be so, *Dr. King says*: "It is a fact, not a question of opinion at all, but simply a matter of fact," that Section 126 of the Public Health Act applies to those di*seases only* mentioned in Section 6 of the Notification Act. That is a very decided position to take up, and as Dr. King is so confident on the matter I shall be glad if he will be good enough to point out through your columns the section and Act upon which he relies. I am not aware of the existence of any section in the Notification or any other Act which limits the operation of Section 126 of the Public Health Act, 1875, to the particular diseases mentioned in the Notification Act.

[illegible] (Prevention) Act, 1890, only [illegible]

A disease [illegible] must be both dangerous and infectious. Mumps is a very infectious disorder, but not dangerous, hence the above section would not apply to it. The word "dangerous," I take it, means dangerous to life. There is no doubt but that the above section applies to scarlet fever. Are not both measles and whooping-cough as infectious diseases even more dangerous than scarlet fever? The following were the death rates for England and Wales during the past year for each of these diseases: scarlet fever, 0·12; measles,

---

[1] Brit. Med. Jour., June 16th, 1900, p. 1456.

0·27; and whooping-cough, 0·27 per 1000 respectively. Again, erysipelas is included in the Notification Act. Does Section 126 apply to it and is it a dangerous infectious disorder?—I am, Sirs, yours faithfully,

J. T. NEECH, M.D. Durh..
Medical Officer of Health of Halifax.
March 13th, 1904.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary: Opening of a New Operating Theatre; Tribute to the late Dr. Alexander Davidson.

A NEW operating theatre, the gift of an anonymous benefactor, was opened on March 9th by Mr. E. R. Bickersteth, the President of the Royal Infirmary. The gift will complete a scheme for four operating theatres and two lecture theatres, equipped with every necessary appliance and all thoroughly up to date. The new theatre, of which Mr. G. G. Hamilton will be the surgeon-in-charge, is all that is desirable. Every effort has been made to insure the maximum of light—both natural and artificial—pure air, and clean conditions of work. The appliances are all under the ready control of the operator and his assistants; in fact the simplicity of everything is most noticeable. A feature of the sterilising equipment is the absence of expensive apparatus in the basement. The close proximity of the sterilising apparatus to the operating table will be an enormous advantage to the patient, as the dressings will go straight from the steriliser on to the wound, none of the assistants, except the surgeon, touching even a needle. Mr. Hamilton gave an interesting demonstration to the ladies and gentlemen present on the simplicity of the arrangements. He laid stress on the presence of the hot steam pipes which enabled rapidity of boiling and the advantage of everything being so close at hand to the operator.—At the recent meeting of the committee of the Royal Infirmary the following motion was carried unanimously:—

> That the committee desires to place on record its sense of the great loss the institution has suffered by the death of Dr. Alexander Davidson, who had been connected with the infirmary for so many years and who took so large an interest in its rebuilding. Dr. Davidson was honorary physician from 1876 to 1897 and he was never lacking in attention to the patients in his wards who during this long period had the benefit of his great skill and knowledge. On his retirement from this position he was appointed an honorary consulting physician and by his death the hospital has lost a devoted friend.

The Liverpool School of Tropical Medicine: A Year's Results

The fifth annual report of the Liverpool School of Tropical Medicine, presented in the form of a large-sized pamphlet, records the completion of a successful year's work. The results of the teaching and operations are now beginning to appear and testimony is constantly arriving from West Africa and other unhealthy regions in the tropics that health conditions have very much improved where the recommendations of the school have been followed. The director of the school (Major Ronald Ross, late I.M.S.), had received from the general secretary of the Compagnie Universelle du Canal Maritime de Suez, Paris, a letter stating that as a result of numerous works of drainage, filling up of ditches, oiling cisterns and pits, and suppressing marshes and pools of water, &c., at Ismailia, the number of fever cases had very sensibly diminished. Complete disappearance of anopheletes had not yet been realised but insects recently captured were found not to be infected. The mosquitoes called culex had, however, been suppressed almost completely, so that in the hottest period of the year it had been possible to abandon the use of mosquito nets. Information from another source as to the actual number of cases of malaria shows that they had been reduced from 2000 in 1902 to 200 in 1903. The marked success of the experiments carried out at Ismailia had attracted much attention throughout Egypt and it was hoped that it would stimulate to increased energy those towns on the coast of Africa which remained infected by malaria. The annual cost to the Suez Canal Company for maintaining this remarkable sanitary condition was about £700. Similarly spontaneous testimony is also borne to the improvements in the general health at Cape Coast, Iquito, Peru, and other places owing to attention to improved sanitary details. The report further enumerates the various expeditions undertaken by Major Ross and others since the formation of the school and gives much interesting information regarding experimental and research work carried on in the laboratories of the University of Liverpool. The committee, while thanking generous supporters, indicates that it would be more encouraging if the number of subscribers were larger.

The Recent Small-pox Outbreak in Liverpool; History of Development; Preventive Measures and Vaccination.

Dr. E. W. Hope, the medical officer of health, has published an interesting report dealing with the conditions existent during the outbreak of small-pox in the city in the latter part of 1902 and the whole of 1903 The scourge appeared in October, 1902, and continued for 15 months, afflicting in all 2032 people. But for the extraordinary vigilance and activity of Dr. Hope and his staff greater havoc must have been caused by the loathsome malady. The prevalence in 1902 owed its origin to importations on 23 occasions by sea and on 16 occasions by tramps. During September, 1902, 15 cases occurred in the city, eight of which were directly connected with previous cases, three having been discovered at their homes by the corporation inspectors. The source of infection of six (three being found in one house) was uncertain. The remaining case was brought into the port from Bilbao. The extension of the outbreak originated with an unrecognised case in Robsart-street—an unvaccinated infant to whom no medical man had been called until it was dying from the disease after an illness of eight days. The child was actually dead by the time an intimation had been received by the medical officer of health. On visiting the house all the other occupants, six in number, were found to be suffering from the initial stage of small-pox. All were removed to hospital and the house was thoroughly disinfected by the sanitary staff. A house-to-house visitation resulted in 20 more cases being discovered by the officers, most of them being friends of the family. From this time onwards, in spite of the measures taken to check it, the disease continued slowly to gain ground; the number of cases which occurred in the vicinity of Robsart-street during the three months ending January, 1903, was 99, of which 68 were discovered by the staff as a result of house-to-house visitation. Accompanying Dr. Hope's report is a series of interesting maps and charts showing the gradual spread of the disease. From one case in Lansdowne-street the infection was traced to 29 cases. Doubt as to the nature of the illness proved another fruitful source of dissemination. Owing to the fact that a large number of cases, modified by vaccination, were regarded by the medical adviser as chicken-pox it became necessary to schedule chicken-pox as a notifiable disease in order that doubtful cases might be visited by a medical officer experienced in small-pox. The value of this measure was confirmed by the fact that 54 cases of small-pox which were under treatment as chicken-pox were discovered and dealt with. During the time that small-pox was most prevalent as many as 2000 families were visited daily by the inspectors, with the result that 470 cases were discovered that otherwise would have escaped detection. The report deals with the efficacy of vaccination and the dangers of infection carried in public conveyances, &c. The maximum number in hospital at any one time was 335 on March 19th, 1903. The report also deals with the small-pox hospitals and the Vaccination Acts.

March 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow: Honorary Degrees.

AMONG the names published of those on whom the Senate of the University of Glasgow has resolved to confer the honorary degree of Doctor of Laws (LL.D.) are two of special interest to the medical profession—viz, William Stirling, B.Sc., M D., Brackenbury professor of physiology and histology, the Owens College, University of Manchester, and Sir William Taylor, K.C.B., M.D., Director-General of the Army Medical Service, War Office, London. The graduation ceremony will take place on Tuesday, April 19th.

The Royal Philosophical Society of Glasgow.

At a meeting of this society held on March 9th Professor Robert Muir of the University of Glasgow delivered the fourth of the centenary series of lectures, the subject of his address being Some Advances in Medical Science during the Nineteenth Century. The lecturer dealt chiefly with the development of the science of bacteriology and its influence on medical and surgical practice. He passed in review the work of Virchow, Pasteur, Lister, and Koch and then dealt with some of the important events of recent years—for example, the discovery of the bacillus of plague and Ross's establishment of the mosquito cycle of the malarial parasite and the success of the American Army Commission in stamping out yellow fever. He then referred to the subject of bacterial toxins and antitoxins and the application of the latter in the treatment of disease, particularly diphtheria; also to the methods of protective inoculation introduced by Pasteur for fowl cholera, anthrax, and rabies, and their further elaboration and application in the treatment of cholera, plague, and typhoid fever; and lastly, to recent researches which had shown the existence of a class of micro organisms invisible as yet to the microscope—a subject of immense interest in connexion with those infectious diseases the etiology of which is still unsolved

Small pox in Glasgow.

The medical officer of health (Dr. A. K. Chalmers) in his last report shows that 26 patients were admitted to hospital during the week ending Thursday, March 10th, being seven more than were admitted during the previous week. The numbers are, however, diminishing, as is shown by comparing the number under hospital treatment for each of the last three weeks—viz., 157, 121, and 113.

Western Infirmary, Glasgow.

The Partick dean of guild court on March 10th passed plans for the erection of an additional wing to the Western Infirmary which it is estimated will cost £20,000. This new wing will form the first part of a new block which the governors propose to erect and which altogether will cost £100,000. This is in addition to the new dispensary which is now approaching completion. The building, the plans of which have just been passed, will give ward accommodation for 59 beds, while the other two wings required to complete the whole new block will give further accommodation for 88 beds and will include two large operating theatres and a fully equipped gynæcological department.

Reconstruction of the Royal Infirmary, Glasgow.

The first list of subscriptions to the supplementary fund opened on [illegible] he Royal Infirmary [illegible] in all to £97,655. [illegible] the new scheme hav [illegible] ves fully £100,000 still to be obtained.

Memorial to the late Professor Nicol, Aberdeen.

Dr. W. Mackie, 13, North-street, Elgin, who has been appointed secretary and treasurer of a movement for the purpose of getting up a memorial to the late Professor Nicol of the University of Aberdeen, has been doing his best to promote the scheme and a committee has been formed for the purpose of collecting subscriptions and of advising as to a suitable form for the memorial, a suggestion being that it should be a memorial brass similar to those erected to the memory of his predecessor and his successor, the late Professor Macgillivray and the late Professor Nicholson. It is felt that a suitable memorial should be erected to the memory of the distinguished stratigraphist who did valuable work during his 25 years' tenure of office in the University of Aberdeen. The members of the arts class of 1874 to 1878 are taking a keen interest in the movement.

Montrose Asylum and Infirmary.

The managers of the Montrose Asylum and Infirmary met on March 1st, Mr. J. M. Ross presiding. It was intimated that Dr. George A. Johnston, junior assistant at Sunnyside Asylum, had been appointed to fill the vacancy caused by the resignation of Dr. A. H. Cassells, at a salary of £200. The asylum statistics for February were submitted by Dr. J. G. Havelock. They showed that six patients were admitted to the institution during the month, four were discharged, one was transferred, and one had died, leaving 682 on the register at that date, of which six were voluntary patients. Of the 682 patients, 254 were from the county and 76 were from Dundee. The clerk read the infirmary statistics for February. 18 patients were admitted, 14 were discharged cured, one was improved, one was not improved, and three had died, leaving 18 patients in the house at that date.

March 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Belfast District Lunatic Asylum.

AT the usual monthly meeting on March 14th it was reported that there were 1071 (507 males and 564 females) on the asylum register. The public auditor has disallowed the expenditure which had been incurred during the year on days when lunatics had been released from the asylum. This was considered strange, as the cost on such days is generally greater than on ordinary ones and the auditor's predecessor had allowed it. It was decided to write to the Chief Secretary on the matter. A motion to place on record appreciation of the valuable services rendered to the institution by the resident medical staff (based upon Sir G. P. O'Farrell's complimentary report) was lost by the casting vote of the chairman. All spoke highly of the work of the medical staff but some could not vote for such a motion simply on the ground that it was unusual and unprecedented.

Prevention of Tuberculosis.

In connexion with the proceedings preliminary to the erection of a sanatorium in the county of Cork credit is due to the Midleton district council as the one which initiated the movement and organised the formation of a united district. 20 districts comprising the entire county united without a dissentient. This pioneer example is likely to be followed by others in Ireland.

March 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Asylums for those Temporarily Indigent.

To put an end to the overcrowding of the hospitals by chronic patients Dr. Babinski has set on foot a scheme for the construction of institutions which will occupy an intermediate position between a hospital and a casual ward and to which those temporarily ill ("*demi-malades*") may be admitted when they like, on presentation of an admission card which will be given to them after they have undergone a rigorous medical examination. If any crisis arises in their condition they will be cared for by the hospitals physicians but they will not be admitted, save only exceptionally, to the hospitals. After or between their attacks they will find shelter for the night and will be provided with food enough to remove all danger of starvation although not enough to make them anxious to remain permanently in the asylum or to take away their wish to find work. This seems an admirable plan. Those who are really infirm, the "*demi-malades*," and those who can only work intermittently will no longer find themselves confronted with the dilemma of either going into hospital where they cannot look for work or else of starving outside the hospital and the Assistance Publique will no longer waste vast sums of money for nothing. The public knowing that under this scheme any one really infirm will be helped will no longer let itself be exploited as is the case at present and will no longer provide the funds to perpetuate the evil of helping people indiscriminately. Finally, it goes without saying that the sham poor and the malingerers will be rapidly put an end to. Some such institution as that just described is all the more necessary in view of the fact that the Prefect of Police has just made some modifications in the casual ward (*dépôt de mendicité*) at Nanterre. Instead of this institution being confined exclusively as heretofore to vagabonds found on the highway who are taken in and placed under a kind of penal *régime*, the asylum will in future receive those temporarily out of work and homeless who can go in and out freely. The proceeds of their work (when they get any) will go to defray the expenses of the institution.

Appointments.

Dr. Albert Calmette has recently been elected by 40 votes out of 47 a corresponding member of the Academy of Sciences. He is well known as the director of the Pasteur Institute at Lille. He commenced professional life as a medical officer in the colonial service and distinguished himself by carrying out a number of scientific researches which have had practical applications. Another appointment, and one which has attracted more attention in Paris, midwives with a full understanding that they would work at district midwifery for a certain number of years. Miss Gregory then explained in detail her scheme and observed that the National Training School for District Midwives would be commenced first of all by training a few midwives. Dr. C. J. Cullingworth thoroughly endorsed the views expressed and concluded his speech by thanking the Countess of Stamford for occupying the chair.

GENERAL HOSPITAL, BIRMINGHAM.—The 124th report of this institution states that during the year 1903 the number of in-patients treated was 5366, a decrease of 276 as compared with the previous year, but the daily average of patients in the hospital was 289¼, as against 288½ in 1903. Of the in-patients admitted 1128 were children under 12 years of age, of whom 206 were under two years. The out-patients were 64,926, or 2407 more than in the previous year. The number of operations performed was 2137. The amount accruing from subscriptions and extra tickets was £8002, only £152 more than in the previous year. The donations were £402, as compared with £436, and special congregational collections £57, as against £67. £6715 were placed to the credit of the current account as the moiety of legacies received during the year, as compared with £675 in the year 1902. The ordinary expenditure was £24,841 19*s.* 1*d.* and the extraordinary £117 0*s.* 1*d.*, while the sum of £332 1*s.* 7*d.* was transferred to the Jaffray branch account to meet the deficit at that institution, making a total of £25,298 16*s.* 1*d.* The adverse balance, £11,423 16*s.* 9*d.*, brought forward from the year 1902 has been reduced to £7302 18*s.* 0*d.* The board urgently appeals for new and increased subscriptions, for donations, and for bequests, so that the work of the hospital may be continued for the benefit of the sick and suffering in the Midlands.

THE REMOVAL OF KING'S COLLEGE HOSPITAL.—A meeting was held at the Mansion House on March 11th in furtherance of the appeal for funds to enable King's College Hospital to be removed to South London. The Lord Mayor presided and among those present were the Archbishop of Canterbury, the Bishop of Rochester, the Rev. A. C. Headlam, D.D. (Principal of King's College), Dr. David Ferrier, and Mr. W. Watson Cheyne. The Lord Mayor said that owing to the recent great changes in the character of the neighbourhood, coupled with the proximity of Charing Cross Hospital, there was no longer the same necessity as formerly for a large hospital in that locality. Great numbers of people who used to live in Drury lane and other streets adjoining the Strand had now gone elsewhere and on the whole there was little doubt but that the hospital would be more useful in Camberwell than on its present site. In Camberwell there was a considerable population of very poor persons to whom facilities for obtaining advice at a hospital would be a great blessing. Mr. W. F. D. Smith, M.P., said that the removal of the hospital had become imperative on account of the fact that the existing buildings in some respects fell short of modern requirements and extension of them was impossible. Moreover, the formation of a wide thoroughfare from Holborn to the Strand had necessitated the demolition of a great many houses and one result of these improvements would be the reduction of the population of the district by not less than 4000 persons. There were, in fact, at the present moment too many hospitals concentrated in Central London, while, on the other hand, South London was in great need of a general hospital. A sum of £300,000 would be required for the completion of the first portion of the buildings on the new site. It was intended to have a limited competition for plans for a hospital of 600 beds and Mr. Rowland Plumbe, F.R.I.B.A., had consented to act as assessor in the competition. The scheme had the approval of the authorities of the King's Hospital Fund, who had given a substantial donation. The Archbishop of Canterbury, at the conclusion of a sympathetic address, moved "that this meeting cordially approves of the scheme to remove King's College Hospital to South London and pledges itself to do its utmost to insure the success of the movement." Dr. Ferrier said that, as representing the medical staff of the hospital, he desired to refer briefly to a few special aspects of the case. It was only in great hospitals which were also educational institutions that medical practitioners could obtain practical training in the diagnosis and treatment of disease, and King's College Hospital, which had for many years ministered to the sick of a large poverty-stricken district, had also sent out thousands of qualified men to practise their profession in every part of the globe; many important additions to medical knowledge had also been made there. The medical and surgical staff were now unanimously of opinion that removal of the hospital to a more populous district such as Camberwell was advisable in the interests both of the poor and of the medical school. The motion, which was seconded by Mr. C. E. Tritton, M.P., and was also supported by the Bishop of Rochester and Mr. Watson Cheyne, was carried unanimously.

MEDICAL COUNTY COUNCILLORS.—Dr. George A. Cohen has been elected a county councillor on the Middlesex County Council for the Harringay division of Middlesex, and Mr. Horace Rose has been elected to the Bucks County Council for the Eastern division of Aylesbury.

DONATIONS AND BEQUESTS.—The Goldsmiths' Company has made a special grant of £750 to the Royal London Ophthalmic Hospital in response to the committee's centenary appeal.—By the will of Mr. Joseph Jackson of Rosebank, Scotforth, Lancashire, £300 are bequeathed to the Royal Lancaster Infirmary.—Mr. H. W. H. Faulenbach of Enfield, Middlesex, has by his will bequeathed £500 to the German Hospital, Dalston.

SOCIETY OF ARTS.—At a meeting of the Society of Arts, held on March 2nd, Dr. Robert Jones of the London County Asylum at Claybury in Essex read a paper on the Physical and Mental Deterioration of the Lower Classes of the British Population. Many of our readers will be aware that Dr. Jones maintains that this deterioration is on the increase. A copious exposition of his opinions appeared in THE LANCET of August 8th, 1903, p. 366. In the ensuing discussion, however, most of the speakers took a more favourable view of the circumstances. Sir William S. Church, who presided, said that it was universally admitted that public health was better at the end of the nineteenth century than at its beginning and if this belief were proved to be unfounded then the alleged progress and prosperity of the Victorian era must be a myth. Dr. Harry Campbell said that the subnormal physique of urban populations was due principally to the use of soft food which required little or no mastication. Dr. Campbell's views were published at length in several issues of THE LANCET in July and August, 1903. Dr. William Hall held that the evils complained of arose through mothers not suckling their infants. Sir Ralph Knox of the War Office, speaking of the arguments drawn from the recruiting returns, said that there had always been a large proportion of rejections and that a recruit after his first rejection often renewed his application elsewhere, so that his rejection appeared more than once in the returns.

THE PRUDENTIAL ASSURANCE COMPANY.—The directors of this assurance company have recently presented their fifty-fourth annual report which shows that the company is still making headway. The report shows in detail the separate finances of the ordinary branch and the industrial branch. The last-named branch includes all those millions of people who pay 1*d.* or a few pence per week which are collected by the army of agents of this company. The accounts for the year ending Dec. 31st, 1903, contain an item in this respect of £1,588,768 paid as salaries to 15,593 agents for the weekly collection of premiums from 14,287,406 policies in the industrial branch, and it is also interesting to note that in the same branch the medical fees paid are stated to be £55 875 1*s.* 9*d.* For the purposes of readily grasping the magnitude of the business we have added the figures for the two branches together and they show that for the year ending Dec. 31st, 1903, the premiums received amounted to £9,661,410, that the claims made amounted to £3,624,510, that the number of deaths was 217,450, that the policies in force at the end of the year numbered 15,912,487, that the total assets of the company on Dec. 31st, 1903, were valued at £51,217,377, and that the liability to shareholders was only £1,000,000. In this connexion it is interesting to note from the Insurance Blue Book and Guide for 1903-04 that the dividend on the shares, which are of £5 each, for the last financial year was 5 per cent. and that a bonus of 44*s.* per share was paid in 1902 and that the recent average price of the share was £65. It may be interesting to note that the assets of the company are chiefly invested in loans on county council, municipal and other rates, railway, gas, and water stocks, and mortgages on property within the United Kingdom.

THURSDAY, MARCH 10TH.

Committee on Physical Degeneration.

Sir JOHN GORST asked the Secretary to the Board of Education whether he would state what were the terms of reference to the

medical data for an accurate comparative estimate of the health and physique of the people; (2) to indicate generally the causes of such physical deterioration as does exist in certain classes; and (3) to point out the means by which it can be most effectually diminished.

Tuberculosis Commission.

Mr. FIELD asked the President of the Local Government Board whether he would state if it was the intention of the Tuberculosis Commission to issue an interim report and if so how soon it might be expected.—Mr. LONG answered: I understand that the Commission does not intend to issue an interim report.

Plague in India.

Mr. WEIR asked the Secretary of State for India to state the number of persons who died from plague in Central India and Rajputana respectively during January, 1903, and January, 1904.—Mr. BRODRICK replied: The numbers are: Central India, January, 1903, 92; and January, 1904, 3721. Rajputana, January, 1903, 10; and January, 1904, 716.

Mr. WEIR also asked what percentage of persons inoculated with serum in India subsequently died from plague.—Mr. BRODRICK replied: Calculated on the figures of inoculations and death in the several provinces given by my predecessor in office in reply to a question asked by the honourable Member on June 11th, 1903, the percentage of deaths is 0.24. I have no later information on the subject but the Government of India has lately taken steps to secure a more accurate record for the future.

Amendment of the Pharmacy Act.

Mr. O'MALLEY asked the First Lord of the Treasury whether he

rred to in the question. I have
slation but I cannot promise to
he present session.

Vaccination Statistics.

Answering Mr. WEIR, Mr. LONG said: According to the information *in statu pupillari* his conduct gave them no cause to revoke their leniency, we cannot think that the Colleges would be right to refuse their diplomas to him. No one is more anxious than we are to keep the ranks of the medical profession from the first day of registration as a medical student purged from all wrong-doers, but we cannot subscribe to the suggestion that a wrong-doer always remains a wrong-doer. The situation to which our correspondent "Jail-bird" has drawn attention can hardly ever occur, but if and when it does we do not believe that the profession as a whole would suffer by the adoption of the merciful view.

UNPLEASANTLY ENERGETIC.

WE have received from Port Adelaide, South Australia, the following card which leaves in our mind the impression that the medical man whose name we have suppressed, while energetic, has no very great opinion of the restrictions that usually regulate the conduct of members of the medical profession:—

Telephone No. ——. CONSULTATION HOURS:
10.30 a.m. to 1.30 p.m.

X——,
St. Vincent Street,
Right hand side of Railway Line, Main Street.

When required to visit Ship kindly Telephone by 9 A.M. if possible.

When sending a member of crew for advice please send order with him.

We are informed that these cards have been distributed to the various shipping offices of Port Adelaide and we have no hesitation in saying that, if such organised touting for business took place in this country, the medical man in question would be considered to have transgressed the laws of the profession against advertising. It has been alleged in these columns more than once that the rules of the General Medical Council, no less than the unwritten laws of the medical profession, have not and cannot have the same force in the colonies as they possess in the mother country. We appreciate that in some places different circumstances may excuse a laxer procedure, but we cannot imagine any excuse for the systematic attempt on the part of a medical man, through the distribution of business cards, to grab any private practice that the ships may bring into the port where he resides. And if X—— does not mean to do that by circulating his cards what is the object of his enterprise?

CARRIER PIGEONS.

IN an article on the breeding and training of the homing, or carrier pigeon the *Scientific American* of March 5th states that arrangements are being already made for a 500-mile pigeon race from Spartanburg in North Carolina to Philadelphia, to be held on July 4th. The greatest "record" for flight is 1603 yards in a minute. Two other passages from the article are as follows: "Clubs devoted to raising and improving the carriers are scattered in every state in the Union and their memberships are all large; but there are tens of thousands of individual breeders who do not belong to any association. Thousands of these breeders enter their home-raised pigeons in the races and sometimes win prizes which the professionals fail to capture. ...... Country physicians have in many instances adopted them as messengers. A physician raises a loft of carriers for the pleasure of it and when he visits a patient four or five miles away he carries with him a basket containing one of his birds. If dangerous symptoms arise in the night or the following day the pigeon is released with a message. Some physicians with long country routes carry half a dozen or more of these pigeons on their rounds and leave one at each place. A daily report of the different cases can thus be obtained by pigeon service at no cost to physician or patient."

THE CHARMING AWAY OF WARTS.

To the Editors of THE LANCET.

SIRS,—The following may afford amusement if not instruction to the readers of THE LANCET. A few days ago a charming young lady friend stopped me and begged me to come to her mother's house and charm away a batch of warts which *disfigured the hands of one of* their maids. I had the greatest difficulty to convince her that I possessed no such power and she was unmistakeably dissatisfied. Her faith in me as a wart charmer arose in this way. About 12 years ago, when this same young lady was a child of 14 years of age, she and her mother when driving beckoned to me from their carriage. They were on the look out for me for my opinion was wanted as to what should be done to a large number of warts on the hands of the child. There were over 20, about 12 or more on one hand, as far as I can remember, and about eight or more on the other. The child was at a sensitive age and keenly felt the disfigurement, for they were all on the back of the hands and they were ugly warts. They were so numerous and so large that I reluctantly declined to treat them. Quite in joke, however, but in order to make up for the evident disappointment, I said that I would charm them away. I took the child's hands in mine, rubbed them gently, and assured her, but with much earnestness, that in a short time they would all disappear. Within a fortnight they were gone and my surprise was as great as the child's delight.

I have always looked upon this as a mere coincidence and have no reason now to consider it in any other light. All authorities, however, agree that warts have some direct relation to the nervous system. They have been known to disappear under mental emotion and many old women have claimed the power of dispersing them. In the above case my earnestness no doubt made a solid impression on the child's mind. Could this have anything to do with their disappearance? I should be glad to know if any of your readers have had similar experience.

I am, Sirs, yours faithfully,
Windermere, March 13th, 1904. ARCHD. HAMILTON, M.D. Edin.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—For the benefit of those of your readers desiring to invest in automobiles and who are not fully acquainted with the numerous pitfalls as to make, finish, price, workmanship, durability, and newness or otherwise of engines fitted I recommend to them the services of Mr. G. Wilding, 100, Denbigh-street, who being independent of any vendor firm advises reliably on the above points for a moderate fee and with whose past services I have reason to be satisfied.

I am, Sirs, yours faithfully,
F. W. FORBES ROSS, M.D. Edin., F.R.C.S. Eng., &c.
Gower-street, W.C., March 14th, 1904.

RED NOSE.

M. E. writes: "*Can any reader kindly advise writer as to the best* treatment for red nose? My patient is a lady, aged 35. The nose is generally cold and there are frequently pustules forming on the alæ. The condition appears to be largely vaso-motor, the nose at times being less unsightly than at others. The only other affection is a profuse menstruation once a fortnight."

◆

Ubique.—1. The only justification B could have for taking the case from A's hands was knowledge that A was treating it unscientifically. As a matter of fact, from the statement made to us, A was treating the case perfectl correctly. 2. In accordance with this view A would be right, if he wished to do so, to abstain from professional relations with B, but we think that to do this would be unwise. Such a course weakens the medical profession as a whole and prolongs bad feeling. 3. We think that A is legally right to keep the half fee which has been paid to him as a retainer and probably the court would take this view. Would it not, however, be more dignified to return the money?

R. R.—(1) If the facts were proved to be as stated by our correspondent a county-court judge would, we think, be bound to hold that A employed the medical man to attend his servant and that having done so he was liable to pay him; (2) the fees named are, in our opinion, reasonable in the circumstances; (3) the county court, unless any local legal practitioner can supply any reason to the contrary, is the better court; (4) if the medical man recovers judgment the defendant will presumably be ordered to pay costs. The amount of the costs recoverable depends upon the amount of the judgment and upon what the judge may allow.

Os calcis.—There are several suitable books on the subject published in all the principal languages but Herman's "Diseases of Women" (Cassell and Co., price 25s.) is the book which we recommend in the Students' Number of THE LANCET and it would probably suit our correspondent's purpose.

R. P. is thanked for the prospectus. It has been issued broadcast to the medical profession. We doubt whether the medical man does reside at Sandgate and we consider his action in the matter open to serious professional question.

R. B. asks leave to hazard the suggestion that a writer in the columns of THE LANCET is a hypochondriacal patient endeavouring to obtain a free opinion. R. B. has evidently small appreciation of our acumen.

J. M.—There is no suitable book and it seems to us that to write one would be a very difficult task. Boys should be warned by their male relatives.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received: *Wellington Journal and Shrewsbury News, Catholic Times, Macclesfield Courier and Herald, Bolton Evening News, Western Daily Press, Evening Leader (Newcastle), Reading Mercury, Herts Advertiser, Times of India, Aberdeen Weekly Free Press, Daily Mail, South Wales Echo, Westminster Gazette, Dublin* [illegible] *Hertfordshire* [illegible] *Echo, Brad-* [illegible] *Windsor and*
